At the moment it is impossible for many of these schools to attract and hold really competent teachers. Maybe we should have a Government Science Corps in which there are people who can move in and out of these smaller institutions, who can also work in the Government laboratories, can be science attachés abroad, or work part time in the bigger universities and in industry so they can stay current.

I can't recommend the proper organizational invention here, but the problem is certainly one of our very serious ones.

Finally, a number of the previous witnesses talked about international science activities and the roles of the NSF in them. I personally believe the NSF should be encouraged to play a bigger role in the international scientific field. There is a great deal of merit in exploring more cooperative projects.

An obvious reason for cooperation is that some activities are getting so big that it is desirable to share the cost internationally.

There are many other advantages in cooperating with the mature countries, particular advantages both from the point of view of the nations themselves and from our point of view. There are also many reasons for having modest cooperative activities which don't have the stigma of aid, with some of the scientists in the developing countries, and I believe that the NSF ought to be encouraged to play a role in this field.

Mr. Chairman, I have rambled over a whole series of subjects. I probably should stop and let you pin me down on the questions that are on your mind.

Mr. Daddario. You have talked about the research going on in the various agencies, and the fact that the National Science Foundation

should play a larger, if not indeed the dominant, role. How do you bring this about, considering the attraction there is in such agencies as the Department of Defense and NASA?

Dr. WIESNER. Well, first of all, the Science Foundation itself should not become involved in directly carrying out research. I don't believe the Science Foundation should have its own laboratories such as NASA, the DOD, the AEC, and the Department of Commerce have, so it doesn't have a need for large full-time research staffs. It obviously needs some extremely able people to plan policy, to approve and monitor programs and so on, but the staff needs in the Science Foundation are much smaller than they are in the DOD.

The important thing to do here is to make it clear in terms of both policy and support that the National Science Foundation is one regarded as one of the dominant agencies in the creation of policy for basic research and in its support. The only way to do this is to support much of the research we are talking about through the National Science Foundation.

I believe that as the responsibilities of the Science Foundation grow, its stature and its power will grow. I don't think you can legislate this by just—in fact, this was tried in the original National Science Foundation legislation. The NSF was given a great number of responsibilities and powers, which its Director found he was not able to exercise from his relatively minor position in the Government scientific hierarchy. But, as in recent years, the support for the National Science Foundation has grown and so has its stature and its importance. I think that is the way we should continue to strengthen the NSF.

There are a number of important research fields that could be supported in several ways. All things being equal, we should give priority in the broad general fields of science to support through the route of the National Science Foundation, but taking care, as I said earlier, to be sure that we do not stifle or seriously damage the research components of the other agencies. I regard this as a very great hazard that we must avoid.

Mr. DADDARIO. As the National Science Foundation has grown, it has played a bigger role, and it still needs to play a bigger one, according to your statement. How is it staffed to meet this new challenge? Is it large enough? Could you relate the size of the staff to the Director and the National Science Board?

Dr. WIESNER. I certainly believe that in some areas the Science Foundation's staff should be increased, augmented. There is no question about the fact that its responsibilities have grown faster than the staff has grown to support them, and if you continue to support the Science Foundation and its activities continue to grow, it is obviously going to have increasing staff needs.

It has some unresolved problems which in part relate to people and in part relate to policy issues which are still unresolved. There is the problem of how one supports large scientific projects, for example. This seems not to be fully and satisfactorily resolved. I know that the Director is aware of this. He got his baptism in the Science Foundation trying to wrestle with the Mohole project, and he recognized that the procedures that are fine when you are dealing with modest grants, even substantial grants, are not adequate to manage multimillion-

dollar individual projects. In some of these areas that I have talked about, such as the educational research and development field, I have been critical in the past of the Science Foundation's lack of aggressiveness. I think this comes about because the staff in these areas has been overworked, and here a few more people there might lead to more activity.

I want to make it clear that I think the Science Foundation has done a good job as is reported in the various papers that discuss its activities, but I think the opportunities are so great that one ought to press them a good deal harder.

The question of the relationship between the Board and the Director is one about which there have been substantial differences of opinion. I personally believe the Director's hand should be strengthened. The situation has never been serious because the relationships between the directors and the Board I think has always been good.

On the other hand, there has been a certain amount of ambiguity. If the Board insisted on functioning with its full responsibilities or tried to review all of the grants and projects, it would find it an impossible job for a part-time board. In fact, the Board has delegated most of the detailed responsibility to the Director and his staff. We recommended, during the development of Reorganization Act No. 2, that the Board be made policy adviser and that all of the operating responsibilities be given by law directly to the Director, rather than being delegated by the Board. Several Board members objected with sufficient violence and with a sufficient number of arguments that I concluded that they might be right and I didn't pursue it. I still think this is a point that is worth considering and examining.

I think if you want to attract an outstanding scientist, such as Dr. Haworth, as Director of the Foundation, one should be prepared to give him the maximum amount of responsibility, just as we do the other operating heads of executive agencies in the Government.

On the other hand, because of the complicated relationships existing between the universities and the Government, and the fact that a certain amount of isolation from autocratic Government decisions is desirable in this particular area, the Board should be left with a great deal of power in the policy field.

My first reaction to the proposal for a full-time Chairman of the Board made by Dr. Walker, is negative.

Mr. DADDARIO. If there were to be a full-time Board, should there be a full-time staff?

Dr. WIESNER. I don't see how you can operate with a full-time chairman and a full-time staff. I think that all you would succeed in doing by this change would be to make the Director subordinate to the full-time Chairman of the Board. I think this would add an echelon of management without really accomplishing anything.

Mr. DADDARIO. Can you separate the functions?

Dr. WIESNER. I have not thought about this particular proposal in great detail. I saw it only yesterday when I read these documents, and there may be reasons for it of which I am not aware.

On the other hand, I think to argue by analogy with industrial corporations, or even MIT, as Dr. Walker does, is really a bad mistake.

Few corporations run successfully with a full-time chairman of the board and a president, unless one or the other is clearly the operating

head. At MIT the situation is unusually fortunate. The president and the chairman, as a result of a great many years of association, do work very well together. This has been particularly good for MIT. But most of us recognize that this is a fortunate accident, and it is unlikely that one could run a university this way ordinarily.

To draw any general conclusions about the feasibility of running the National Science Foundation this way from the MIT experience would be a very serious mistake.

I have less strong feelings about a full-time staff for the board. If there is a full-time staff, its responsibilities should be very carefully limited; otherwise one would end up with two groups trying to run the Science Foundation. I am sure that the Board could profitably use more information which might be provided by a small amount of staff assistance. I would be very much concerned about a second layer of management, whether you say it is policymaking or operational, of the kind that is proposed by Dr. Walker.

Mr. DADDARIO. What did you have in mind, Dr. Wiesner, when you said the Director's hand ought to be strengthened?

Dr. WIESNER. In the Reorganization Act No. 2, in which the relationships between the National Science Foundation and the Office of Science and Technology were established, we also tried to raise the bureaucratic level of the Director, so that he had the same prerogatives and stature and responsibilities in the Government as other agency heads. We were not able to do this because of the fact that many of the responsibilities that an ordinary agency has reside at least normally by law in the Board, rather than the Director, and the Director is in many ways the agent for the Board, rather than the executive officer reporting to the President. In practice, actually, the Director has always been essentially an agent of the President, because the fiscal control which the President has is a pretty powerful form of control. So there has never been a problem, per se, as a result of this. But it is an anomaly—the Director essentially has all the responsibility, he gets all the blame if things go wrong, because the Board cannot exercise fiscal control or operations, but yet normally it has many of these responsibilities.

It would seem to me that it would be better to have provided the Director with these clear-cut operating responsibilities and limited the Board's responsibility to the policymaking.

Now, at the time of the reorganization some members of the Board felt very strongly that this is not right. I happen to feel that it would be a better, cleaner cut manner of operating if the Director had the full operating responsibility. But I know that at that time many of the members of the Board felt that the Science Foundation would not function as effectively. Some members of the Board even indicated that they would not serve on a board whose powers were greatly restricted. So it was an issue that would have been hotly contested if we had chose to do anything about it.

As I say, I, in the end, chose not to try to do it, because I thought we were right. I also felt that the problems that it would generate were more serious than the ones that it would cure.

Mr. DADDARIO. As the Science Foundation faces this ever-increasing role that you have been talking about, have we reached the point where the relationship of the National Science Board to the Director, and the Director's relationship with his staff should be reviewed?

Dr. WIESNER. The Board, itself, and the Science Foundation staff have had such a review. As a matter of fact, the Board has changed its structure. It now has three subcommittees, which I know you have heard about, established in an attempt to meet the growing effort. As far as I know, this is operating satisfactorily.

I am not aware of a need for a major overhaul of the structure but rather for an increased staff support within the Foundation. One other thing which I should have mentioned—the problem Dr. Wolfle talked about at considerable length—the matter of providing adequate information for making decisions. I think this is one of the more serious problems in the Government as a whole. The Science Foundation has, and has done reasonably well at this, particularly in recent years, but I think, seen from the Federal Government's point of view, the information about scientific activities and scientific manpower is not adequate. This is both a problem within the Science Foundation—the more information the Board and the Director and the staff have, the better they will be able to do their job—and for people at the presidential level, the Office of Science and Technology, the Bureau of the Budget, and other groups. I believe that the recommendations that Dr. Wolfle makes should be considered very seriously and we should make an effort to strengthen that particular aspect of the science management activity in the Foundation.

Mr. DADDARIO. Mr. Roush?

Mr. ROUSH. Mr. Chairman, I think Dr. Wiesner's off-the-cuff remarks are apparently the result of a great deal of wisdom and experience. They have made a real contribution to these hearings. Because they were off the cuff, perhaps some things crept into his remarks which he would not have placed in written testimony. I am very grateful for this opportunity to hear him.

You mentioned the behavioral sciences as one area which is not receiving enough attention. You also mentioned in this connection other agencies and their apparent lack of interest in this field. Is this is an area in which you feel the National Science Foundation should, or could, pay more attention?

Dr. WIESNER. Yes. It has been talked about a great deal, and, as I have indicated, in the last 4 or 5 years the Science Foundation has picked up activities in the behavioral sciences.

The closer one gets to the social behavior of human beings, the more skittish the Science Foundation has been about getting involved, because they are obviously getting further and further away from the physical sciences. Even the National Institutes of Health have been somewhat reluctant to get into these fields, and probably with good reason. These, in a sense, are beyond the normal interpretation of their missions, and there are fields where it is often hard to judge what is good and what is bad.

Mr. ROUSH. Isn't it, Dr. Wiesner, that we are going beyond the image which the people in Government and the people in education have of the National Science Foundation, rather than it is in going beyond its mission as has been set out by the Congress?

Dr. WIESNER. I think that the problem stems from the way we interpret the word "science" in this country. If we had the Russian or European interpretation of "science," which is just the development of knowledge, this probably wouldn't exist. All of us who have dealt with some of the foreign academies of science are surprised to

find historians, economists, political scientists, as full-fledged members of their academies of science. I think this is unfortunate in our country for this separation has generated a split among intellectuals which is undesirable. I think you are right, it is as much the image of what the words actually mean.

I think there is another problem that one ought to put on the table. At least in times past people have been concerned about doing research in social sciences because of their fears of Congress, a fear that Congress will think they are trying to manipulate public opinion or change the society. This has been very genuine, a fear for people having responsibility in big programs, and who don't want to get their agencies in trouble supporting what they regard peripheral activities. Anyone who is really candid with you will admit that this has been a factor in some elements of the social sciences.

Mr. ROUSH. My question has been prompted by an interest that I have in what I think is one of our real great national problems, and that is our crime problem. I have the natural interest of a citizen and a legislator, but this also has been stimulated by 4 years of activity as a prosecuting attorney. In the last couple of years, I have been trying to do some background work with the view of introducing legislation dealing with this great national problem. I have found that there is practically no research being done now in this area of human behavior.

I think it should be done. I am trying to find out who should be doing it, and why we haven't been doing more in this area.

Dr. WIESNER. I agree with you. At one time, while I was working down here, we became deeply involved in the narcotics question and we looked at the research and development activities attempting to understand the medical and social problems of addiction, and we were horrified to find that this was an area where no one was doing serious work in an attempt to understand either the biological or medical aspects of narcotic addiction. When I say "no one," I am exaggerating, but the amount of effort was comparatively small in comparison to the problem that we are facing, and I think this is also true of the field you are talking about. It is much harder to do research in these fields than in the physical sciences. They are much more complicated problems, so people shy away from them.

The image in these fields is also responsible for this. When I was working on the White House staff, people used to say the Government isn't supporting behavioral sciences adequately. I got us a group of behavioral scientists to form a panel for me to tell me what they needed. They didn't really know. They were so convinced they couldn't get support that they never bothered to try to get support. I think there is a "chicken and egg" problem in many of these fields. To a certain extent that has been resolved by support from the NSF and from the NIH, but I am sure more encouragement in these fields is badly needed.

Mr. ROUSH. That is all I have, Mr. Chairman.

Mr. DADDARIO. Mr. Conable?

Mr. CONABLE. Doctor, you said at one point that the National Science Foundation was not playing the dominant role that it should. You also have mentioned your fear of bureaucratic control in this area.

Are you talking about this not being a dominant role purely in a quantitative sense?

Dr. WIESNER. No. But I think they are very much related, as I said. I think the ability to make policy and to influence policy and to determine what directions are followed is closely related to your responsibility for support. But I certainly was thinking at least as much about the role of the National Science Foundation in broad national policy in basic research as I was about fiscal responsibility, though I am certainly recommending that they be given a larger share of the fiscal responsibility for basic research as our programs grow.

Now, just to elaborate a little on one point of your question, I think the Science Foundation was initially given responsibilities to do things which we later concluded it should not have been asked to do. That is to have the coordinating responsibility over areas that are the responsibility of other departments of the Government. This is the role which, as an operating agency, as a funding agency, we concluded it could not really play. It can play an advisory role, a statistical-gathering role, a leadership role, but it cannot play the kind of Government-wide decisionmaking and coordinating role that was originally visualized for it.

Mr. CONABLE. This is the point of my question, Doctor. Do you feel the National Science Foundation should recapture some of this coordinating function that it has lost to the Office of Science and Technology?

Dr. WIESNER. I don't think so. I believe that the advisory and management structure that has been developed is satisfactory. You see, one of the problems, whether you are dealing with the Science Foundation or the Defense Department or the Atomic Energy Commission, is that once the agency becomes a funding agency it is a vested interest, and no matter how hard its director and staff try to be impartial, they must respond to internal pressures of their agency. One need that led to the development of the Office of Science and Technology and the Science Advisory Committee and their supporting whole structure was the President's need for some people whose loyalty was basically to him, and not to the missions or the agencies.

As the Science Foundation grows, its internal responsibilities will grow too, and it should be in a position to concentrate on those and be an advocate of its programs and its positions. To ask the Director of the Science Foundation to give the President impartial advice on problems that involve the Science Foundation is asking for a lot. But there is an even more important point. The President needs advice on a broad range of problems that involve science and technology that go way beyond the scope of the Science Foundation—foreign policy, defense, and so on—and the structure which exists is one that deals with the full range of the President's problems, and there the basic research activities are just a small part.

Mr. CONABLE. You also mentioned computers and the serious problems that our schools were having, essentially because they could not provide them because of the cost. Do you know if the National Science Foundation has made institutional grants for this purpose?

Dr. WIESNER. Oh, yes, the Science Foundation has funds for supporting institutions, but I think the problem is several times the scale of the Science Foundation's resources to deal with.

First of all, it hasn't the resources to provide the computers that are needed.

In addition, I don't believe anyone has thought through the second and more difficult problem which I mentioned, which is how to provide the resources to use computers in education, rather than in research. I am not even sure the Science Foundation would feel that that is an appropriate role for it, but it is a serious problem and it needs to be explored, or the country is going to be turning out youngsters whose education falls short of what it could be, by quite a bit, in this area.

Mr. Conable. One other question having to do with manpower: If the National Science Foundation continues to grow at the rate of 15 percent or more a year, do you see any problems relative to the availability of high-quality scientific personnel? Do you feel that we would be getting too much of our scientific manpower over into basic research, or is the supply growing sufficiently fast so that we won't have any shortages as a result of this?

Dr. Wiesner. This is a question about which it is hard to get good facts. The Government has tried, over the last half dozen years, to come to grips with this question. While I worked here I oscillated violently between believing that we were creating terrible manpower shortages and feeling that we were running a danger of creating an oversupply. Every time we got some new data, we oscillated between these two extremes. It is because the labor market is so flexible; that is, when you create more jobs by starting scientific activities you attract people who have been doing other things.

I think one has to admit that you generate sufficient demand you attract people who are inadequately trained.

I think the best judgment at the moment, as far as basic research is concerned, is that the country has enough trained people who can do good scientific work that we are not in danger of manpower shortages. In fact as the population grows, as our productivity increases, we should be glad to have these job opportunities for people to go into rather than to fear that we are draining off too large a fraction of the manpower into these activities. I must say this is a judgment that is based largely on looking at actual data and talking to people, rather than any hard facts that I could muster to prove my point.

Mr. Conable. That is all, Mr. Chairman.

Mr. Daddario. Mr. Davis?

Mr. Davis. Dr. Wiesner, I want to join with the sentiments expressed by Mr. Roush a few moments ago. I have thoroughly enjoyed your statement this morning and have gotten a lot out of it.

You have stated that the universities could use more computer facilities. Is it true that if industry had a lot more computers available, it could proceed with automation at a tremendously accelerated pace?

Dr. Wiesner. I don't feel competent to answer that question.

I will make some random observations, but I do it with a certain amount of hesitancy. I believe that some industries are really introducing computers about as fast as they have the ability to absorb the change. Certainly, the automobile industry is doing a lot of experimentation in this area. More of it is in the accounting and control activities than in the actual manufacturing process, at the moment.

But we also have computers running an increasing number of production machines. We are also using computers more and more in engineering activities. This is certainly true in the aerospace and electronic industries. The telephone industry is going over to switching that is computer controlled about as rapidly as it can.

On the other hand, there are many industries that are traditionally not used to employing technology at all, not only for automation, but just to make better products. It is only recently that automatic controls have been used extensively in ships, and I don't think they have been fully exploited. If we want to have a competitive marine industry, we should try to automate our ships so that smaller crews would be required.

Professionals who know about this—and I am not an expert in this field, tell me that in the shipbuilding industries overseas, in the Scandinavian countries, in Japan, and Germany, automation is employed more extensively than here, so that we are fighting against losing odds with obsolete technology and a higher cost labor force when we build ships here.

So there are clearly areas where one could do a great deal more.

Mr. DAVIS. The textile industry, for example, where there are lots of repetitive tasks, is pretty well subject to being automated, isn't it?

Dr. WIESNER. The textile industry is a strange one. I once had it studied. Some of the things which must be done, while repetitive, take a degree of intelligence that at the moment is beyond the sensors of computers that we know how to make.

This certainly will change. I was impressed by the fact that there wasn't much effort being made to couple computers and either looms or other textile machines. I tried to find out why this was, and came to the conclusion, I am not certain I am correct, it was a superficial look, and could have been wrong, that the structure of the industry with so many small units and very few large companies, was such that it was not possible to set up large-scale research and development activities. We tried on a number of occasions to stimulate something in this general field. Herb Holloman can show you a lot of scars that he acquired when he has tried to stimulate research in industry.

Industry didn't appear terribly anxious to be encouraged to do these things. I don't know why this was. Perhaps they are comfortable in their present position. In any event there was a fair amount of opposition to the Government's attempts to stimulate R. & D. in several industries. I don't honestly know how much can be done. Several times I have asked people in the clothing industry whether one couldn't develop a machine in which a computer directed a loom, so that the product was a suit, rather than a piece of cloth that then had to be cut and made into a suit. So far as I know, no one has ever tried to do this. There are probably a great many opportunities of this kind.

Mr. DAVIS. One situation that impresses me as being true is that with the progress we are making in converting our natural resources into the things we need with less and less human effort, less and less expenditure of manpower, two things happen: No. 1, the less privileged elements in the population realize there are enough assets to go around,

so it breeds unrest; and, No. 2, the set of values that our culture gives us becomes irrelevant. For both of those reasons it impresses me as imperative that far more effort go into the social sciences.

Dr. WIESNER. I think that is right. I think as far as the United States is concerned at least, this will be our No. 1 problem, providing we survive the arms race.

I believe that this matter of setting goals and ambitions among the kinds of life which technology permits is probably the key problem that we face, but whether this will come about as a result of social science studies or whether it has to come from spiritual understanding and leadership, or a combination of both is something I can't say.

We need to give a great deal more time and thought to this. I believe that the key to all of this is education. That is why I feel so strongly that more education, not just in science but general education, better understandings of ourselves, or history, the world we live in and the opportunities we have, are needed by everyone.

It seems to me the thing which we are recognizing now in this country is the point that Ken Galbraith made a number of years ago in "The Affluent Society," that we are no longer a nation that has to run on an economy of scarcity. We can do all the things we need to do to make a satisfactory life for all if we are intelligent enough to use our capabilities.

As our productivity increases and we have more people, we should be able to have more and better teachers, better medical care, better parks, et cetera. The opportunities for doing things are unlimited provided we can figure out how to use our resources properly.

Mr. DAVIS. That is all.

Mr. DADDARIO. Just following up Mr. Davis' questioning, Dr. Wiesner, you talk about the importance of education. The National Science Foundation science program support for fiscal year 1965 shows there is $280 million going into research, that includes $38 million in facilities, and $120 million in science education.

Is this disparity between these two cause for concern, especially in regard to the answer you gave to Mr. Davis' last question?

Dr. WIESNER. I haven't seen these budget figures, and I don't know what the money is for. What I am most concerned about is that we press as hard as we can in what I would call the innovation field. We call it research and education, but it is much more like engineering and development, trying to develop better curriculums, better understandings of how to teach, trying to use modern technologies that are available to the greatest extent.

I have not seen the 1966 budget breakdown, so it is conceivable that my worries would be less severe this year than they were last. Certainly during the period when I was deeply involved in the budgets of the Science Foundation I felt that the money for education was too severely restricted. The problem is, of course, that the Board and the Director have a whole series of objectives, and even though I may believe that education required more support, the Board felt that its single most important mission was the support of basic research.

In my opinion in that period we did not support educational research and development adequately, and I felt it was not supported adequately last year. I don't know about this year's funding so I am not in a position to comment on it.

There are tremendous opportunities here, and I believe that as a country we have been slow to recognize this fact. This is not in the NSF's primary responsibility, and I am not trying to blame them for the neglect. The Office of Education is much more at fault.

We spend about $30 billion a year on education. We once added up all expenditures by industry as well as the Government on research and development in education and it turns out to be a hundred million dollars; that is, 2 years ago we were spending only $100 million a year on the research to support a $30 billion industry.

No automobile company or other modern industry could survive with so small a share of its resources going into improving its product. It is only because its customers haven't any other place to go that the educational system gets away with this. If there were two school systems and some competition, I don't think this situation would persist very long. The Federal Government's responsibility arises because there are no normal market motivations to finance educational developments.

Mr. DADDARIO. The railroads have competition, but they probably put in about the same amount——

Dr. WIESNER. And they are slowly going out of business.

Mr. DADDARIO. Mr. Waggonner.

Mr. WAGGONNER. Dr. Wiesner, you spoke a moment ago about the shipbuilding industry in Europe and Japan. I had the privilege Sunday a week ago of visiting a highly automatic yard in Yokohama, Japan. I found a yard in Yokohama which is building large 150,000-ton tankers for American industry. Of course, it is much larger than anything else that it has done before. This yard only employs 1,200 people. They are working three 8-hour shifts a day. There are some areas automated and some not. They are automated to the extent that they have one central pipe rack. One can walk up and push a button for a piece of 6-inch pipe and down it comes. Then push another button after setting some control dials and it cuts a section at a 45-foot angle. Certain other areas are not automated at all.

I asked them why they had automated parts of the yard and not others. They said they had only automated those areas wherein the net return from automation would exceed the net return from utilizing manpower. I think they might have a simple guideline there that is quite good.

Dr. WIESNER. Of course, that situation is changing rapidly in Japan, because wages are going up very rapidly. I spent some time looking at the electronics industry in Japan 2 years ago, and I found exactly the same situation. The balance between automation and labor use compared to our best industry was on the side of using semiskilled labor rather than automation. But a shift is taking place there because the cost of labor is going up.

Mr. WAGGONNER. I agree with the previous comments that your remarks have been extremely good and helpful to us. Not that prepared statements aren't good, because they do paint the entire picture, but it does us good from time to time to have an impromptu commentary such as you have given us this morning.

Among the things you said is the fact that certain people over the country have grown impatient with the rate of growth that has been

experienced by the National Science Foundation. Would you tell me whether you share that impatience or not?

Dr. WIESNER. Certainly I do. But as a matter of fact, I would say this, I think the situation has been a great deal better in the past 5 or 6 or 7 years. This has come about as a result of the maturing of the scientific community and the recognition that, while the nature of the military support of research in this country was quite good, there were so many other objectives that one shouldn't depend entirely upon the military. The problem really was that it took so long for the Science Foundation to get off the ground rather than that the recent growth has been too bad. Even in recent years, though, the growth rate has been inadequate.

I think we haven't really fully compensated for the troubles of those early years. In other words, if there had been a reasonable growth in the first decade of the Science Foundation's existence, the situation would be a lot better than it is today. But, as I said, that we have gained a great deal of ground in recent years.

Mr. WAGGONNER. Of course, we all realize that the rate of growth which they have experienced had its limitations over and beyond their control in certain instances.

Dr. WIESNER. Oh, yes. I am not blaming the Science Foundation. I think other branches of the Government are much more responsible than the Foundation. The Foundation has known what it would like to do but it has not been supported.

Mr. WAGGONNER. You made the observation that perhaps the National Science Foundation, and of course I presume you mean their board and the director, should have more latitude in the international arena. You mentioned specifically cooperative programs. Did you intend to include as well that the National Science Foundation assume some responsibility in providing leadership in education abroad as they do here at home?

Dr. WIESNER. I didn't have education in mind but I think it should be included. I have seen, for example, in India the great impact of some of the National Science Foundation programs on education in the high schools and colleges in there, and this has come about in a very casual way. Much more of this would be helpful. The Science Foundation has not been in a position to give as much assistance overseas as desired.

This is a field in which assistance can be provided through other agencies involving the Science Foundation. For instance, AID can ask the Science Foundation for help. So I am not sure the NSF should be in a position to take the initiative. But there are areas in which the cooperation should really be undertaken primarily for scientific reasons rather than to assist the development of a country.

I think the spirit of the cooperation and the attitudes of the people involved in the cooperating countries will be very much better if it is done through the Foundation rather than through a development agency.

Mr. WAGGONNER. You commented as well that there were certain fields of research and educational advancements that you felt had been neglected in relation to others. Do you feel that the concept of the responsibility of the National Science Foundation has matured to the point that the Foundation, in conjunction with other available agen-

cies, can now establish percentages of money to be allocated to the various fields for which there is some responsibility?

Dr. WIESNER. I think so, yes. I think that the mechanisms for doing this are really fairly good at the moment.

Mr. WAGGONNER. In other words, we can relate the priorities of the needs of one field of research to another?

Dr. WIESNER. I don't like to use the word "priorities." I think it is very dangerous to say that one field of basic research is a higher priority than another.

Mr. WAGGONNER. Of course, that is what we have when we allocate percentagewise more money to one area than another.

Dr. WIESNER. Not necessarily, because there can be a field of great importance where the cost of research is not very costly.

If one were to try to relate certain fields of mathematical research where no equipment and just a few people are needed the field of high energy physics where every new machine doubles in cost, and we are now talking about machines that cost several hundred million dollars, we find how impossible this is. I wouldn't want to say that mathematics has a priority over high-energy physics.

We have to follow the method that Dr. Haworth indicated in his presentation, that is to examine the individual proposals and ask whether they are good or bad.

Actually, for administrative reasons it is necessary to allocate money by areas, and you could say in this sense that we are establishing priorities. But you be sure that you are not supporting relatively unimportant and poor quality work in one field while you are underfunding another.

I think fiscal allocations should be made in this loose and repetitive way, rather than by setting hard and fast priorities a priori. The Government process is sloppier and it is harder to do this way than if you just allocated sums of money because somebody's judgment said this field is more important than another. But I believe that the result is better.

Mr. WAGGONNER. You commented on the fact that you thought perhaps the ultimate answer to our problems would lie with education. I would to some extent agree with you, in that certainly we can find a direct relationship between our educational progress and our related accomplishments. This leads me to ask the question. Do you feel in view of what you have said that the National Science Foundation could not logically coordinate the scientific efforts which the Government undertakes—do you feel that the primary function of the National Science Foundation should be one of providing leadership, support and guidance to improve science education?

Dr. WIESNER. I think its primary function should remain the support and stimulation of basic research in the United States. But this is so closely related to the problem of science education that I think the two can't really be separated.

I think the Science Foundation's No. 1 and primary mission ought to be to preserve and stimulate the development of our basic scientific activities, our national basic research effort. This can't be done without education in the sciences. So I think they are inseparable. Furthermore it should be realized that most graduate research is also graduate teaching.

I wouldn't like to give the education a priority higher than the science, that is, the science and the research itself.

Mr. WAGGONNER. I am not going to ask that you attempt to answer this question here, but I would like for you to provide an answer for the record to this question.

Having asked the question about whether or not the National Science Foundation should have primary responsibility in providing leadership, support, and guidance to improve science education, you have commented on their inability under existing organization to provide the coordination that some people feel they should provide. Will you provide for the record what you think the end result of reorganization along these lines would be?

Suppose that the President has a science adviser in the capacity in which you once served, and in which Dr. Hornig now serves; suppose that the Office of Science and Technology was combined with the National Science Foundation; and suppose the President's science adviser served as Chairman of that Board; and suppose the National Science Foundation has a Director, as they now have. In addition, it is understood that this talked of reorganization was charged with the responsibility of not only providing leadership and guidance in the field of science education, but also of coordinating the scientific research of the Federal Government, giving special emphasis to using the capabilities of the mission-oriented agencies, such as the National Institutes of Health, the Department of Defense, the National Aeronautics and Space Administration, et cetera. Would you provide for the record what you think would be the pros and cons of such an organization, and what would be the end result in your opinion?

Dr. WIESNER. All right.

Mr. WAGGONNER. Thank you, Mr. Chairman.

(The information requested, is as follows:)

As I have already stated, I believe that the position of the Special Assistant to the President for Science and Technology should not be combined with that of the Director of the NSF. Many people have proposed some such consolidation. One popular and often advocated, scheme is the establishment of a Department of Science which would have responsibility for all basic research financed by the Federal Government. The agency head might be given Cabinet status and would also serve as the President's Science Adviser. Then the President's Science Advisory Committee and the President's Special Assistant for Science and Technology would no longer be needed because the coordination they provide would be assured automatically. The present structure leaves most of the decisionmaking and management of Government scientific programs up to the individual agencies, and arrangement which I am in favor of.

While I believe some of the arguments for a Department of Science have an element of validity and would support an effort to bring together some governmental activities that are not closely tied to agency missions, the proposal to collect all Government-supported basic science into a single agency is not the answer. First, intimate contact with basic research is essential for those agencies whose missions depend significantly upon technology.

Second, the new Department would be a major proponent of scientific programs, and its Director could not be expected to give objective advice to the executive branch on issues in which the Department had a major stake. Nor could he successfully serve as critic and judge of the technical programs of the other departments. The role of an independent Special Assistant for Science and Technology would be made more difficult by this move.

I also have a subjective objection to the proposal. As I stated earlier, I am afraid of too much centralization and control. I believe that the multiplicity of agencies funding basic research, and in a a sense competing, has been a significant source of strength in the U.S. scientific program, and is a feature which should be preserved.

Mr. DADDARIO. Mr. Brown.

Mr. BROWN. I would like to ask just one question. With regard to this need for increasing emphasis in the two areas that you have mentioned—the engineering sciences and the social sciences—do you think it would be helpful specifically to delineate in the National Science Foundation Act the responsibility of the National Science Foundation within these areas?

For example, now the mandate in the social sciences is merely included under the term "other sciences," and there is no specific delineation.

Dr. WIESNER. I don't know how to answer that question. If I was serving in an official capacity, I would say no, we can do it, and we don't want to be ordered to do it. On the other hand I believe that stimulation from a group such as yours can on occasion get something done that wasn't being done.

I would think that one wouldn't have to make a change in the Science Foundation Act, but if the committee felt this was an important task and said so, the Science Foundation would undoubtedly respond. You should really ask Dr. Haworth the question rather than me.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. Dr. Wiesner, you covered a very large number of subjects and, as has been said by the chairman you have done an excellent job. I agree with many of your remarks.

I have some very specific subjects that I want to take up.

In regard to the role of the National Science Board to the Director, and the Scientific Adviser to the President, what is the channel of fiscal control? Suppose, for example, that the Office of the President decided that the budget for the year should carry certain projects and the Board concluded to the opposite. I can imagine such projects being canceled out; that is to say, the solution might lie in everyone backing down rather than carrying this to conclusion in a positive way. Have such contentions occurred in the past in the operations of the National Science Foundation where fiscal control is exercised directly out of the Office of the President or the Budget Bureau at least through or passed the Board?

Dr. WIESNER. I doubt that fiscal control has ever been used to stop a specific project that somebody objected to, but fiscal control is exercised all through the Government by the President through the Bureau of the Budget, and for scientific activities, by the Bureau of the Budget and the Office of Science and Technology, largely because the projects that are submitted to the President usually cost 40 or 50 percent more than the President feels the budget can stand, and this is just as true in science as——

Mr. VIVIAN. Is the Board independent in any real sense?

Dr. WIESNER. No. The budgets are normally supported by the Director of the Science Foundation having been approved by the Board in advance. The Director of the Budget Bureau works with the Director of the National Science Foundation. Usually, when adjustments have to be made, these are made with cooperation. Sometimes the Bureau of the Budget or the Office of Science and Technology will have a different view about where changes ought to be made than the Director of the Science Foundation, but this is also true in dealing with the Atomic Energy Commission and the Department of Defense too.

Mr. VIVIAN. In the typical situation, is there a direct line of responsibility from the President to the agency's head and from the Bureau of the Budget?

Dr. WIESNER. As the Science Foundation operates, it is no different. The Director's relationship to the President and the Bureau of the Budget are essentially the same.

Mr. VIVIAN. The Director does not report to the Board in the context of budget actions?

Dr. WIESNER. He certainly has the Board approval. But the Board does not submit the budget to the Bureau of the Budget.

Mr. VIVIAN. I ask these questions because of the comment you made that you thought it might be well to make the Board an advisory board. I thought this would be a wise step to clarify what the reality is.

Dr. WIESNER. Just to present the other side of the question, because I think there are some very real issues, even though you and I are on the same side of the question.

The reason for the establishment of a Science Foundation rather than a Department of Science or some other move, the normal Federal agency operating, was to isolate the support of science from direct Federal control because of the fear that there could be too much governmental direction, domination, or control of our academic institutions through this very powerful device.

As a matter of fact, as you probably know, the original proposals for the National Science Foundation called for the creation of a very much more isolated Foundation than the present one. Board members feel that with the lines of authorities now established, the academic community is guaranteed a clearcut formal course through which, without going to the President, or the Director, they can intercede if they want to, and I think this is an issue that can't be brushed aside lightly.

Mr. VIVIAN. Has the power been exercised?

Dr. WIESNER. Under the present setup, the Board could go directly to the President or even directly to the Congress to complain about the operation of the Foundation. I don't know what the situation is with regard to the director, since he is appointed by the President and not by the Board. This is one of the problems that we were trying to resolve. I think any change must take into account the problem of providing a mechanism which is responsive to the desires and worries of the academic community. These are not just minor worries. One of the great dangers in modern society is increasing centralization, increasing control, and one ought to do everything you can to fight this consistent with the kind of evolution we want to see in our society.

Mr. VIVIAN. I don't dispute your concern, but I would like to shift to some other questions.

The relationship between the National Science Foundation and the Office of Education and the National Institutes of Health remains unclear to me.

The NIH has a very similar role and function, except that its concern is primarily in the biological area. It is not obvious to me why the two in some respects are not consolidated.

Likewise, the Office of Education has a relationship to both of these. However, I have no clear conception as to how these are related. Do you know?

Dr. WIESNER. I think I do, although I must say things change and I gather there is now a new coordinating committee for education that I know very little about.

First of all, the National Institutes of Health has no legal responsibility or authority for education. In fact, this is one of the flaws in the present arrangement. The NIH is not authorized to engage in educational activities, which is obviously very foolish, because whenever you support research in a university, you are engaging in an educational activity, but their mission is to support research in the health-related fields, and other groups have the responsibility for medical education.

I think this is something that one should examine. One can make a case for putting together the National Science Foundation and the National Institutes of Health and maybe one or two other organizations. This would have some advantages and it would also have some disadvantages because it would create a bigger bureaucracy. It in particular would create a situation in which there would be fewer independent supporting agencies, something that I don't happen to like.

The relationships between the NIH and the NSF have been extremely good through the years. Because the NIH is mission-oriented, its funding has been more generous than the NSF. The NSF has always been quite happy to see the NIH support those things that are health related and concentrate its support in other fields. To my knowledge, the degree of coordination between these two organizations has been good and they have worked together very well. It has the advantage that the NIH has invented organizational forms which were different from the NSF, so we have had experimentation that we wouldn't have had if we had only one group.

The problems of the relationship of both of these groups to the Office of Education is more complicated. The Science Foundation, one could claim, got into the educational business by default. If the Office of Education had been more aggressive, and with an interest in science, one might not have needed the NSF programs, but because it is much more closely related to science and science problems than the Office of Education has been, or I suspect ever will be, the Office of Education must deal with the full gamut of education including some enormous pieces such as the elementary and secondary schools. It is probably a good thing to have the NSF involved in science education too, providing that a high degree of coordination exists.

When I was the President's science adviser, we had an informal educational committee that included the Commissioner of Education, the Director of the National Science Foundation, the Chairman of the Atomic Energy Commission, the Director of the Bureau of the Budget, the Director of Research and Engineering in the Department of Defense, National Aeronautics and Space Administration, and several other agencies and myself which used to meet quite frequently to talk about the educational problems that involve all of these agencies.

I have the impression that this has been formalized into a new committee which the Commissioner of Education chairs, but I am not certain that this is precisely the origin of the present committee.

In any event, there have been continuing coordinating activities in this field.

In the field of educational research and development, there was and still is a panel sponsored jointly by the Commissioner of Education, the Director of the National Science Foundation, and the Office of Science and Technology, and this group has stimulated many of the activities which are now going on in educational research. As far as I know, this group will continue to function indefinitely.

One always gets into the debate about whether line organizations or coordinating efforts are better in a thing as big as the Federal Government, and I don't claim to know which is better, but I happen to prefer diversity.

Mr. VIVIAN. Mr. Chairman, I have a few more questions, but I think I can take them up later with Dr. Wiesner.

Mr. DADDARIO. Mr. Chairman.

Mr. MILLER. I am sorry I couldn't be here earlier for your testimony, Doctor, but the full committee is holding hearings on a subject that I think is close to your heart, the metric system.

I want to welcome you back and say that I am very happy that you are here.

Mr. DADDARIO. Dr. Wiesner, I want to thank you on behalf of the committee. If there is one reason for a better relationship between the Congress and the scientific community, and between the Congress and the executive branch, it is just because you played a great role in that regard. It is with ever-increasing regard for your participation in this process that I welcome you here and am pleased by what you had to say. It has been of outstanding value to this committee, Dr. Wiesner. I think that has been demonstrated by the remarks made by the members, and by their attendance this morning.

I would like also to ask if I might submit some other questions to you in some areas that we have not yet had an opportunity to cover this morning? [1]

Dr. WIESNER. Fine. Thank you very much.

Mr. DADDARIO. This committee will adjourn until tomorrow morning at 10 o'clock, at the same place.

(Whereupon, at 12:01 p.m., the subcommittee adjourned to reconvene at 10 a.m., on the following day.)

---

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

NATIONAL SCIENCE FOUNDATION

SEMINAR ON MANPOWER AND TRAINING

WEDNESDAY, AUGUST 4, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. DADDARIO. This meeting will come to order.

I am pleased to welcome on behalf of the committee a most distinguished group of men who have consented to come here today and discuss with the committee a problem of great importance to the country involving the proper utilization of our scientific and technical manpower. We plan to discuss what the present manpower situation is; what are the statistical problems involved, and what part the National Science Foundation plays in this scheme of things.

The committee is pleased to welcome this morning Dr. Leonard Lecht, Dr. Bryce Crawford, Dr. Bowen C. Dees, Mr. William Douglass, Dr. James Killian, Dr. Frederick Terman, and Dr. M. H. Trytten.

We will proceed alphabetically to hear the opening remarks of the panelists. However, Dr. Dees, who represents the National Science Foundation, will be the last to speak in order that he may first hear the comments of the other members.

We will, therefore, start with Dr. Bryce Crawford. We are anxious to hear from you, Dr. Crawford, and to the other gentlemen as well. Will you proceed, please.

STATEMENT OF DR. BRYCE CRAWFORD, DEAN, GRADUATE SCHOOL, UNIVERSITY OF MINNESOTA

Dr. CRAWFORD. Thank you, sir.

It is a pleasure to be here, and I am very happy to join in this seminar. We will be talking not only, we hope, to help the members of the committee; we are sure to learn from each other in our interaction on these particular problems.

I was not planning to address my initial comments to any of the statistical problems or the problems of the numbers of adequately trained scientific personnel we would need. The other members of the panel are far better equipped than I, I believe, to contribute that type

of information. As a matter of fact, speaking as the graduate dean of the University of Minnesota, I think it is generally known any attempt to get statistics on graduate school operations is one of the most difficult and woolly tasks in higher education, simply because of the great variety of the types of graduate students, the great variety of their degree of involvement in their graduate school activities, and the great variety of types of programs in graduate schools. I know that Dr. Trytten would agree with me on this fact.

I did think, however, that I might most usefully contribute some qualitative remarks on the subject of adequate training and how this can be done, and one particular aspect of the adequate training problem which involves me very deeply in my capacity in the graduate school at the University of Minnesota. This is the complex of problems: first that of recruiting graduate students, especially in the scientific and engineering fields, supporting them, giving them the best possible graduate school experience; against that we have the question of giving them research opportunities; against that we have the question of using these graduate students as teaching assistants and thereby aiding in the training of undergraduate students.

In very general ball park figures, at the University of Minnesota we have about 1,000 graduate students—out of the total of 7,000 I should remark—we have about 1,000 who hold teaching assistantships and therefore are taking part in the teaching enterprise. We have another roughly 1,000 students who hold research assistantships and derive financial support for their graduate study by, if you will, being paid to carry out their research studies. We have a smaller number, running to some 600 or 700, who receive support from so-called nonservice appointments. These are fellowships, some of them, naturally, National Science Foundation fellowships—from our viewpoint we wish there were more—some of them NSF traineeships, NASA traineeships, NIH fellowships, and various locally supported fellowships.

I would like to address a few remarks to the interaction of these three types of graduate student activity that I deliberately placed in opposition, and what I would like to do is to destroy that image of any opposition. I spoke of nonservice fellowships, I spoke of teaching assistantships, and I spoke of research assistantships. We sometimes hear a complaint that there are too many fellowships, that we don't need more fellowships. This is, I think, just numerically, a little hard to support. If you consider the fact that there are roughly a hundred thousand graduate students in the scientific and engineering fields, a little over that actually, and then you look at the total number of NSF fellowships, which is about 6,000, or even the total number of National Defense Education Act fellowships, which is some 7,500, you realize this is a small fraction of the total number of graduate students in these areas.

We also sometimes hear that research grants, research assistantships are pulling away good graduate students from the teaching enterprise, and this is sometimes viewed as a bad thing. The point I would like to make is that the graduate student enterprise partakes of the apprentice system. He gains his education not just by classroom

study and by listening to lectures but also very essentially by taking part in a research program. So the thought that research and education are somehow separable, or even worse opposed, is one that I think cannot be spoken against too often. The research assistantship in my opinion is just as useful a method of recruiting and helping to train graduate students as any other.

Also intertwined in this operation of graduate study is the teaching aspect, and it certainly is a valid proposition that serving as a teaching assistant, taking part in the education of undergraduate students, is of great benefit to the graduate student himself.

Here again, properly operated, we have an apprentice system which not only benefits the apprentice, but extends the range of operation of your master teacher, and it is, I think, an essential component of the total graduate school operation.

Ideally, I think we would like to have a system whereby all of these threads were intertwined and where any graduate student who carried out his research studies took some part in the teaching program, both for his benefit and for the improvement of our capacity to train well increasing numbers of undergraduate students; and also he should have an adequate amount of nonservice support at some point in his career so he can take an undistracted slice of time to devote to a concentrated endeavor in his own studies.

The National Science Foundation in particular and the various other programs which help us to recruit and support and encourage graduate students, have moved toward the concept of permitting their fellows to take part in the teaching enterprise.

My main point here is I wish they would go a little further in that direction. I would like to see an arrangement, which I am sure can be worked out, whereby fellows of all sorts, not merely NSF fellows, but all types, including our locally supported fellows, were not merely permitted to engage in the teaching enterprise but were expected to. I would not want to say mandated because individuals differ, and to make a requirement that every graduate student take part in active undergraduate teaching would certainly cause some individual cases of ineffectiveness.

I would like, Mr. Chairman, to let that be my initial contribution to the seminar.

Mr. DADDARIO. Thank you.

I would like to ask just one question. In your closing remarks you mentioned the idea that the teaching should be expected but not required. Do you mean to draw a line in those cases where a person may not be helped by the teaching role, and that in these cases the teaching requirement may be waived?

Dr. CRAWFORD. Yes, sir. I think you might with some slight exaggeration say that at present the initial assumption is that a fellow will not necessarily take part in any of the teaching enterprise, but he may. I would like to reverse that and say that the initial assumption is he will take part in the teaching enterprise, but in individual cases this would not be an absolute requirement.

Mr. DADDARIO. Thank you very much, Dr. Crawford.

Mr. Douglass.

STATEMENT OF WILLIAM A. DOUGLASS, PRESIDENT, CAREERS, INC.

Mr. DOUGLASS. Mr. Chairman, I can say initially it is very pleasant to be here.

I think my position in this field is somewhat different than the other members of the panel, in that they one way or another seem to be associated with the education process. Our company inherits these people after they have completed their education.

My company, for over 15 years now, has met some two and a half million college seniors as they go out into their first jobs. In the field of engineering and science we have systems which allow us to apparently meet them again and again as they develop in their careers. In other words, ours is an employment clearinghouse. The perspective is different in that we are working on employers' problems. I might point out that the problems here are those of Government agencies as well as of private firms.

My invitation to appear here today with this panel and before the distinguished members of this committee is both a pleasure to me and a warning. The pleasure is derived from the too infrequent opportunity I am provided here to step back a little bit from day-to-day involvement in manpower subjects and to join you people in thinking about some of these subjects. The warning is the challenge that such opportunities present to us all, and that is that we really have something significant to say and hopefully something significant will come of what we have said.

Let me illustrate this warning. I think it is a very real one. In September of 1963 I invited to New York a panel of manpower experts to discuss the proposition "Engineering—a Profession in Trouble?"—with a question mark on it. We printed a transcript of that debate and received wide circulation. This May of 1965, under the auspices of the IEEE, I again set up a panel on the same subject. As a part of the press notice to many technical publications there was included a transcript of the first panel of 1963. You can imagine my surprise yesterday when I picked up the July 1965 issue of one of the technical publications that had received this release and found that the 1963 transcript had been interpreted by them to be the 1965 discussion. I read the 1963 transcript in haste with potential horror to see if we had dated things, because there was the big dip in engineering needs in late 1963. I didn't see anything in that which they reprinted which couldn't be said again today and still be the problem it was then. But that is only a 2-year-old study.

I was down here before this same committee in 1959 on very much the same subjects that we are hitting today. I gave what I believe was significant testimony because it pertained to the utilization of technical manpower, and I said, with a feeling of guilt then, as I do now, that if some 60,000 engineers and scientists applied to my concern for change of job in the last 2 or 3 years, there is certainly something going on in the field that at least needs to be discussed.

I say significant, because the committee itself had sufficient interest to hold additional hearings on the subjects which I proposed, and they even wrote a bill. The bill is very much to the heart of our discussions here today, I think, because it proposed congressional funding of a program for far better manpower statistics than any of us possess.

I re-read those hearings this past weekend and quite honestly, if you threw away the dateline, I think much of it could be equally cogent today.

I realize that my 6-year study can be topped by all other members of the panel because I am sure that most of you could cite things that were said 20 years ago, problems which you identified then which are still problems now. I wonder if you are satisfied that having identified these problems, enough has been done to research whether they really exist or not, and if they do exist whether enough has been done to face them and perhaps try to solve them. Demonstration projects, I think, are at least a timid way to try and find out answers to problems. The worst you can do is find out you are wrong.

So you can perhaps sense better than I both my privilege and my urgency in being here. Panels like us can touch on so many fascinating subjects—technical obsolescence, continuing education not only for the successful [the Sloan Foundation fellowships I think at MIT are a great step toward taking people who are past 35 years of age and giving them a reeducation. But I wonder if this can't always be done also with some of the unsuccessful, those who are technically obsolescent, those who have educations which are no longer applicable to the engineering needs of today] graduate study, mobility, the proper use of skilled aliens. [The last is something that hits us very hard as we get many alien engineers and scientists. They are virtually useless to all of our companies who are in any way engaged in the security business. I think that the aliens themselves wonder sometimes how Dr. Von Braun ever got in here, because somehow or other we cleared him and we can't clear these fellows.]

But I felt in 1959 and I feel today that each of these subjects we could talk about is going to be somewhat inconclusive until we have gone a great deal deeper in our knowledge of the problems behind these subjects, manpower research, and until we have done a great deal more to try to create solutions to these problems than we have today.

I thank you very much.

Mr. DADDARIO. Thank you, Mr. Douglass.

Our next participant is Dr. James Killian, who is the chairman of the Corporation of the Massachusetts Institute of Technology. Dr. Killian has worked with this committee and with the Congress and the executive branch for many years. He was the first science adviser to the President, and holds a unique position in the eyes of the entire scientific community.

We are anxious to hear you, Dr. Killian.

STATEMENT OF DR. JAMES KILLIAN, CHAIRMAN OF THE CORPORATION OF THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY

Dr. KILLIAN. Thank you, Mr. Chairman, and gentlemen. It is a privilege to be here.

I would like to mention several somewhat different topics as possible pegs on which we might hang some discussion later on.

First of all, I would sum up my view of the supply-and-demand situation of scientists and engineers by saying that in the years ahead shortages are more likely to occur in science, engineering, medicine, and mathematics than in the humanities, the social sciences, and law.

This continuing demand for increasing numbers of high-quality professional people seems to me to be a prime factor in planning the future of the National Science Foundation.

Recently I chaired a committee of the National Academy of Sciences which reported to the President on the utilization of scientists and engineers. This report concluded that contrary to many public statements we run the risk of having too few rather than having too many students elect to study science and engineering. And the report also noted that the percentage of our college population committed to science and engineering has been such that these fields are not robbing the humanities or other fields at the present time as we sometimes hear.

This whole business of projecting demand and supply is a very tricky one, but this is a way that I would sum up my present judgment.

The next topic that I would mention is this one that has been touched upon by Mr. Douglass, the problem of having adequate information.

There have been a number of study groups, both within and without Government, that have repeatedly recommended giving a single agency or office in Government specific responsibility and authority for coordinating the various efforts of Federal agencies to provide an adequate and continuing body of information on scientific and technical manpower.

The Select Committee on Government Research made this recommendation, the National Academy Committee made this recommendation, and there have been others.

To the best of my knowledge this has not been achieved. The responsibility, of course, probably vests, as I understand it, in the President's Committee on Manpower at the present time, and probably there have been a matter of priorities there. Currently the National Science Foundation and other Government agencies are collecting great amounts of data on manpower, but there is yet no central place where it can be brought together and expertly made useful to decisionmakers. We need more interpretation of this data and more projections, taking into consideration future alternatives that may affect the situation.

While I do not suggest specifically that the National Science Foundation assume this function, as a major source of information, a very effective source, it must have a partnership participation in such a central effort. Above all, we need a single office in Government charged with the responsibility for keeping under continuous review the supply and demand of science and engineering manpower, and with the responsibility to present it in a form that will facilitate action and decision.

My third topic is to remark that looking back on the Foundation's history I would conclude that the most important thing that the Foundation might have done that it did not do was to initiate much earlier its program for aiding potential centers of excellence and creating new innovative programs.

I hasten to say that this failure should not be charged to the National Science Foundation because I think all of us in the community of science and engineering and the educational community failed to appreciate the importance of getting started on such a program early enough. It takes a long time to build these centers and to achieve

for them the right tone and atmosphere as well as the necessary resources.

We need additional centers of strength now. We will need them more in the future. So far we have been too dependent on a few centers where graduate students can be trained in an environment of excitement and excellence. While it is unquestionably desirable to achieve a geographical distribution of such centers, it seems to me that the overriding objective, and this is a view that you have certainly heard, should be to gain some increase now in the number of centers where first-rate talent can receive first-rate training.

The present centers of strength cannot turn out enough high-quality graduates to meet the growing national need, at least they cannot without growing too big. These additional centers must be aided without penalizing the present ones, and we must be realistic in realizing that only a small number can be created within the immediate years ahead. The limiting factor, of course, is faculty.

My final statement is to remark that the Foundation has made a breakthrough in the improvement of American education by the support it has given to curriculum development and teacher training. This has been to me one of the most impressive accomplishments in American education in the last several decades. There is still, however, a big and urgent job to do, and the Foundation's program in my judgment should be expanded to support more work in curriculum development, curriculum reform, and teacher training in the field of the sciences. When a breakthrough of this kind occurs, we should not fail to explore it fully.

There are a number of other topics that might be touched upon that seem to me to be important in the manpower picture, but I will rest with mentioning these specific topics at the present time.

Mr. DADDARIO. Thank you, Dr. Killian.

Dr. Leonard A. Lecht, Director of the National Goals Project, National Planning Association, is our next participant.

STATEMENT OF DR. LEONARD A. LECHT, DIRECTOR OF THE NATIONAL GOALS PROJECT, NATIONAL PLANNING ASSOCIATION

Dr. LECHT. It is a pleasure to participate in the work of the committee. What I have to say I say as an individual and my views are not necessarily those of the National Planning Association.

It is interesting to note that between 1953 and 1963 spending for R. & D. roughly tripled in the United States. Most of this increase has been the result of public spending in pursuit of national objectives in three areas—defense, space, and atomic energy. These three areas together accounted for about seven-eighths of all public R. & D. spending in fiscal 1962 and 1963.

The National Planning Association has attempted to estimate the dollar cost of pursuing national objectives in the 1970's. R. & D., of course, ranks as one of these objectives, along with improving health and education or rebuilding our cities and our transportation system.

We estimate that the pursuit of national objectives would involve R. & D. spending in 1962 dollars amounting to $39 billion by 1975. This means an anticipated increase in R. & D. spending of almost two and a half times between 1962 and 1975, from $16 to $39 billion.

In terms of GNP, R. & D. expenditures are projected in our estimates to increase from 3 percent of GNP in 1962 and 1963 to 4 percent of the trillion-dollar GNP anticipated in 1975. And while spending for R. & D. related to defense, space, or atomic energy is expected to continue increasing over the next decade, the largest percentage increases are listed in what we might call the civilian economy area in health, in transportation, in the many industries conducting little research, and in coping with such problems as air pollution or the need to increase the Nation's and the world's supply of usable fresh water.

About a year and a half ago the Committee on Utilization of Scientific and Engineering Manpower asked us to translate our estimates of the dollar expenditures for national objectives into estimates of the scientific and engineering manpower requirements they implied in the 1970's. We are currently preparing similar estimates as part of a study of manpower requirements for national objectives we are conducting for the Office of Manpower, Automation and Training of the Department of Labor.

Our projections for the Committee indicates that achieving the Nation's objectives would involve a 125-percent increase in the number of scientists and engineers in 1975 over the 1960 level. Allowing for the replacement of losses due to normal attrition, this works out to an anticipated increase in the pool of scientists and engineers of 1¾ million between 1962 and 1975. The largest percentage increases are listed for education and for the space program, with the absolute increase in education being far greater, of course, than for space.

Like all projections these estimates are speculative since they continue recent tendencies and expectations into an unknown future. Yet the underlying tendencies the projections reflect have significant implications for national science policy, for education policy, and in other areas.

One of these implications is the need for national planning to take into account the impact of national priorities on the supply and demand of technical manpower in policy decisions. This kind of planning would identify the scientific and engineering skills which will be required for all our major national activities, public and private, and it would do so on a continuing basis. It would also involve projecting these needs several years ahead and delineating the magnitude and timing of the technical manpower requirements before they arise. This type of planning could be part of an overall mechanism for program appraisal established in the Executive Office of the President.

If we are to produce the numbers of scientists and engineers the nation is likely to need in the next decade, a balance must be struck between the supply of scientists and engineers added to the manpower pool by the educational system and the demands for additional manpower from the pool.

Since the demands for manpower for college and university faculties, for national security R. & D. or for civilian economy R. & D. are competing demands at any particular time, an allocation balance must also be struck if all of the competing demands are to be served.

Until about a decade ago these balances were largely determined by the market. While the market is still a significant factor, the great change in the past decade has been the far greater role of public

policy in influencing the demand side of the balances, and more recently, and probably to a lesser extent, in influencing the supply side.

Devising public policies to achieve satisfactory balances in these areas would involve the kind of planning we have mentioned. For intelligent planning, in turn, we need far more research to improve our understanding of the factors that influence the demands for technical manpower and, even more so, the supply.

The information at our disposal has been growing. The work of the National Science Foundation, the work of the National Register of Scientific and Technical Personnel, and surveys of the Department of Labor have given us a good bit of basic source material and of factual data. While we have much more and better information than we had five or ten years ago, the gaps in our understanding are still of considerable significance.

To cite one example, since the late fifties, the percentage of all bachelor's degrees accounted for by bachelor's degrees in engineering has been consistently declining. This percentage has fallen from 10 percent of bachelor's degrees in 1958–59 to 7½ percent of all bachelor's degrees in 1962–63. Yet we don't really know why this decline has taken place since we know too little about the determinants of occupational choice in our society.

Or, the possibilities for achieving large-scale increases in "civilian economy" R. & D. will be significantly affected by the degree of convertibility of technical manpower with experience in defense and space R. & D. to R. & D. in such areas as mass transportation or pollution control. It is also likely to be affected by the convertibility of the techniques, such as operations research, which have been so extensively developed in the defense or space programs.

To date we have few studies of the experience of scientists and engineers who have moved from one of these areas to another, or studies of the experience of firms with substantial research capabilities which have attempted to use part of these capabilities in the new and growing areas of civilian economy research.

To summarize, our Nation will need more trained and educated manpower in many fields in the next decade, including many more scientists and engineers. The prospects of success in increasing the supply of technical manpower and utilizing it effectively would be substantially improved by taking positive steps to develop and expand manpower research and planning as a basis for policy.

Mr. Daddario. We will hear now Dr. Frederick Terman, vice president of Stanford University.

STATEMENT OF DR. FREDERICK TERMAN, VICE PRESIDENT, STANFORD UNIVERSITY

Dr. Terman. Mr. Chairman, members of the committee, trained manpower, particularly manpower trained in the sciences and engineering, represents what is probably the most important natural resource that this country possesses. In science and engineering particularly, trained manpower is the basis of the technological development that makes the U.S. economy so distinctive and which underlies both our high standards of living and our military security.

Now I am going to direct the rest of my remarks primarily to the engineering, mathematical, and physical science area, passing over the health field, which is handled separately, and I think is really in much better shape from the point of view of the needs of our country than is the case with the physical sciences and the mathematical sciences and engineering.

During the last 15 or 10 years there have been a whole succession of waves of concern regarding the shortage of engineers and scientists in this country, particularly the shortage of engineers. My feeling, however, is that much of this concern has been misdirected into a concern about numbers, sort of a head count, vis-a-vis the Russian numbers in relationship to our numbers.

The few studies that have been made, in at least my own qualitative judgment and that of some of the people I have worked with, such as the Gilliland Panel on Manpower, are pretty much in agreement that we have never really suffered from a critical lack of warm bodies stamped with the B.S. label, but we do now have, and we have continuously for at least 25 years had, a continuing shortage of engineers and scientists who lack higher levels of training that are really needed—higher levels of training combined with high ability. There is a real shortage and a continuing shortage in that category of people. This is particularly true in the mathematical sciences and engineering where something like 6 percent and 4 percent, respectively, or about 1 in 15 or 1 in 25, of the bachelor's degrees go on to complete work for the doctorate degree. The situation is better in physics and chemistry where about 15 and 20 percent of the bachelor degree people do ultimately receive the doctor's degree. That means something like 1 in 5 or 6.

Now for those capable of leadership and of making significant contributions in our technological world as it exists now, a 4-year college course ending in a bachelor's degree is simply no longer adequate for a career in engineering or science, at least not a career that makes full use of the abilities of the more capable people.

At present far too high a proportion of our outstanding young people in these areas, and particularly in engineering and science, discontinue their formal training before they have obtained all of education that would benefit them and enable them to maximize their contribution to society. As a result, today's manpower pool in technology and science is a good deal more adequate in quantity than it is in quality as far as meeting our needs is concerned.

All too often employers, and this is not just defense employers, but employers either for civilian or the defense or space needs, will settle for a man with a bachelor's degree training in filling a billet when what they really wanted and needed was a man with a master's degree training, and they will settle for a master's degree training—they are forced to settle for a master's degree training, when what they really needed and know they need is a man with a doctor's level of training. These people with the higher degrees are just simply not available in the numbers in which they could be absorbed usefully.

This situation downgrades the effectiveness of our industrial economy, and it weakens our space and weapons program. As a result of quality of personnel that is inadequate to do the job, projects—this is not just military projects but all projects—will tend to take

longer to complete than they should, and this, of course, means they tend to overrun their costs. When personnel is of inadequate quality, projects often fall substantially short of achieving their desired objectives, and sometimes get canceled because the problems that are involved don't get solved, or drag out so long as to lose timeliness.

In both the civilian and Government programs involving newer fronts of technology, the difference between success and failure or between a rapid development and one that drags out so long that its real usefulness vanish is determined by the success in solving the more difficult problems involved, and here the quality of the people that are working on those problems is all important. The lack of high-level ability combined with adequate training to utilize that ability cannot be compensated for by simply putting more people on the job.

This competition—and incidentally it is an international competition, broader than just the military arms race with Russia; the quality of manpower is as important in this area of international technological competition as in an international track meet. How many people does our Nation need on our team who can run a mile in 5 minutes, just hundreds if you want, to equal three or four that can do a 4-minute mile for the other side?

For these reasons, because of what I regard as a very critical need for more able people going on for higher level training, I am particularly pleased at the steps that have been taken in the last couple of years toward implementation of the report *Meeting Manpower Needs* that came out from the President's Science Advisory Committee in late 1962. These steps have included the development of a new training grant program by the National Science Foundation, a substantial expansion in the NASA trainee program, and further enlargement of the NDEA title IV actvity. At the same time I am somewhat unhappy over the fact that what we have been doing is not enough and falls below the minimum targets that were set up in 1962 by the PSAC, and particularly the targets that were set up then for engineering and the mathematical sciences.

The Nation's economy needs more able students in the engineering, mathematical and physical science areas going on for graduate work. The present bottleneck in achieving that result is lack of support for students. We have to recognize that in our present society, virtually all of the students that do graduate work in these areas expect to receive a substantial degree of financial support, of the order of tuitions and fees, plus some very austere living standard, and if they don't have that they just don't go on for graduate work.

Those of us who have worked in universities trying to develop enrollment in graduate programs find this is one of the essential facts of life. No matter how good your faculty is, no matter how attractive your activities are, if there isn't the student support, you don't get students—you don't even get bad ones.

We just need more support for people who are going on and who are qualified to work for the master's and doctor's degrees.

The fact is the National Science Foundation is spending a good deal more—I think I am right in this—upgrading high school mathematics and science teachers, than they are spending on producing new scientists and engineers with advanced training in order to be teachers and in order to serve our industrial and Government needs. I am not

objecting to the money that is going for this high school science program. It is certainly money well spent. But, on the other hand, we have another need that perhaps, if anything, is more important because it is on the cutting edge of where things affect the gross national product and our military security, and this is really being neglected in comparison. This Nation needs to invest more than it is presently investing in graduate work in the mathematical, engineering, and the physical sciences, and, particularly, in engineering and mathematics. I use the term "invest" advisedly in this connection, because money spent in giving students better training in science and technological fields relating to the needs of industries and the weapon and space programs will over the years bring a very handsome return of many kinds to our society.

This $39 billion a year expenditure for R. & L. we have just heard about by 1975, will produce more for our money, or it isn't going to cost as much to get the job done if we have better trained people working in this program. These benefits include economic returns, higher standards of living, and increased military security. One might say in a philosophical sense, transcending all of these is also the fact that better training for able people makes a contribution of the first magnitude to the quality and the humanity of our civilization.

Thank you.

Mr. DADDARIO. Thank you, Dr. Terman.

Our next participant is Dr. M. H. Trytten, Office of Scientific Personnel, National Academy of Sciences.

Dr. Trytten, we are pleased to have you here.

STATEMENT OF DR. M. H. TRYTTEN, OFFICE OF SCIENTIFIC PERSONNEL, NATIONAL ACADEMY OF SCIENCES

Dr. TRYTTEN. Coming at the end of the line here—we are well aware that Dr. Dees is coming along, but of those preceding him I come at the end of the line, and this has both its advantages and disadvantages. Sometimes you find that your speech is all shot out from under you in cases like that, and in other cases it gives you the advantage that you can potshot at what other people have said.

In my own case, I would like to make two rather brief points because the time is moving along.

The first of these relates to a thread that I think has gone through the comments here in the case of several people with regard to the need for more study in depth of the various manpower problems that we have been talking about. I suppose one might call this sort of a basic research as applied to some of the others. Our concern over the past few years has focused a good deal on getting information, factual information, and I for one would certainly like to pay tribute to the National Science Foundation for a marvelous job—marvelous improvement in the extent to which we have information on manpower in this country—but I also know in doing that, in establishing a series of that kind, one creates a tyrannical situation. These recurring series are tyrants. They determine what people are going to do today, and the next day there are deadlines all over the place, even to the extent of determining what you are going to do on the 3d of July 1966, and so on. It doesn't leave much opportunity for this kind of concern

in depth for what these statistics mean, a study of the problems in depth. It is this, I think, in which Dr. Wolfle was driving at in his testimony here about a month ago to this committee when he spoke of the need for a group or an entity, perhaps—I think he used the word "agency," I would prefer to use the words "some kind of entity" for this kind of research—of a very contemplative, analytical nature to determine the meaning and significance and completeness and relationship of all the factual information we are getting, together with factual information on the needs of society. Dr. Wolfle mentioned one such agency which has been established, and of which he is now serving as a chairman, the Commission on Human Resources. This is an outgrowth or, rather, a reestablishment of the same kind of an agency back about 15 years ago, on which he served in such a distinguished manner, and whose report was, I think, a genuine milestone in this whole area. It was the opinion that something like this was needed again that led to the reestablishment of this kind of commission.

The thing I would like to comment on, since we are talking about the NSF, is the problem of support for that kind of an agency. It is financed at the moment with private funds, and the experience of the agency, I think, is an indication of the kind of problem we have here in supporting this kind of an agency. It has what seems like a fairly generous support from two of the foundations. Nevertheless, this kind of work is expensive, and the grant itself establishes a terminal point. What is done must be done between two specific dates of fairly short duration.

About 2 years, in fact, remain during which these studies are to be carried out. I think it is obvious that this information shortens the focus that can be established for this kind of study.

There has been no thought given yet of any practical nature to finding support elsewhere. But it seems to me entirely reasonable to ask whether a perfectly satisfactory agency, such as the NSF, or indeed other agencies, should not use this kind of situation to get some of this done, to support this kind of research. I have a feeling that this kind of research should be done outside the Federal Government. I think this is a debatable point, but my feeling is that it is more likely to be done outside of the Federal Government. And I also think it is dealing with matters which are significant, which are sensitive, if you wish, with respect to the nature of our private activities in this country in training and indeed in the utilization of scientists. So I have a feeling that it is more proper to be outside than inside the Federal Government.

However, as I say, this is entirely debatable, and this is not to suggest a particular approach for this particular agency at this particular time, but merely to point to it as an example of the kind of problem that I think applies when we talk about getting this kind of research done in this country.

I would like to mention one other point, which goes back to what has been said around the table here with respect to traineeships, fellowship programs, and so on. There is, I think, a very real question which has been alluded to by one or two of the speakers as to where the most lucrative target is, if one does indeed want to expand the production of scientists and engineers, as Dr. Terman feels, and I

think the rest of us feel, is very important to do. One notes, for example, the percentage of students in the freshman year in the science fields, and for the moment let's leave out engineering, which according to Dr. Lecht is decreasing in percentage, in these other areas it remains about the same, and partly this is due to the fact that mathematics has actually increased a bit. The flow into the graduate school, however, because of the increasing amount of support, has gone up quite a bit. Much of this has been by the invention of new types of fellowships, such as traineeships, and the National Defense Education Act fellowships, and so on, in which we have, I think, inadequate information as to the quality factor. We know a good deal about the quantity, the numbers that are supported by the program, but we don't know enough about how these people compare with other people on other programs with respect to how good they are. I don't mean to say that I have any suspicion that the quality is going down or up or anywhere else, but I am trying to say that I think it is a part of prudence to try to build into these programs some ongoing measure in which we will know the kind of people we are supporting.

I think that is all, Mr. Chairman.

Mr. DADDARIO. Could you expand on that last statement just a bit. What do you mean when you say it is prudent to build a quality factor into the program?

Dr. TRYTTEN. I would not suggest that you build in any quality measures that would be used as a basis for the selection of the individuals. This is not what I had in mind so much. One turns to the institutions, themselves, and asks them to make the selection. But it would seem to me perfectly proper to request some sort of postaudit as to quality. Take some kind of test during the course of the year, perhaps a graduate records examination, or whatever it might be, so that sometime before the end of the first year's period, and possibly reflecting whether the individual has continued, or not, there be this kind of measure which is on the record, and which is reported to the donating agency.

Dr. TERMAN. May I make an additional observation on that point: I have been pressuring our own people at Stanford on the National Defense Education Act program to make an initial audit on this because we have a large Ph. D.-producing program independent of National Defense Education Act, but we have worked in National Defense Education Act people. We would like to see how well our own departments of the university have handled these Government programs in relationship to others. I think for our own self-discipline this is good. If there was some outside pressure to get an audit, also, I think this would be even better, because it would help me to get the material that I think we need for our evaluation purposes.

Dr. CRAWFORD. I agree with Dr. Terman and Dr. Trytten that this business of keeping an audit of how well you are doing is desirable. An initial audit is fine, but the use of some general applicable, well-established testing instrument is also important.

Dr. Trytten mentioned the Graduate Record Examination, and I think it is safe to say that this particular tool or testing instrument, like most of the instruments, could stand a great deal of improvement, and needs it quite badly. One element perhaps in the improvement of this

depth study of manpower, one necessary element in providing this post audit or this keeping tab, is the getting underway of a study to improve, normalize, and really evaluate such things as the Graduate Record Examination.

Dr. TRYTTEN. I would want to say amen to that.

Dr. TERMAN. I agree this would be very helpful, but I do not think we have to wait until it gets done, because we have pilot groups that are representing the people who are going through with other forms of support of the traditional type, and we can use these groups at least as some sort of standard of comparison in the meantime. So let's get on with it.

Dr. CRAWFORD. Let's get on with it, but let us sharpen the tools as we proceed.

Dr. KILLIAN. This is something that the universities have got to take the responsibility for doing, it seems to me. Any kind of national effort to impose any kind of a test here may well be a boobytrap.

Dr. TRYTTEN. This is why I said not before the selection. I think that would deny the nature of the traineeship selection program. But afterward is a different matter.

Mr. DADDARIO. Do you have further comment on that, Dr. Crawford?

Dr. CRAWFORD. No.

Mr. DADDARIO. Dr. Killian, how would you get the university to do it? I quite agree that they should, but they already have the opportunity and have not done so.

Dr. KILLIAN. I am not so sure that they are not steadily increasing their standards for graduate study. In fact, I think there has been a marked elevation of these standards in the last 5 years in this country.

I would make this general comment which has a bearing on the allocation of NSF efforts and funds. It seems to me in the long run one of our problems here is to have a pool of talent that would be sufficiently large and sufficiently good so that the graduate schools can make a better selection than they have been able to make so far. This brings me back to the point I made in my own remarks that I think the whole question of science preparation in the precollege schools, and the improvement of curriculums at the undergraduate level, is of fundamental importance in getting the kind of graduate students that we need in this country. Therefore we need very much to stress this part of the program as a long-term effort. If we delay and defer the improvement of teaching in science, we are going to delay the increase in quality at the graduate school level. I also think the better teaching of science at both the precollege school level and the undergraduate level is going to attract more first-rate students in this field in competition with other fields, and we need to do this now.

Dr. CRAWFORD. To attract more and better students into the teaching of science?

Dr. KILLIAN. That is right.

Mr. DOUGLASS. If I could just add an additional second to these points, which I feel so strongly about. We talk each year about the numbers of engineers that graduate, and no one faces the fact that these people are just like everybody else. A lot of them aren't very good engineers. A lot of salesmen are not good salesmen. The as-

sumption that the figures tell the full story is absolutely false. We have people who have tried to imply that somehow people who have come into our files must be men who are restless, they must be second rate somehow. This is not true. We have our fair share of Ph. D.'s, we have our fair share of masters, and so forth. I would say 90 percent of these people are unsuccessful through us in the average job hunt, and yet we put them right now against the needs of some 70 employers, the big ones right across the country. The ones with needs yesterday for 2,000, 4,000 engineers and scientists. And yet with these fabulous needs, the company with the size of Boeing or Douglas, taking a look at 600 engineers we brought into New York City several weeks ago, the company bids a top of 100 for interview, and maybe settles for 10. So the screening is harsh.

When they get out of college this is when their chance is best. As they get older, the world gets much more harsh. By the time they are 35, the world is hard; indeed, you cannot speak about engineers at 35 or over in terms of quantity because the quality factors become determinant.

Mr. DADDARIO. Was this what you had in mind when you referred to the possibility of retraining these men over a period of time to meet the rising needs within the community?

Mr. DOUGLASS. Yes. We have wondered, sir, how one can talk about shortages when there seems to be every year—even at the peak of the manpower rush in 1962, when NASA was out recruiting everywhere, the shortage was great, yet this same factor that I have talked about has been true, a tremendous waste of people.

Three years ago I met Dr. Pickering and Mr. Miller at a Rocket Society show in Los Angeles and we talked by an exhibit there just briefly, and I will never forget it because Dr. Pickering said he thought that perhaps 25 percent of the people they turned down at the Jet Propulsion Laboratory could probably be useful to the Jet Propulsion Laboratory with as little as 3 to 6 months of training in things that they lack. They were all right as people, nothing wrong with them as people, hirable, but on the other hand the Government doesn't underwrite education in advance of employment. So they turn them down because they are under pressure, as is every defense contractor, to do things yesterday, and they cannot afford training schools in advance of employment. Yet there is this very frustrating factor of the power engineer, for example. We had a study 2 or 3 years ago, it is again not a very deep study, but we were curious why all these people were being turned down by the glamorous companies of today; 89 percent of industrial engineers, 91 percent of civil engineers, 94 percent, I think it was, of the power engineers, the pre-1948 engineers. You can say it is an age factor, but they just don't know the right things for industry today. There is a problem here.

I think industry itself contributes to it. I was down here with the Gilliland Panel a couple of years ago, and we had the Bell Labs people here, and they told us of their fabulous continuing educational programs. The only thing they didn't really get down to, nor does anybody like that, is that this continuing education has up to now pretty well ceased at about the year of 35. The first 10 years you can go get your master's and your Ph. D. and get pay increments in the

better companies; but around 35 years of age the faucet is turned off, and technical obsolescence continues.

Dr. KILLIAN. Mr. Chairman, this just seems to me to support in the most eloquent sort of way the importance of better science education, better fundamental education, better engineering education that gets at the fundamentals. It gets rid of obsolescence, as it represents a concerted effort to be innovative and to be advanced enough and up to date. I think this is one of the major matters that we have in this whole matter of quality in graduate study at the present time.

Dr. TERMAN. To second that, but in a slightly different way, the student who goes on for a master's degree has a much better base from which to work when shifting from one area of emphasis to another as times change, and the fellow who goes on and gets a doctor's degree has even greater flexibility available to him in his career. He has learned enough different things so that he can move into new areas effectively. This is one of the very important social values of graduate education, i.e., these people can learn by themselves much better than if they have only a 4-year training.

Mr. DADDARIO. It gets back to Dr. Killian's point that if you have the solid training all the way down the line, the opportunity for obsolescence becomes less.

Dr. TERMAN. The opportunity for the person to self-remedy his deficiency is very much greater.

Mr. CONABLE. Looking at this in a little broader sense, one of the great problems of living in our society is to stay really alive, and this applies to lawyers, this applies to doctors, this applies to Congressmen. It certainly is not a peculiar problem to scientists.

I take it that you gentlemen are suggesting that with respect to science, the Government perhaps has a role that goes beyond the individual's responsibility to take care of himself. The Government has an obligation, for instance, to see to it that a man keeps himself trained in modern terms, that he keeps moving ahead in an individual sense because of his social utility, that his cutting edge does not become dulled by the processes of obsolescence.

Now, am I going too far?

Dr. TERMAN. No.

Dr. KILLIAN. May I respond to this? I would not say the Government has a responsibility to this individual man to keep him up to date. I would say that in the planning of a program for the support of education and for the support of science, it is of enormous importance that we recognize that the rate of change in the field of science and technology is so great that we have a special problem and ought to provide opportunities first of all to train people more fundamentally so that they are more versatile, and adaptable to change, and, second, to recognize that there is a problem of additional graduate study to give this higher degree of adaptability, and even a postdoctoral study, and further a postdegree education, a continuing education, which is steadily becoming an increasingly total part of our system.

Dr. CRAWFORD. I think there is an important element here when we talk about the need for retraining; the very important point that Dr. Killian made, that if a man has sufficient basic science in his original training, if he has really mastered, so to speak, Maxwell's equations

and not just network theory, then new developments in science are easier for him to keep up with. I think that is perhaps the most important point that comes out of this. I think that when we hear about these large numbers of engineers over 35 who are in need of retraining, what we are really seeing is a backlog from the period in which most of the practitioners in engineering and science had not received proper advanced work, when as some of the figures that have previously been cited show, most people took a B.S. and went out in industry.

As to whether or not the Government has an obligation to the individual, or not, I do not think it has an obligation to the individual unless you need that individual's potential contribution.

Mr. CONABLE. For a social purpose?

Dr. CRAWFORD. For a social purpose.

Mr. DADDARIO. Mr. Conable has raised the point that not only scientists become obsolescent, but also Congressmen. We have a member of this committee who is both a scientist and a Congressman.

Mr. Vivian, would you care to comment?

Mr. VIVIAN. I am afraid, as a scientist, I have become very obsolescent by now.

I have a question on a somewhat broader scope than the comments so far.

Most of my friends and colleagues in the scientific professions at about age 35 when their families have formed, realize that life has two ends, really an end and a beginning. They begin to make different decisions than they made before, and it is a time when they realize that their background training is not very satisfactory. In a sense it is the time for another new career for them. Again, around age 55 a great many men realize that what they have hoped for in life, and what life really offers, have become somewhat separated. For some it is a time to plan what other job they can get, if they can get a job at all. It is another critical stage.

I would also point out that a number of industries in my area are now giving retirement training courses at about that age bracket, and these courses have been very, very happily accepted. They are apparently one of the few things that everyone involved seems to agree is beneficial. I refer now to the company, the universities which are backing them, and I think very wisely, and the individuals.

I would like now to drop back to another critical age, that is, about age 15. This is the time in high school when a competence in individual careers is beginning to be formed for a person who does not go beyond high school, who does not enter college training. We give our entire population between ages 15 and 18 a free education to meet the needs of the age span from, say, 18 to 35. We pay for the education out of public funds as a worthwhile investment.

I propose now that we consider the following: From age 35 to 38 we give free public education to everyone who wishes it, including some provision for family support for a period of 3 years. This is a retraining phase in whatever occupation a person may select. From age 55 to 58 we do exactly the same thing, and we drop this sacred cow that one can be trained at public expense only up to age 18. I suggest this for consideration by the panel.

Mr. DADDARIO. Mr. Douglass?

Mr. DOUGLASS. I think this point is germane——

Mr. DADDARIO. I am not asking you necessarily to reply.

Mr. DOUGLASS. That is all right. I wanted to take Mr. Conable's observation first. They are both in the same area.

The Government certainly doesn't want to get obligated for everything that it is not already obligated for. It is probably obligated enough.

On this question of retraining, I think it is worth while to remind you all, and for us to remind each other, that the Government is paying the bill on the major part of this problem anyway. If Dr. Pickering is right, the retraining cost would probably be less than hiring an engineer from somewhere else.

Mr. DADDARIO. Or cancel a program because we do not have the people to do it.

Mr. DOUGLASS. That is right. I think it is very important to remember that the bill is probably being paid in 80 percent of the cases by the Government, so inefficiency in scientific and engineering manpower is a Government bill.

The question is not whether or not the Government should be responsible in this area. We are a little bit past that, as long as the Government is as heavily in research and development.

As to retraining at 30 or 33 or 35 I might throw out how simple we thought this might be effectual. This was just a quick suggestion at an exhibit at a show. The idea was maybe that there could be sort of a review board at Pasadena and JPL would meet this man and say "This man is hireable to us. We would like his record. We see the things he doesn't have that maybe he needs here". And they would send him with a little ticket down to a review board, so to speak, and this review board would say "Yes, indeed, you can get these courses in the Los Angeles area." After he had successfully completed these courses he would report back to JPL. In this area there are many problems. That sounds very simple, but it is still perhaps an approach. It is the type of thing that I mentioned much earlier, the possibility of demonstration projects to at least find out if some of these things lead to solutions to problems that have existed for years.

Mr. DADDARIO. Dr. Dees?

STATEMENT OF DR. BOWEN C. DEES, NATIONAL SCIENCE FOUNDATION

Dr. DEES. Mr. Chairman, at some point I would like to have a chance to make some comments. I am not terribly sure this is the point at which I should come in. I did, however, want to pick up this last comment with respect to demonstration projects of various kinds. Perhaps I could start off by saying that NSF has in fact in this and many other areas attempted to try out this, that, or the other way of coming at some of these problems.

It is perfectly true, I think, that one can say in this as in most other areas, that all we really need in order to do most of the things that have been recommended here today is more money. The fact of the matter is you cannot do these things without the dollars to back the play.

I would like, if I may, Mr. Chairman, to go back a bit and pick up some of these things because it does turn out that on the review of what I have been hearing this morning there are a number of points that NSF does necessarily get involved in, in one way or the other. Fortunately, in part because he is a member of the senior group advising the Foundation on such matters, Dr. Crawford is in a good position to do something about his suggestions, so I am not going to spend very much time on this except to say that with respect to his last suggestion on the business of individuals doing some teaching while on fellowship tenure, I think he will agree that this is a question which has been given a great deal of thought and concern. There are not really any easy answers as to how exactly one should go about this, for the simple fact is that what holds for geology and oceanography does not hold for mathematics; what holds for chemistry does not hold for psychology, and what holds at institution X may or may not hold at Y, but it surely does not hold at Z.

In the national programs that we must concern ourselves with, you have to write rules, regulations, general guidelines that are nationally applicable. This is where one really runs across some very difficult questions when it comes to anything that is mandatory, and I think Dr. Crawford was quite wise in saying that this thing should not or could not be mandatory. So much for that one point.

In connection with the general question and the one that you led off with, Mr. Chairman, concerning the statistical picture in the United States on manpower in these areas, I personally have been wearing a hair shirt on this particular problem for a number of years. Here the question has been, and remains, why doesn't NSF do this? Why doesn't it do that? We occasionally encounter—as for example among the group assembled here this morning—some people who really know the situation who will say NSF has been doing a lot, and that what it has done is justifiable.

The question that really is at issue here has been put before you by both Dr. Wolfle and Dr. Brooks earlier, and that is this: there is an absolutely insatiable desire on the part of those who are interested in information. No matter how much you get, there is always a great deal more that is wanted. This is not to say, and I want to emphasize this strongly, that we feel we have done all we should have done, or all that we perhaps could have done in terms of the resources available to us. But in connection with one of the colloquies here earlier, a question was raised as to the attitude toward the appropriations that the Foundation has had in this general area, and I quote to you a sentence or two from an appropriations report for several years back.

> The budget estimate includes $800,000 for making national science policy studies. The committee reduced the item by $50,000, which is indeed a very small amount, and it will expect the agency to greatly reduce this item next year. Many of these studies are of doubtful value and should be curtailed.

This is not a unique statement, and it is the kind of thing that we have to work with and around and try to sell our product better as time goes on.

I personally feel we at NSF have done a relatively poor job of selling the need for this kind of information, despite the fact that we know it, and the fact that many people who want this kind of information come beating on our doors day by day. But it isn't

necessarily the same thing to know that something should be done and to have the resources to do it.

Mr. DADDARIO. Dr. Dees, I would like to make a comment in that regard. I think the importance of the discussion we are having in hearings relate themselves to bringing to the attention of the other committees of the Congress the facts surrounding the needs on such a subject. We would hope that when these hearings are finished that we can come to some determination as to the importance of having the kind of information which you are talking about, which has received that negative kind of assistance in the past. Dr. Killian has referred to this in his remarks as being so important that it should be under a single agency, and with the National Science Foundation having an important partnership role, if not being the only agency involved. I think the important thing is not to say that the National Science Foundation has not done what it should have done, but recognizing that it does have a limited appropriation, to find out the reasons why it has not and to see what can be done to increase support where necessary.

Dr. DEES. Please don't misunderstand me, Mr. Chairman. I am perfectly, at least I hope I am, aware of the general attitude in this room on these matters. My point was simply to make the point for the record that in the past it is true that we have known what should have been done, we have wanted to do it. We have not always been able to get the resources to move ahead on these things as fast as we felt we should. This is highly correlated with a number of the points that have been made by those who have been discussing this particular issue this morning.

Mr. Douglass, as he points out, was present before the entire committee of this same name some years ago in connection with these matters. He made a number of points, all of which I think we would have wanted to agree with or disagree with in detail, but in terms of the general thrust there was certainly no quarrel, but the fact of the matter is, as Dr. Trytten has pointed out, there are certain things that you must do in order to have a basic background of information. By the time we have done that amount, plus the kinds of things that have to be done in responding to special requests from groups such as the President's Science Advisory Committee, and so forth, it is frequently so that our overtime bill has already run up to a point where we simply cannot work people any more, and the problem, therefore, is a very acute one.

Now, I wanted to make a few, and I hope somewhat more substantive, comments with respect to several of the points that have been made. We are doing a great many things, even despite this rather dismal story I have just been telling, which are at least relevant to the basic issues that have been put before you this morning. Let us take, for example, the one that was raised concerning the percentage of all degrees—the percentage of engineering degrees as a percent of all degrees. I am still not saying this right.

At any rate, the fact is we do know something about this, and we have been funding a group within the engineering fraternity made up largely of operations research specialists to try to get to the root of these problems. We also for years in fact have been supporting,

as much as we could, work on the general question of motivation, the identification of creative scientific talent, and so forth.

I could have brought, and you see with me a 2-inch stack, something of the order of a 2-foot stack of reports that have resulted either from our own direct work in such areas, or the work that has been carried out under the auspices of the Foundation by grantees or by contractors.

I think I would only wind up, Mr. Chairman, by making one point straight for the record in connection with a point that Dr. Terman made. The expenditures by the Foundation in the general area of what we call supplementary training for teachers are about the same this year as those which we will make for support of graduate students. In 1967 we will be spending even more on the direct support of graduate students in this area. If one takes into account the support of graduate students through research grants also, I think it is probably so that we have been in the same ball park in these two areas for a long time.

On the other hand, I think, with Dr. Killian, that it is necessary to look at the timespan that one is talking about in trying to assess the appropriate distribution of funds as contrasted with the long-range future when one is trying to do something about upgrading quality over a long period, and the business of getting more out of a given crop of college graduates into graduate school where we all know, without any debate, that if you go too far you will have to dip too far down into the barrel in terms of quality. So the question that we have always faced in this connection has been this very difficult subjective judgment as to what makes sense over time, not what makes sense this year or next year, but what should we do in order to make sure that 20 years from now the United States is as well off as it possibly can be, given the kinds of resources now available in these areas.

Thank you, Mr. Chairman.

Dr. KILLIAN. Mr. Chairman, may I say I think this long-term problem is probably the most acute problem that we are addressing ourselves to today. The fact that we didn't 10 or 15 years ago get started in creating additional centers of strength in this country is going to be a real handicap down the road. If we don't now do something to continue this process of strengthening fundamental education we are going to suffer from it 10, 15, or 20 years from now.

Mr. DADDARIO. Dr. Killian, you touched on the point of creating more centers of excellence. This is really not a question of geographical distribution. I wonder if you would expand on that.

Dr. KILLIAN. I would simply elaborate on that that I think it takes such a long time and so much effort to create these kinds of centers that we have got to find those that have the greatest potential right now and move ahead and give them support wherever they may be if we are going to increase our capacity in the shortest possible time.

I fully agree in the long run it is terribly important that we get a fuller geographical distribution of the centers than we now have, because we need to have more centers of strength accessible to other parts of the country where they are not accessible now.

Mr. MOSHER. Is it easy to measure the potential? Is there a generally understood criterion to determine this potential?

Dr. KILLIAN. This is a very difficult and in many ways a kind of subjective process. But I would say every agency, every agency granting funds, whether to industry or Government or a private foundation, has to make this judgment as to what is good, what is promising, what has the greatest potential. I don't think we should back away from it, and I think it can be done with reasonable action.

Mr. MOSHER. The motivation, the climate of desire?

Dr. KILLIAN. Yes, sir.

Dr. CRAWFORD. It is at least as easy to do as to identify the promising graduate students from those who will not turn out so well in graduate work. It does involve subjective judgments, as Dr. Killian has said, but it is the sort of judgment that can be done. It is tricky, but it can be done, yes.

Mr. DADDARIO. Dr. Terman.

Dr. TERMAN. This matter of centers of excellence is really important, because if you just look at the flow of people coming through our colleges, beginning now, and those who will be getting on to graduate schools, there isn't the capacity in the existing strong graduate schools to take care of the needs, and no reasonable expansion of those will do the job. So you have to have more centers of excellence and, of course, this is going to react back down through the undergraduate program as well.

The Seaborg Committee issued a report on November 15, 1960, nearly 5 years ago which says "Additional centers of excellence are needed." Again the Gilliland Panel report in 1962 says the same thing. As time passes the urgency becomes greater because the emergence of new centers hasn't kept up with the growth of the college population in recent years.

Someone asked the question about geographical distribution, how do you identify it, and so on. Well, I have been involved with a new center of excellence for though it may be hard for people to believe it now, Stanford was an underprivileged institution as of 1945. This is the place where I have lived most of my life, and I have seen it emerge. These are things that you don't do overnight. You don't create a great center in 1 or 2 or 3 years. You build and you strengthen and you build some more on the last successes, and gradually you emerge. It takes a lot of effort, exerted over a long period of time, and it takes leadership. The quality of an educational program is only—this is perhaps an oversimplification—is only loosely connected with the dollars that you pour into it beyond a certain minimum of dollars. An awful lot is determined by how much you get for the dollars you are putting in, whether you get a lot or a minimum amount. This is a very important factor.

I think also the geographical distribution will almost automatically take care of itself if we get more of these centers. If we have 30 really top centers in engineering and science, as against 15, or if we get 50 instead of 25, the additional ones are going to be inevitably spread. You are not going to start another one in Boston or on the San Francisco peninsula or in Pasadena. They are going to be in different locations obviously. So you almost get an automatic dispersal.

Mr. DADDARIO. I do not recall exactly how you phrased it, but you said something about the fact that student support is somewhat equally

attractive as the quality of education they might get at one place or another. How do you fit that into this whole process of growth?

Dr. TERMAN. Well, you cannot get first-class students to go to a place if there isn't the means for them to live after they come there as students. I am talking about the graduate level. At the undergraduate level the tradition is for the families one way or the other make major sacrifices to support the youngsters.

Dr. KILLIAN. This varies by fields.

Dr. TERMAN. Yes. I am talking about the science and engineering areas. In law there is a theory that if the youngster gets into law, he might make money, and the family will try hard to provide support. The same is true in the graduate schools of business and medicine, but to a less extent now than at an earlier generation.

You can have a fine faculty, and so on, but if you don't organize the finances to support the students, then you find it isn't practical for them to go to your school for their advanced training in science and engineering, and they go elsewhere where the support is available.

We see this in our university. The departments that organize their financial aid program will get the students, and the departments that are equally good as far as the stature of its faculty, and so on, and don't do a good job in providing financial support don't get them. Students apply and then don't come because they have financial problems that aren't being solved.

Mr. DADDARIO. Mr. Roush.

Mr. ROUSH. Mr. Chairman, it seems to me that the potential for these centers of excellence already has a pretty fair geographical distribution with the possible exception of certain areas of the South where I think some work has to be done. It seems to me also that in developing these potential centers of excellence we are going to do more than just develop that particular institution. It will tend to upgrade other institutions in the area which themselves may become potential centers of excellence. I know in my own State, Indiana, that the excitement which comes from the activities on the campus of Purdue has an effect on the programs of Indiana University and Notre Dame University, and vice versa. It seems to me that this will be one of the things which will come from this attempt to develop these centers of excellence. I would hope that the program could be accelerated in order that we might have this geographical spread of activity throughout the country.

Thank you, Mr. Chairman.

Mr. DOUGLASS. Mr. Chairman, this is a heavyweight panel, and I am painfully conscious as we are introduced that I am the only person who isn't a Ph. D.

Mr. DADDARIO. You have plenty of company.

Mr. DOUGLASS. At this point I just would like to say something that I think is terribly important, and we might forget it in all this talk of fellowships. There is a disastrous fact of life that even people who go to 4-year colleges perhaps should have left after a couple of years. There is a fad which brings lots of mail to my office—parents who are disappointed that their son dropped out of college. I don't think that they realize, many of them, that the colleges count on the dropouts. They wouldn't have room if everybody stayed.

Dr. KILLIAN. But they don't count on them.

Mr. DOUGLASS. It is a statistical fact of life that people do drop out, and it is an added fact of life that people should not be second-class citizens if they have a 2-year college education. There should be some concentration of pride at each of these levels. You need the excellence in the 2-year man. As a matter of fact, the excellent 2-year man can make the excellent 6-year man look better if there is a good working arrangement between the 2-year man and the Ph. D.

Dr. CRAWFORD. I just want to bring out, Mr. Chairman, in your inquiry about the attraction of fellowship support for students, a note I would like to underscore, if I heard it correctly, a note of concern for the student. It is true, I think, that you can run into a danger in this center of excellence buildup if you desire to establish and upgrade existing institutions; you can run into a danger by providing an institution with fellowships before it has a really adequate graduate program to offer the student. This can be a very real thing. There is a process in building up a graduate program which involves money and time—quite a lot of time, quite a lot of money, for that matter—and it involves a concern and an integrity and a leadership on the part of the institutions' administration. That process involves first recruiting some good faculty members so there is a program of at least the minimum integrity, minimum quality. There is help available for institutions that want it. The Council of Graduate Schools has a much-used consultation service for institutions who are seeking to improve their graduate program. They get very hard-hitting and informed advice and counsel, from this independent group, the Council of Graduate Schools. At some point in the build-up you have an institution where, although you cannot offer the graduate student quite the education that he would receive at Stanford, he can receive a graduate education that would be beneficial to him. At that point the institution really needs fellowship support so it can begin to attract graduate students, because once you begin to attract graduate students this aids in building up the faculty. You have kind of a circle, if you will, that has to be broken into at some point and then rolled around to build up into a center of excellence.

Mr. DADDARIO. I have a question which I would like to direct to Dr. Killian, but it does not necessarily exclude anyone else. It goes back to this question of information.

In regard to the study made by the Committee on Manpower Utilization, you talked about the need for having a single agency with the authority to coordinate manpower information. I am not necessarily suggesting that NSF do this, but I thought it would be helpful if you could develop that line of thought further.

Dr. KILLIAN. May I refer to the specific recommendation that was made by the National Academy Committee on Manpower Utilization, of which I was Chairman, on this point. Its recommendation was that:

Responsibility should be assigned to a unit within the Executive Office of the President for (*a*) stimulating and coordinating planning by Federal departments and agencies with respect to scientific and engineering manpower, (*b*) promoting research both inside and outside Government that is likely to facilitate such planning, and (*c*) taking the lead in developing an integrated program for the continuing collection and analysis of information relative to operating and policy persons on scientific management and manpower. While the com-

mittee does not recommend a specific location for this unit in the Executive Office, it notes the feasibility of placing it in the Office of Science and Technology.

That was a carefully considered recommendation of this committee at that time, but I would emphasize the fact that it did not want to designate a specific location beyond suggesting this as a possibility. It would seem that if this coordination and collection and evaluation feeds into the planning process, it must be so located that it can be related to places where decisions are made.

Is this responsive to your question?

Mr. DADDARIO. Yes, it is. I am just thinking about how it relates to accomplishing these other objectives. What are the levels of technical competence of which we are capable, and how do we achieve the goals that Dr. Lecht has referred to for the years ahead. How important is it that we accomplish this, and accomplish it quickly so that these projections can be more meaningful than they now are.

Dr. KILLIAN. My response to that was if we had available a group, even an individual, but a group particularly which was concerned with this problem, which could be instigators and stimulator of the kinds of things that need to be done, both in the private sector and particularly in Government, that this would help us make headway.

I don't see that we have that single place at the present time, to initiate and instigate and to stir up. This is not a criticism of the National Science Foundation. I agree that it has done a superb job, but the problem is much broader than the NSF area of activity.

Dr. DEES. Mr. Chairman, may I make a comment on this, because it is I think important that we at least not fail to say what exists at present.

Several months before Dr. Killian's group published what is now known as the Killian report, a recommendation was presented to the Director of NSF that there be established in the National Science Foundation, correlative with the office which is responsible for the mass data collection of information of the sort that we have here, a group that would concern itself primarily with science resources in the country generally, including but not limiting itself to the area of manpower.

This group has now been established. It has been in being for just over a year. We are beginning to make some progress with respect to the kinds of things that were recommended in the Killian report.

We are not claiming that this is the answer to the various questions that were put there and the problems that were brought out there. We do feel that many of the kinds of difficulties that existed before when we had no explicit staff arm working on this kind of problem can now be at least ameliorated. The group is a small group. It will this year have only about a half million dollars for outside grants and contracts. But this in itself does represent a major step so far as NSF is concerned in the direction of trying to make sure that depth analysis that will penetrate more deeply than we can do in the objective factfinding studies will in fact become possible.

Dr. KILLIAN. May I make one further comment, that the Executive order establishing the President's Committee on Manpower—it is a Cabinet committee—clearly had among the responsibilities of that Cabinet committee this general domain, and I would judge that the

Cabinet committee is considering ways and means of setting up this more centralized evaluation.

Mr. DADDARIO. Are there any other comments?

Mr. Vivian.

Mr. VIVIAN. I have a series of questions, Mr. Chairman.

First of all I would like to endorse the remarks made earlier by Dr. Terman, that it is virtually impossible to have a graduate program in the sciences unless there is additional support for students to live. With the age where people marry into the less-than-28 bracket, this will become a continuing problem.

I remember my days at MIT well enough to know that most of my compatriots at graduate school were supported by the mission agencies. Without that support, I think the graduate school would have been half its size. I think the same is true of Stanford. I believe the NSF has played a totally insignificant role.

Dr. TERMAN. Until recently.

Dr. KILLIAN. It has set a standard that is enormously important to every other agency in the Government.

Dr. CRAWFORD. I think it is relevant to say that the NSF fellowship program and the program for support of graduate students has been the best administered and has been the model.

Dr. KILLIAN. That is what the dean of our graduate school said.

Mr. VIVIAN. All the major centers of scientific excellence have been heavily supported by the mission-oriented agencies, especially DOD. Irrespective of whether this is good or bad, I think it is largely true. NSF is playing a larger role today, which I am glad to see. I am in favor of that. However, my remembrance of NSF's fellowships is that by the time my family had one or two children, which is not the exception but the rule, I could no longer live on an NSF fellowship. I would have had to subsidize my income by other methods. As a consequence it was easier for me in many cases to work part time or full time as a practicing engineer or researcher, and to continue my education on a part-time basis.

Therefore, I have some doubt as to whether the NSF fellowships satisfy the needs. On a competitive basis I think it can be pointed out that many people do not take them, not because they would not be accepted, but simply because they could not live on them.

Dr. TERMAN. There was a revision of the stipends upward about 2 years ago that has made a major difference. It used to be a quality program that was underfinanced. This has not been completely cured but it has been enormously improved.

Mr. VIVIAN. I am glad to hear that, and I apologize for being out of date.

Dr. KILLIAN. Plus availability of sufficient loan funds.

Dr. TRYTTEN. Plus the availability of a remunerative employment for the wives of graduate students.

Dr. KILLIAN. We try to provide employment for as many of the wives as we can that want it.

Mr. VIVIAN. That is an interesting step since I was there. My wife went to Boston University. I have covered that subject sufficiently. I am glad that it has improved.

I would like to go on to the subject of the $39 billion 4 percent figures that were quoted awhile back. I have used these figures in

a speech and therefore I hope they are right. However, I have a suspicion that they were based on a projection which all of us would find difficult to substantiate if one with a sharp ax were to go after it. I am sure that is a situation you can do nothing about. It is impossible to give an accurate prediction. I have been fascinated to find a gross absence of what we call adequate mathematical models of the economy sufficient to support my own actions in Congress. Therefore, I ask what you use as a model for predictions over the years. The amount of money which would be spent by NSF should be based to the extent possible on a competent econometric model. Do you feel you have an excellent model to predict the $39 billion and 4 percent?

Dr. LECHT. The National Planning Association over the years has developed a consistent detailed model of the economy, including all the major components, and we use this model for projecting purposes. It takes into account recent trends in imports and exports and productivity changes by industry, labor force participation rates, and changes in the location of industry. The projections of the trillion dollar GNP are based partially on this model, partially on tendencies in the years before making this study in the early sixties. They are also based on the fact that, according to President Kennedy at about this time, an annual growth rate of about 4 percent was a feasible target.

This, according to the President and the Council of Economic Advisers, was what the country could be reasonably expected to achieve.

Mr. VIVIAN. Let me shift to NSF. What models do you use when you depict the need for scientists and engineers?

Dr. DEES. Basically the Bureau of Labor Statistics, which has done the major studies that we have funded in this connection, have used trend lines but based on the disaggregation from all scientists down to and including the kinds of things that one can dig out of the available statistics on trends by industry, trends within Government, trends within the universities and colleges, et cetera. We are at the present time trying to develop growth models in two general areas, one at the university level, being done at Michigan State University, and one, which we still are frankly searching for some people to work on, which will have to do with the general area of the interaction between, let us say, investment in the centers of excellence programs and what will happen 5 years from now in terms of needs for more project grant money, what will happen when we and others put *x* millions of dollars this year into new graduate laboratories in terms of the needs for graduate student support 5 years from now, et cetera.

Mr. VIVIAN. I personally think there is much more work left to be done. There were remarks made earlier as to the number of graduates dropping from 10 to 7½ percent, the question is, is this significant?

In other words, how do you measure the significance of this set of numbers against the models you have? To what extent do you feel the models are adequate?

Dr. DEES. My own judgment with respect to this, Mr. Vivian, at this point in time is that we don't have enough experience with anything that is or could be called a sophisticated model to have any real judgment to make on that particular question.

We feel that it is clearly desirable to get some experience with this sort of thing, and then by retrospective looks after we have made some

judgments and some statements that planning can be based on, one can begin to make some further decisions on whether these are useful.

But I think that one of the things that needs to be remembered in connection with most of these projections is that by their very nature they tend to be self-defeating. If one comes up with a projection that there will be an oversupply 10 years from now of *x*, this in itself will see to it very nearly that there will be a shortage 10 years from now or conversely.

Mr. VIVIAN. One of the studies indicated that the requirements for industry would greatly exceed the needs for Government. It is hard to prove that today, because I believe something like three-quarters of all the R. & D. funds are Government funds.

Dr. LECHT. We were talking about the source of employment, irrespective of who financed the research.

Mr. DADDARIO. I think Dr. Trytten has a comment to make.

Dr. TRYTTEN. The only point I wanted to make is with regard to what Dr. Dees has said. I think there is a great deal of lag here between the kind of information he suggested and the effect on whether people do or do not decide to go into a field of study. The decision is based on a great many other things than their projection of what the job market is going to be at any particular time. It depends on what kind of home influences they will have, what their personal interest is, and a good many things. Wouldn't you agree?

Dr. KILLIAN. And what the impacts of their teachers are.

Dr. CRAWFORD. That is an awfully complex bunch of factors that influence this vocational choice or educational choice.

Dr. TRYTTEN. Over the period of time these transient balances of supply and demand are less and less sufficient.

Dr. CRAWFORD. You can gather statistics, and this is very, very fine, but first you have to make sure that the statistics mean something, that they weren't just filled in by the village postmaster, as the old saw goes, writing down what he pleased—you have to go back and ask whether a sensible question was asked. Does it make sense to ask a graduate dean how many students *will* get their Ph. D. *during the coming year?* We get this every year.

Having the statistics, then you have to do the interpretation. This takes a lot of time. It does take support. We mentioned the Graduate Record Examination as a useful tool. Everyone knows it should be improved. The Council of Graduate Schools would like to improve it. It costs money.

Mr. VIVIAN. I happen to agree that the graduate records examination is very important.

Mr. DOUGLASS. Here is one of the things that you must concentrate on in this whole series of statistics, I don't know that any industry depends for its planning on 2- or 3-year-old information. In the construction industry, F. W. Dodge gives daily reports throughout the country. In this manpower business, any prediction that is made today can be changed by the events of tomorrow.

Dr. LECHT. Mr. Vivian raised the question of the decline in engineering degrees as a percentage of bachelor's degrees. This is historical data published by the National Science Foundation in one of their very new and excellent sources, *Scientific and Technical Manpower Resources.*

Mr. VIVIAN. I am concerned with your predictions for the future and how significant they are in terms of how much money we put into it. My feeling is that the models we are using to predict what is going to happen 5 or 10 years from now are exceedingly inaccurate.

Dr. LECHT. I think there may be another problem, and that is the problem of what these numbers are. I personally much prefer the term "projections" to "predictions." Our ability to predict the future 10 years from now in these areas is poor indeed. I should add that "prediction is not the purpose of the estimates.

Mr. VIVIAN. Could you predict within plus or minus 3 or 4 percent in these areas?

Dr. LECHT. These numbers indicate possible alternatives for policy and the expected consequences of pursuing them.

Mr. VIVIAN. The budgets of the mission-oriented agencies, such as DOD and NASA, have pretty well leveled off, yet the image of the age is that we are going to be a science-dominated nation over the next 10 or 15 years.

Now if we take both curves—the funding of these major agencies and the prediction of the Nation's economy—somewhere in between there is an enormous gap, and it isn't just 1 or 2 percent.

Dr. LECHT. In that particular area, I suspect one of the areas of gap in that $39 billion is the role of R. & D. financed by industry out of its own funds.

Mr. VIVIAN. This is estimated as being $4 or $5 billion, and that has flattened out more than the other two. I am going by NSF statistics. I hope they are right.

Mr. DADDARIO. I think Dr. Lecht indicated an increase in research in many areas where very little is being done now.

I imagine your projection shows that these will be important national goals. Certainly there are indications at the moment that we will become more involved with problems of pollution and transportation. These programs will be very large.

Dr. LECHT. Yes. And there again this is not a prediction. I don't think anyone in the world knows how much we will be spending on R. & D. in 1975. What we have attempted to do is take the current programs which are under discussion as areas of need, and as far as we were able, either through Government studies, or studies of the National Academy, or private experts, we have attempted to estimate their cost now and 10 years from now. Summing up all of these areas including the R. & D. for defense and space, we come out with this figure of $39 billion for R. & D. expenditures in 1975.

Now whether we will achieve these needs is a question which would be difficult to answer until we are much closer to 1975.

Mr. DADDARIO. Dr. Dees, I thought you had an area of disagreement with Mr. Vivian. If you do, I would like to hear you.

Dr. DEES. I wasn't sure what he was speaking of when he spoke of this 3 or 4 percent. Maybe you were speaking of the 3 or 4 percent of the GNP.

Mr. DADDARIO. He was referring to the 3 to 4 percent that Dr. Lecht mentioned.

Dr. DEES. I misunderstood perhaps what you were speaking of, but I thought you were saying that we would be unable in any one of these

areas, let's say in the production of Ph. D.'s, to predict within 3 or 4 percent.

I would say that we are probably in no position to predict—predict as contrasted with project—closer than to 25 to 50 percent. What will happen and what we will say will happen the day after tomorrow or sometime soon is likely to be off by far more than 3 or 4 percent.

Mr. DADDARIO. Mr. Vivian, I believe Mr. Douglass has some comments on your last remarks.

Mr. DOUGLASS. I think the Congressman on the subject of models has been beating a bit of a dead horse. I think the panels have been open in admitting that the models aren't that great. It is much easier to predict soap sales because you look at the population, you know they are going to be born and they are going to need soap. But when it comes to the manpower subject, no one who publishes a study is particularly happy about it.

Dr. Killian was in the process of writing a report in 1963 when the whole demand changed completely. All the models were thrown out. No one had seen the possibility of what happened then. So the need for a new model, I think, is obvious, and the cost of it, as Dr. Dees says, is going to be great if it is going to be done. It is going to be great because it is a very complicated business.

On the other hand, I think it is worth looking into because there is also a tremendous amount of money spent (a great deal more than it would cost to find out about this market), based on assumption, opinion, and lack of adequate information, so I hope it will be looked into.

Dr. DEES. May I add to one point that Dr. Lecht made, the fact his own organization—I realize he is speaking as Lecht rather than the National Planning Association this morning—has just published a rather interesting report on the feasibility of projecting national budgets, Federal budgets——

Dr. KILLIAN. National goals.

Dr. DEES. This was, I think, a little different, Dr. Killian.

Dr. KILLIAN. I am corrected.

Dr. DEES. It actually has to do with whether it is possible to make some kind of stab at guessing what the President will ask for in the future. This is highly relevant to the question that was raised a few moments ago by Congressman Vivian, because until one is able to make some kind of guess on that point, it becomes extremely difficult to make any kind of guesses on the subsidiary matters which obviously depend tightly and couple very, very closely to this number.

Dr. TRYTTEN. If you find out how to do that, the President is going to find out about it and adjust his tactics.

Dr. CRAWFORD. I think it is probably relevant to say that I, like most graduate deans, have significant interaction with the NSF, calling on them for statistics and help in making my own projections, and it certainly is true, I believe, that in Dr. Dees' group they not only collect statistics and try to fit models to them, but that they are constantly seeking to improve these models.

It isn't a matter of getting the right model; it is a matter of hopefully improving your approximation with increasing experience. But there is a long way to go before that model is as accurate, say, as the models that we can use in the physical sciences or even the biological sciences.

Dr. LECHT. In this connection, Dr. Terman and several other people have pointed out a very important problem for research; that is, the relationship of R. & D. and economic growth. We have subjective judgments and qualitative studies which indicate that economic growth is substantially influenced by R. & D. But so far we have little quantitative evidence of what the implications are of increasing R. & D. expenditures. Some of the CED economists made estimates of this influence a few years ago, and one or two others have been working in this area.

What we could do in terms of projecting either R. & D., or economic growth, or manpower demands, would be significantly improved if we knew more about how R. & D. affected the processes of economic growth, either on a nationwide basis or regionally.

Dr. KILLIAN. Is this not also true of the effect of education on economic growth, which is an area that is just beginning to be explored?

And may I make one comment here, that I would make a projection that the enormous impact of what is happening in the field of education today through the Elementary and Secondary School Act and the other things that Congress is doing or considering may profoundly affect this whole manpower picture, particularly the demand for teachers.

Dr. CRAWFORD. We hope it will.

Mr. DADDARIO. Mr. Brown, did you have a comment?

Mr. BROWN. I will try to be brief.

Throughout our discussion here this morning, we have been talking about scientific and engineering manpower, and in previous sessions of this hearing I have been concerned about just what the experts mean when they say scientific and engineering manpower, the theme being I think that in practically all cases we are talking about the physical scientists and engineers.

I would like to raise this question and ask for an indication. Do any of you gentlemen in any of your remarks here intend any other significance or meaning than physical scientists and engineers in what you have said? In other words, is this not what we are talking about? If any of you differ from that, I would like to know about it.

Dr. KILLIAN. Mathematicians and teachers.

Dr. TRYTTEN. And the biological sciences.

Dr. CRAWFORD. I would like to include even some of the harder social sciences although I think that Dr. Terman was right when he pointed out that the greatest shortages are in the physical sciences, mathematics, physics, engineering, and so forth.

I think the biological sciences are probably the most exciting area of intellectual activity at the present time, and I think as we want to exploit the tremendous discoveries that are being made in biology, we are going to want to do something about basic biological sciences.

We were speaking about the need for sophisticated models in econometrics and sociometrics and converting guesses into predictions. Certainly this is an area that is important. I would say that the sharpest need is in the area of the physical sciences, but I would not myself by any means want to rule out the other sciences.

Dr. KILLIAN. But you include the biological sciences in the physical sciences?

Dr. CRAWFORD. No, I was making a separation.

Dr. KILLIAN. The need of the same sort exists in the life sciences.

Dr. DEES. I just want to say with respect to the statistical base which we have had threading through all this discussion it is true as of this instant that some of our studies have not included the social sciences partly because it is so very difficult to get a definition that makes sense. Here I refer in particular to the question of social scientists employed by industry, where the distinction between an economist and a market analyst or a person who is concerned with advertising techniques is extremely difficult to draw. We have thus far found that the industrial groups that we consult with have said they simply cannot give us these data.

However, other than that, all of the data that we secure on scientific and technical manpower resources include conceptually the social sciences, and we are trying to move to a point where this will be included uniformly across the board.

Dr. CRAWFORD. I would like to just include one mention also. You were speaking about going out from the physical sciences through some of the social sciences. While I don't believe there is anything like the shortage or the great demand in the fields of the humanities, yet when Dr. Killian speaks of the need for good teaching of science, this is very, very true: you cannot educate a good scientist by teaching him only science. We shall also need teachers and good teachers in such fields as history, English, the classics, and the humanities in general.

Dr. TERMAN. I would like to come back to the biological sciences and life sciences. We have to a certain extent skirted those because this area is in pretty good shape relatively speaking.

The National Institutes of Health at the time of the Gilliland committee 3 years ago was putting in something like $120 million a year into training new research people for that field. I suppose today it is $150 million. This field is so much better financed in terms of developing the manpower that is needed in the field as compared with the engineering, mathematical and physical sciences or the social sciences that manpower for the health field is not the burning problem that these other areas are.

This is important. After all, health is very important, and this is an area also where enormous advances have been made in recent years and will continue to be made. But there is a better organized manpower program there, better keyed in with the total needs, and better financed in relationship to those needs than in other areas.

Dr. CRAWFORD. I differ with you a little bit. I guess it is better financed, but I don't think it is better organized. I would make some criticisms of the way in which some of those fellowships, traineeships, research support programs, and professional programs are organized.

Dr. TERMAN. Perhaps, but I think part of the criticism is they have been pretty wealthy and have not had to operate on a shoestring.

Mr. BROWN. How does this apply to the supply of personnel in the practice of medicine and in the related health professions? I understand they are in very short supply.

Dr. TERMAN. I am speaking of the scientific activity in the biological and life sciences. These are the people who are generating new

knowledge. Of the money that I am speaking of—none is available legally to go to training medical practitioners, and there is certainly a real shortage of practicing doctors at all levels.

Mr. BROWN. I think this problem needs to be analyzed. Why do we have a surplus of funds for the training of researchers and a shortage of practitioners in the field?

Dr. TERMAN. It is partly the way the funds have been appropriated and partly the enormous expense of developing new medical schools and expanding the present ones to handle more students. It comes to a matter of dollars. Dollars have been available for one purpose and they haven't been for another.

Dr. DEES. May I just add one point here, which I think is highly relevant.

At NSF we are extremely conscious of the fact that ours is a relatively minor role in the area of the life sciences, but I do want to emphasize one thing that I think ought not to be forgotten in this general connection—namely, that NIH, by virtue of its specialized mission, cannot have as much interest in, let us say, systematic biology, the classification of plants and animals, and so on, as they must have in some of the areas which are at the cutting edge of research that has to do directly with improving the health of the Nation.

As a result, I think that the comments that Dr. Terman has made, though basically correct, nonetheless do not speak to the question of the life sciences in general. They are primarily concerned with the life sciences as they are reflected through the eyes of a very competent administration that is concerned primarily with how to make sure that the human beings in this country, particularly, have longer and better lives.

Dr. CRAWFORD. I think, though, from where I sit in my university it is certainly true that both the medical and the basic biological areas are more nearly adequately supported, let me say, than the physical sciences and the engineering sciences.

Dr. KILLIAN. But there are still aspects of biology that are not touched by that program.

Dr. CRAWFORD. Oh, yes. And this, in turn, is more easily supported or easier to advance in than the social sciences or the humanities.

Mr. BROWN. I am interested in your criterion of adequacy, because this requires that we stipulate as to some preconceived level of what is adequate in these fields. Right now our criterion is based on the demand for scientific and engineering personnel in three or four major governmental programs such as the defense program, the atomic energy program, and the space program. Is that not true? Are these, as I think Mr. Vivian pointed out, essentially artificial criteria in view of the changing levels which could throw our projections out substantially insofar as future needs are concerned?

Dr. KILLIAN. Mr. Brown, we also must base our estimates on industrial needs that are not related to defense or space or other Government programs.

Mr. BROWN. It seems to me we must give increasing emphasis to our industrial needs because of the fact that perhaps this area has been shorted. The competition from these other areas has drawn scarce manpower away from these fields. However, I do not know how

we can be precise as to what the trend line will be in the private industry sector.

I am also deeply concerned about the emphasis which has run through all of your remarks that we are in a scientific and technological society today. As I think Dr. Terman pointed out, the quality of our civilization is determined or affected by this supply. However, if we are talking about just the physical sciences and neglecting the social sciences—the anthropologists and the economists—I would tend to differ with that. I think science is not just the physical sciences, it is much more than that. The quality of our society today is affected by excellence not only in the physical sciences, the hard sciences, but in all of the sciences that have to do with the study of man.

Does the Panel differ with that?

Dr. KILLIAN. Certainly not this member of the Panel. I agree with you completely and heartily. I am in favor, incidentally, of a National Humanities Foundation.

Mr. BROWN. I am not even talking about humanities. Humanities and sciences have traditionally been differentiated. Science has a broader connotation than mathematics, physics, and biology.

Mr. DADDARIO. Do you have a comment, Dr. Trytten?

Dr. TRYTTEN. I was going to say one of the striking things about undergraduate students is the degree to which they leave some of the hard sciences, as you are putting it, and move into some of these areas, and these are not necessarily the students of failing caliber, they are very good students, but somehow have the feeling that the problems of today lie in the area that you are talking about. There is a substantial amount of that kind of migration.

It is evident, for example, in a report put out by the National Opinion Research Center, I believe financed by the National Science Foundation, on the graduates of 1961. You can find some very interesting information in there about how students move around in the undergraduate years, shifted from one field to another, and some of these that you speak of as the hard sciences tend to lose out.

Mr. BROWN. We need to understand the motivation that causes this moving around. We may be pumping dollars into the hard sciences and competing with the motivation which more and more undergraduates have to move into a field which they feel is more relevant to the problems of society today.

Dr. KILLIAN. There is no doubt that this influence is taking place.

Mr. BROWN. I would like to know what the record indicates in terms of the increase or decrease in the percentage of graduates in the physical sciences during the last 10 years, as compared to the previous 10 or 20 years? Has there been a substantial increase?

Dr. DEES. The percentage has slightly fallen at the baccalaureate level in the physical sciences and risen in the social sciences.

Mr. BROWN. Does this not indicate what I am saying?

Dr. DEES. Yes, I think it does.

Dr. LECHT. Again, speaking in terms of the social sciences and needs, mention has been made of the need for better economic models and data, and I certainly agree. As a nation we are embarking on many new programs which presuppose a great deal of social science knowledge, in economics, in sociology, in psychology, in social psy-

chology. The war on poverty presupposes a great deal of knowledge as to motivations of people in attending schools, or getting a job, or maybe keeping out of jail, or getting rehabilitated. Our regional redevelopment programs presupposes a great deal of understanding of why people want to stay in an area or can move out, or how you get them to move out if you are thinking in terms of broader regions and promoting regional growth.

Similarly, our anticrime programs presuppose that we know how to treat criminals and why they are criminals. Obviously we have some of this knowledge, but we don't have nearly enough. We draw broad distinctions between hard and soft sciences, and I am sure those distinctions are there, but to a considerable extent the criterion must be the criterion of needs. In terms of needs, many, many things we are doing right now make it important that we improve our scientific knowledge in both the physical and the social sciences.

Mr. Brown. I would pose the possibility that one of the reasons we have such emphasis on the physical sciences is because of the relative ease of defining goals. We want to buy $5 billion of atomic energy science, $20 billion of space science, or something like that—the goals are fairly simple to define. They are not that simple to define in the areas which you are talking about. This is another reason why I am talking about the effect on national goals.

Dr. Killian. May I make a footnote on this.

In my own institution our experience has been in the last 10 years that the increase in election by students in various fields shows that management, economics, and, broadly, the field of the social sciences have gained more than any other field. A larger percentage of our students are going into these fields at the present time.

Mr. Brown. I wish we could learn to carry over some of the structure that we have in the physical sciences and engineering and feel that the social sciences are really sciences, and that public administration is really the engineering of political science and business administration is the engineering of economics as a science, and that social welfare and criminology and that sort of thing is the engineering of sociology and psychology.

Dr. Crawford. I think this is sort of a historical sequence. Certainly 50 years ago—I spoke of Maxwell's equations versus network theory—50 years ago, a little more than that, Maxwell's equations were a fine thing for basic physics, but their contact with reality was always with the fudge factor put in. You might design on the basis of science, but then you put in a factor of two. I think you call it a safety factor in engineering circles.

Physical science has grown, it has matured to the point where it does make contact with reality, and you can design a circuit, you can design a polymer in the chemical world, and predict in advance within let's say 5 percent what properties that unsynthesized compound will have. So it is not just a matter of being able to define the problem. I think it is simply the fact that physical sciences are perhaps 50 years ahead of the biological sciences, which are in turn perhaps 30 years ahead of the social sciences, and my 50 years and 30 years are—what was the term?—projections.

Mr. Brown. I think both of them are probably about 100 years or 200 years behind philosophy and the development of social goals that we should have.

Dr. KILLIAN. I think there has been a steady gain in qualitative aspects of the social sciences, and the quantitative which is very important. But there is still a long way to go to receive the effectiveness that they need.

Mr. DADDARIO. Mr. Vivian, we will be finishing in a few minutes, do you have any other comments?

Mr. VIVIAN. Yes. I think Dr. Terman made reference to the fact that international competition on the sale and distribution of products is increasing very rapidly, and we were going to have to pay a great deal more attention to the economic aspects of the subject of marketing. I think we are training far more people who are able to orbit space satellites than we are people who are able to continue to sell products overseas. I think this could be a disaster of no minor consequence.

I know, for example, there is the Sloan fellowship arrangement at MIT, and many people have their own programs. I am concerned with that partly because I have recently tried to sell products overseas. I noticed enormous differences in price which did not favor us. I think we might ask ourselves if we are doing enough in the colleges in terms of education for an international market. Are we, for example, training our engineers in the nature of the national markets and the price factor as influenced by different distributions of manpower and automation? Are we really training engineers these days or are we training people who have no contact with the commercial side of the enterprise?

I received an education in the engineering-economic relationship in 1945 in a school which at that time was teaching by the routine of the 1930's and they still had economics in the curriculum. Later, however, at MIT and Michigan I received almost no training on this subject because I was becoming an expert in Maxwell's equations.

Perhaps curriculum studies run by NSF might include engineering not as engineering per se, but rather engineering as a career and a predecessor to commercial enterprise. I think about 50 percent of all corporate managers are engineers by background.

Dr. KILLIAN. That is correct.

Mr. DOUGLAS. I think NSF has its hands full making for technical excellence. If you gave a man everything that he needs in life, you would give him Harvard Business School for a couple of years, you would give him the Foreign Study School out in Arizona for a couple of years; he would be in school for half his life. It is really too much to turn out every person this well rounded. Even the effort to give them the humanities, such as Dr. Killian has mentioned—I think the National Humanities Foundation—I don't know where I've been; I think it sounds like a wonderful idea—this could be a concern of another area. I don't think the NSF people should concern themselves with——

Mr. VIVIAN. Let me make one last point. If we are to guide our behavior today by the criteria of the 1930's, none of the major programs that are now in existence would ever have gotten off the ground. I think this evolution of rising expectations which prevails throughout the world shows itself in America through the total change in economic patterns, and I say, shall we go on with it?

Dr. DEES. In a different part of our shop from the one which deals with the course content improvement sort of thing, we have for a number of years been helping groups to look at the patterns of education. With respect to this very question that Mr. Vivian has raised. there is going forward at the moment, under the dean of engineering at Stanford (for the graduate component) and under Dean Hawkins at Purdue (at the undergraduate level) a set of studies designed primarily to look at exactly this broad question, not as it relates explicitly to international problems but as it relates to the question: "How should engineers be trained 5 years from now?" It is clear to those of us who have sat through discussions of this kind in detail on a number of occasions in the last few years that the so-called Grinter report that came out about 12 or 15 years ago, now, and which had a great deal to do with setting the patterns for instruction in the engineering sciences in institutions throughout the country, is viewed already as out of date. The pendulum swung probably a little too far in the direction of science as the main thing in engineering, with too little emphasis on the question of design and the question of economics, and all these other things that are imbedded in this very large complex which you have spoken of. These two studies are looked to by the engineering fraternity as possible ways not of determining what institutions will do in detail, but ways, rather, of helping the institutions to determine desirable trends over the next few years. The problem of imbedding, as Mr. Douglass has pointed out, into a 4-year engineering degree all these things is becoming an increasingly difficult problem. It may be, as Dr. Terman has pointed out, completely impossible, but it is certainly still true that a great many institutions are going to continue to turn out 4-year engineers, and they ought to be turned out in that period well adjusted to the times, and, as the dean of engineering at MIT has said several times, with a currency that will be valid for at least 10 years. So one can hope, therefore, that this kind of study will, in fact, by bringing together large numbers of people who have thought through these problems in considerable detail, have some impact on this problem.

Dr. KILLIAN. I think there is a correction factor working here to get back into the engineering motivation and interest, perhaps formally in the curriculum, a greater concern with cost and economic factors.

Mr. DADDARIO. In a sense, what Mr. Vivian is talking about is that which you have all touched upon on occasion—quality.

Mr. DOUGLASS. Just a very brief comment. I didn't mean to sound unkind on this subject. It is just a question of "something has got to give" as you get more in here, because really from the employer viewpoint a lot of employers want just good working engineers. They don't really want him to be a manager. They want him to be interested in his profession. We may get too involved in making him into all sorts of things that maybe he doesn't even want to be. This, I said earlier, should be up to the individual. There is obviously identification of excellence in people. If we can give a person that which he needs, this is fine.

Dr. KILLIAN. One of the conclusions reached in this study is that the most acute shortage was of those men who had a deep insight into technology but in addition the management skills that would put the team together to really make it work.

Mr. DADDARIO. I would have liked to have discussed NSF's science development programs, and whether or not you support this program. I think it might be a step toward the accomplishment of these centers of excellence that you have mentioned. However, we do not have time to go into it now.

I want to apologize to all of you for keeping you so long. We have gone considerably beyond 12 o'clock. There is now a rollcall in the House for which we must qualify, so we will stop at this point.

I want to thank all of you for what has been an exhilarating discussion, and one which has been very helpful to the committee.

This committee will adjourn until tomorrow morning at 10 o'clock in the same place.

(Whereupon, at 1 p.m., the subcommittee adjourned until Thursday, August 5, 1965, at 10 a.m.)

NATIONAL SCIENCE FOUNDATION

Seminar on Science in Small Colleges

THURSDAY, AUGUST 5, 1965

House of Representatives,
Committee on Science and Astronautics,
Subcommittee on Science, Research, and Development,
Washington, D.C.

The subcommittee met at 10 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. Daddario. This meeting will come to order.

This is our next to last day of hearings on the National Science Foundation. Dr. Haworth will appear as our final witness on August 19.

I am pleased to welcome today Dr. Sanford Atwood, president of Emory University, Dr. James P. Dixon, president of Antioch College, Dr. Katharine McBride, president of Bryn Mawr College, Dr. John E. Sawyer, president of Williams College, and Dr. Richard H. Sullivan, president of Reed College.

It is our intention in this seminar this morning to look into the relationship of the small colleges to science and research, and their relationship to the National Science Foundation. This committee is concerned with the place the small colleges have in this Nation's scientific research programs, and the role it will play in the future.

We had an opportunity yesterday to discuss the question of scientific, engineering and technical manpower with a panel which added a great deal to the hearings of this committee. I would like to use the same format with you distinguished participants this morning.

Would you care to start, Dr. Atwood?

STATEMENT OF DR. SANFORD ATWOOD, PRESIDENT, EMORY UNIVERSITY

Dr. Atwood. Thank you, Mr. Chairman, ladies and gentlemen.

The theme that all of us on the panel are emphasizing today highlights the college—the small college of liberal arts and sciences. We are proclaiming its vital role in the best possible preparation of the Nation's sorely needed scientific brainpower. In effect, we are saying that Government funds in support of science training are just as important for the good colleges as they are for the good universities. If the Government neglects this valuable collegiate resource by funneling

disproportionate aid-to-science funds to the already oversized and strongly research-oriented universities, it will be cutting off Uncle Sam's scientific nose to spite his new space face.

Although we're joining in a chorus, each of the panelists properly should stress his or her particular verse. The situation at Emory College within Emory University is a significant deviant from that of the other colleges represented among today's seminar participants. The pattern from Emory is that of the small liberal arts college, which like the others is very select in its admissions and very high in its standards, but which at the same time is nurtured in the congenial atmosphere of a medium-sized university where there are unusual opportunities through intimacy for interdisciplinary research and teaching.

Emory is a university that includes not only the traditional master's and Ph. D. programs but also a full array of graduate and professional offerings such as medicine, law, and business. We are granting more graduate and professional degrees than baccalaureate degrees, and approximately two-thirds of the former are at the doctoral level.

Last year we renamed the undergraduate college. It used to be called the College of Arts and Sciences, but now it is called Emory College. This was done purposely to accent the original and crucial role of the undergraduate college, now making its way in a university environment. Emory began as a college in 1836 in Oxford, Ga., and it didn't aspire to be a university until 1915, when it was granted a second charter and the campus was moved to Atlanta.

In recent years, the college has rapidly increased its selectivity, so that the incoming freshmen have been chosen with essentially the same standards as those of the best schools in the country. If this year's graduating seniors were to apply again as freshmen, over one-third would be below the cutoff point for admission. Even so, more than 80 percent of this year's B.A. and B.S. male graduates are planning to engage in graduate and professional study.

My point is that this kind of high-level undergraduate training—for science and all other fields—can and must be duplicated in every region in the Nation. Only in this way will we foster the best opportunities for discovering and developing the full mental resources of this country, which we know are not distributed with any geographical priorities or with any allegiance to race, creed, or color. And lest you're worried about the kind of teaching at Emory or other such colleges, let me assert that the faculty resources necessary for top-level education of such outstanding students have been and are being attracted to this kind of college within a university.

Perhaps I can illustrate with a few case studies about students and their professors. First, the story of Jim Bolen. Jim was reared in a small town in southeastern Georgia. The youngest of four children, he was supported through school by his mother, who works as a secretary. He had an excellent high school record—3.8 average on a 4-point system—and he engaged in a wide variety of extracurricular activities. His SAT scores were in the 600's but there was no basis for predicting his spectacular college record. Every grade that he received during his entire college career was A, except for four B's, and he was graduated last June with a major in chemistry and No. 1 in his class. Throughout his 4 years he was involved in many activi-

ties outside of the classroom, including several roles in student government and the presidency of his fraternity. He received all top honors, such as Phi Beta Kappa.

Jim and Emory first came together in the summer of 1960 when he attended the NSF High School Institute. When he entered as a freshman in the fall of 1961, he was placed in an honors section of general chemistry, and he was consistently top man in his section. At the end of his freshman year, he entered the NSF undergraduate research participation program, an opportunity that is usually reserved for upperclassmen. Jim elected to work with Dr. J. H. Goldstein in the area of nuclear magnetic resonance. His work was so outstanding that Dr. Goldstein hired him as a research assistant during the 1962–63 academic year. He has continued his research as an NSF participant in the summers of 1963, 1964, and 1965, and during his senior year he took a year's course in quantum mechanics that usually is limited to second- and third-year graduate students.

His research has centered about structural studies of molecules of biological significance such as cytosine, pyridine, and the pyrimidines. He has given oral papers for the past 2 years at meetings of the Georgia Academy of Science. The general caliber of his research performance has been that of a Ph. D. candidate. This fall he probably will enter the Johns Hopkins Medical School, although he is trying to work out a plan for a combined M.D. at Hopkins and a Ph. D. at Emory.

There is no doubt about the NSF program being instrumental in focusing his attention on research and giving him the opportunity as an undergraduate to work with a distinguished professor in a very close personal manner. Without the assistance he received from NSF, Jim Bolen could not have utilized his abilities to the fullest extent.

Another case demonstrating the value of summer NSF programs is that of Bob Harrison. He was a participant in the geology section of the NSF-sponsored summer science institute for high school students at Emory in 1963. At that time he had completed the 11th grade at Venice High School in Florida. Because of the NSF experience, he returned to Emory in the fall of 1964 as a freshman intending to major in geology. Last spring he was awarded the honor of being the freshman with the highest academic average. It is significant that he first came in contact with geology through an NSF program and was attracted to Emory to major in this subject.

Likewise in physics, the undergraduate NSF research program is reaching into the freshman class. During this past year, Robert Warnock, a freshman from Alabama, devoted a sufficient portion of his time in the Solid State Laboratories to prepare and present a research paper in the area of thermoluminescence before the senior section of the Georgia Academy of Science.

More exciting, however, is the case of a senior, Wallace Mathews, who last year conducted a series of experiments on room-temperature optical bleaching of KCl during gamma irradiation. It's of interest to note that he used the hospital's teletherapy unit for his irradiations on weekends and during evenings when there was a light patient load.

Wallace is a native of south Georgia, where his father is engineer for the Thomasville Waterworks. As a career scholar with Pro-

fessor Mallard, Wallace studied the mechanisms of color center bleaching induced by relatively low radiation dose levels in alkali halides. At the same time, the Solid State group at Oak Ridge and the Hazards Control Department at the Lawrence Radiation Laboratory, studied the same behavior at very high radiation doses. Wallace's data matched beautifully the Oak Ridge data in the region where the experiments purposely overlapped. Strikingly unexpected results of his unique experiment in the low-dose region substantiated a mechanism for vacancy-interstitial pair production of F-Centers and weakened the case for two other competing models. Wallace presented his results before the American Physical Society at the Washington meeting this spring, and they will appear in the Physical Review in a report on the Emory-Oak Ridge experiments.

This summer Wallace is assisting with the NSF undergraduate research participation program, and in September he will begin graduate work at Boston University.

Similarly our mathematics department has conducted NSF institutes for high school students every summer since 1960. One student, Wayland Brown, who was in the first institute, has just graduated from Emory with high honors. He has been awarded an NSF fellowship and a Woodrow Wilson fellowship and is entering the University of Washington to work toward a Ph. D.

Another former undergraduate math major, Russell McMillan, was awarded an NSF fellowship at the University of Wisconsin. Currently, he is an associate professor at the University of Virginia and a Sloan fellow and is regarded as one of the best young topologists in the country.

The mathematics department also has conducted in-service institutes and summer institutes for high school teachers with NSF support since 1957. Because of this NSF support, a new degree program, master of arts in teaching of mathematics, was organized, and presently is in a very flourishing state. Approximately 28 teachers have graduated with this degree, and this summer there will be 12 more. This program has significantly influenced the quality of mathematics teaching in Georgia high schools, as demonstrated recently in the Mathematical Association of America national examination, when the three top schools and top students in the State had teachers trained in this program.

From the examples cited, and many more like them, it is obvious that Emory and other small colleges are serving well as grassroots centers for the selection and training of scientifically superior students. The small colleges, geographically distributed as they are, can reach into areas and tap pools of potential scientists that would not be reached by the few large university centers of excellence. While such large university centers are being developed, the National Science Foundation might well support, as an equally important investment, those small colleges that themselves are geographically well distributed centers of excellence. Only in this way will we provide adequate opportunities for finding and developing the best scientific brains everywhere.

Mr. DADDARIO. Dr. Atwood, you touched on these case histories. How would you relate that to further progress? Do you have any idea how these case histories can be improved, and how we can attract

not just those of such high rating, but others who can still be competitive?

Dr. ATWOOD. To do the job, we need large numbers of such institutions, and we need them well distributed geographically. The best opportunities will come in those schools that are select in their admissions and provide this stimulating atmosphere which steers the students toward graduate work.

Some of our colleges are preparing a disproportionate number of boys for graduate and professional work, which, after all, is where the scientist is trained. Such colleges need help from the National Science Foundation, whether it is undergraduate research participation, whether it is grants for faculty research, whether it is equipment funds, whatever will attract the good professors and thereby attract the good students.

Mr. DADDARIO. You like, then, what has been done, but you feel there is room for improvement?

Dr. ATWOOD. I like very much what has been done. I would like more of it.

Mr. DADDARIO. Dr. Dixon.

STATEMENT OF DR. JAMES P. DIXON, PRESIDENT, ANTIOCH COLLEGE

Dr. DIXON. I shall add only a brief chorus, if I may, to Dr. Atwood's testimony about the effectiveness of the relationships which we at Antioch College have had with the National Science Foundation. The thrust of my remarks will not be so much to explore the question of regional centers of excellence as to explore the possibilities that the small liberal arts colleges may indeed be a primary source of scientists for many years to come, and my remarks are an effort to examine the possibilities of additional support by the National Science Foundation of undergraduate education as a primary source of scientists.

Historically the small liberal arts colleges have been highly productive of scholars in the physical and social sciences, and despite the rising enrollment in the large, publicly supported university, the burden that will be placed on small colleges will be consequential in the decades ahead. The master plan for higher education in Ohio, for instance, calls for doubling the enrollments in the private colleges in the next decade. The small liberal arts college will continue to be an important source for recruitment and pretraining in the disciplines of physical and social sciences. It will no doubt continue to do this in an environment that is heavily weighted with the concern for the liberal arts, which is to say that such a college will be oriented to treating all of life as if it were vocational, not merely teaching the student in the discipline in which he chooses to specialize.

One senses, in examining the awards of the National Science Foundation fellowships, that very little emphasis is placed upon the necessity of making awards to graduates of liberal arts colleges. This suggests that the National Science Foundation puts a very heavy emphasis at the undergraduate level on preprofessional training, and that it may be missing the opportunity to support explicitly the primary function of the liberal arts college, which is to educate the whole man. In missing this possibility, it may be failing to uncover creative

scientists who will not, at that point, present the most elegant preprofessional training credentials because they will have chosen to use their undergraduate opportunity to extend their learning beyond their major fields of interest. The National Science Foundation may also be failing to support the education of citizen leaders who are equipped to manage humane science policy.

In recent years, there has been a modest growth in the superiority of research in the small liberal arts colleges by the National Science Foundation, in another dimension these colleges have been very successful in assisting the National Science Foundation in the admission of the improvement of the teaching sciences in the secondary schools. But the small liberal arts college has special problems. Feeling the responsibility to introduce students to the widest possible horizons of knowledge, it lacks the high degree of specializations in its faculty that characterize the large university.

Indeed, in the physical and social sciences, it may be safely said that faculty members in the liberal arts colleges are regarded by their university colleagues in the disciplines as second class. The college teachers cannot compete with their university colleagues for the political roles in their fields that make them effective in negotiating national policy at the Federal level.

Few small liberal arts colleges have thought that they could afford many faculty members whose principal occupation was research, and the effort to fit scholars into a combination of teaching, counseling, scholarly and research roles often results in the fragmentation of their time in such ways as to make it unreasonable to expect them to carry on extended research activities.

Furthermore, the small colleges lack the resources to invest in physical facilities and libraries on a scale which can compete with universities. The small liberal arts college, then, has special administrative problems in managing the time of its faculty in order to accommodate the research and investigation. It must be said failure to do this has often made it difficult for such colleges to recruit a faculty that by its own standards would be adequate.

Some of these problems of scale might be overcome if it were possible for the National Science Foundation to develop a program of institutional grants, and here I don't mean the present program of institutional grants, not a program which is based upon a percentage activity of what is already underway, but a novel program of institutional grants that would permit the small colleges to rearrange teaching time and emphasis to the best advantages of the undergraduate students and the development of the faculty. Such grants, too, would simplify the problems of small colleges in dealing with the Federal Establishment. Universities can have on their staffs persons who specialize in such relationships, but the small college either must depend on the ingenuity of its faculty members to find support for their own projects, or must wait to be sought out by the Federal agencies.

The relationship between the National Science Foundation and the small liberal arts college deserving to be greatly strengthened is that for the preparation of teachers for college teaching. So-called teaching interns can be added to the programs of the small college rather readily, and the environment of the liberal arts college, at least in the eyes of the college, is particularly suited to such internships, for as

yet scant attention is paid in graduate schools to the preparation of graduate students as prospective professors.

Finally, much more could be done in developing relationships with groups of colleges for all small colleges will be plagued with unevenness of quality in their faculties and need the opportunity to draw on each other's strengths. Such a consortium is the Great Lakes College Association, made up of colleges in Ohio, Michigan, and Indiana, which is in the midst of a very successful internship program in chemistry and biology financed by a private foundation. But it wishes to go beyond that to find ways to improve the quality of all undergraduate teaching. Such consortia should be stimulated to specialize and learn how to use each other's resources, particularly at the advanced undergraduate years.

The relationships between small colleges and the National Science Foundation deserve to be more intimate and effective than they are at the present. Not only should it be possible to extend present relationships in support of faculty and undergraduate research, and the improvement of the preparation of teachers at all levels, but because of the problems of scale the possibilities of making institutional grants designed to draw from each college its greatest productivity should be fully explored. Such institutional grants, it should be noted, should not be made just to colleges that have achieved excellence, but to any institution that can demonstrate a plausible program for improvement.

Thank you, very much.

Mr. Daddario. When Dr. Wiesner testified here a few days ago, he threw out the suggestion that to help in this faculty arrangement that perhaps a science teaching corps might be established to fill these needs. Do you have any thoughts on that?

Dr. Dixon. I haven't thought about it. I suppose one's first response is a little defensive. One observes the high mobility of faculty members, and if such a corps were to increase the mobility of one's faculty members, one might have some reservations about it.

I take it that he had in mind a program in which the preparation for membership in this corps would be supported in some way by public funds?

Mr. Daddario. Yes, I think so. We did not go into it in any depth, but you have put forth some suggestions here in this regard. I just thought that perhaps we should add Dr. Wiesner's suggestion as another avenue to look into.

Dr. Dixon. We tend, I think, in our liberal arts colleges, to sometimes disguise the inadequacies of the level of quality which we have in the physical and social sciences. For most liberal arts colleges it is extremely difficult—even for colleges of excellence—extremely difficult to get and hold a faculty that is adequate to do the preprofessional training that the universities will regard as appropriate for the admission of graduate students. We have trouble saying this publicly because it is with a sense of concern that we have had to admit this weakness.

The places where we have real peril in quality of faculty is in the physical sciences and more recently in the social sciences. I think this is why it is in our own self-interest to be concerned about the teaching of teachers and in our own self-interest to get behind any national program that would help do so.

Mr. DADDARIO. Our next participant is Dr. Katharine McBride. She not only is president of Bryn Mawr College, but also a member of the National Science Board, and therefore has had a very close relationship to the development of the activities within the National Science Foundation.

Dr. McBride.

STATEMENT OF DR. KATHARINE McBRIDE, PRESIDENT, BRYN MAWR COLLEGE

Dr. McBRIDE. Mr. Chairman, I appreciate the opportunity to meet with my colleagues on the Panel and with the members of the Committee on Science Research and Development, under your chairmanship. I thought that I might present to you a case study which would show the variety of NSF programs in one college, and that is what I have chosen to do.

First, I should perhaps say briefly that Bryn Mawr is a small institution, with about 1,100 students, about 115 members on the faculty. Among the students, 750 are undergraduates, all women, and 350 are graduates, both men and women. So, like Emory, we are talking about a small institution. Ours happens to be called a college, but it is a combination of undergraduate college and a graduate school. About 15 percent of the undergraduates take their degrees in the natural sciences and mathematics, about 25 percent in the social sciences. Among the graduate students, the percentages are just about reversed. About 26 percent take their degrees in natural sciences, and about 16 percent in the social sicences.

Members of the faculty at Bryn Mawr are interested in support for science and social science that will help us do more than we could otherwise do in basic research, in the support of graduate students, and in the development of better teaching.

Among the Federal agencies, we depend almost exclusively on the National Science Foundation, the Public Health Service, and in the field of social work, the Children's Bureau, also. We are not interested in contract research and almost never do any. In Federal grants of all kinds, we receive about $500,000 a year. That is about 10 percent or our total budget. The amount from the NSF in recent years ranges from $115,000 to $246,000. Those figures represent the range for the last 3 years.

We look to the NSF primarily for help in the support of basic research and in the support of graduate students. Members of the faculty have research grants in five different fields in science and social science. A research grant usually, as you know, provides funds for summer salaries for faculty members, part-time assistance for students and some equipment. We do not ask for winter salaries for faculty members. There is an occasional exception to this, and one that I should mention later.

The cooperative fellowship program and the new graduate traineeship program are helpful in the support of a few of our graduate students in the sciences. Other graduate students, a larger number, are supported through the part-time research assistantships which are part of the research grants to members of the faculty.

Grants under different programs of the NSF that are most useful to us for the undergraduate school are the undergraduate research participation program and the undergraduate instructional equipment program. In each of these we have grants in three different fields.

In the undergraduate research participation program, as has been noted, able undergraduates are chosen for an 8-week summer period of "independent study." Independent study is done in close collaboration with a professor and represents a kind of preview of the experience the student expects to get in graduate school, where concentration on a subject is possible and close collaboration with the professor is attained.

The students in this program, as has been mentioned for the students at Emory, are usually students who plan to go to graduate school, and this summer on the undergraduate research program confirms their choice.

The NSF institutional base grant has been mentioned. It is an unrestricted grant based on the total of all research grants made to the institution the year before. At Bryn Mawr it is expended on the recommendation of a faculty committee, chiefly for the following purposes: To purchase equipment that would not fit into any individual research proposal; to subscribe to additional scientific journals; to give partial support to younger faculty members or graduate students who are getting their research underway.

This, in our experience, is one of the most useful of all NSF programs. The amount is not large. In our case, for 1964, for example, it is $17,430. I looked at the grants to the other institutions here, and I find that Reed exceeds us all, so after the meeting I propose to ask my colleague Dick Sullivan how he manages this amount! But those unrestricted dollars are stretched by our faculty committee just as far as dollars can stretch.

We have had a few other grants for special purposes and I shall include them to show the range of NSF support. We have had one toward the cost of the research area in the building of the physical sciences which was completed in 1964. We have had two for in-service institutes for teachers of physics in secondary schools; we have had one for the development of a course in chemistry and physics which is still underway. That course involved the exception to our policy of not asking for NSF grants toward faculty salaries during the college term. To develop the course, two faculty members were released, half-time: that is, paid by the NSF grant. The grant will not be large enough to support them in the evaluation of the course, and its preparation for possible use by other institutions, and that we shall support from our own funds.

We have also had a grant jointly with Haverford College to develop a small computer center for the two institutions, which has now been in operation, I think, for 3 years.

It is, of course, hard to make an overall estimate of the effects of NSF support on a single college in the last 10 or 12 years. We have had at Bryn Mawr the same problems other institutions have, stepping up the work in science through grants increases college costs beyond any increase in the overhead. Stepping up the work in the sciences gives the faculty in the sciences some advantages over fac-

ulty in other fields, notably summer salaries. On the whole, however, the advances that can be made through the NSF programs greatly outweigh the problems involved.

Certainly we find that the faculty are more active in research than they were earlier, and that they are getting on faster, chiefly because they have more assistance and in general better equipment.

Certainly the NSF support with that of other agencies has substantially increased the number of graduate students.

Certainly also more people, both students and faculty, work a longer year than was true 12 years ago. Two weeks is the typical vacation now in the sciences and social sciences.

We also believe that the college that has not seen this kind of progress in the sciences would have the greater difficulty in making new appointments in these fields.

Thank you, Mr. Chairman.

Mr. DADDARIO. Thank you, Dr. McBride.

It is a little bit off today's subject, but we on occasion have referred to the relationship of the National Science Board to the Director. It would be helpful to us, I think, to get your view as to whether or not the National Science Board, as presently constituted, can on a part-time basis properly fulfill the role that was originally prescribed for it in the National Science Foundation Act of 1950.

Dr. MCBRIDE. May I answer that by going back a little bit to earlier years in the Foundation when I was, as Mr. Sullivan is now, a member of the Divisional Committee on Scientific Personnel and Education.

The Director met with that Committee usually and gave that one of the major committees of the Foundation a chance to discuss policy, program development, budget, and other aspects of the Foundation's program. I felt in sufficiently close touch with the work of the Board at that time to know that there is a great deal to be added to the report that was prepared for your committee as a preliminary to this review that you have undertaken.

For instance, I missed in that report the program development that the NSF staff and Board and committees work very hard on. The author of the report is likely to say that such a program appeared in such and such a year. I suggest that that program didn't appear without the most tremendous amount of preliminary work and exchange with the scientific community, and the tremendous involvement of the Board, its committees and the staff in the development of program I would like to emphasize.

More specifically in answer to your question in the present, I think you should note that we meet not only as a board but as a series of committees. I happen to be on the new Committee 1 of the Foundation, which is concerned with current program. We meet once a month in addition to the Board meetings, and we review major problems before the Foundation; for example, the situation in relation to the rapid development of the need for computers and the problem that we will face, not only the NSF but the Government agencies more generally, in the development of university computer centers.

I would say in general in answer to your question that we have a pretty extensive opportunity for discussion and exchange of opinion.

Mr. DADDARIO. The point has been raised that the chairman of the Board ought to be a full-time position, and that the Board have its own

full-time staff separate and apart from the staff help it now receives from the Foundation. What is your thinking on that?

Dr. McBride. I would question what the relationship of a full-time chairman and a board would be to a full-time director. It seems to me the agency should have one operating head and not two, and I would find it hard to see how a full-time chairman of the board would find himself in relation to the director.

Mr. Daddario. The suggestion that Dr. Walker made was that the director would be the operating head and that the chairman would perform the policy function somewhat in the nature of some corporations. The example of a school which used this management arrangement was MIT. It has a chairman and a president which apparently work harmoniously.

The other suggestion was that perhaps there should be a full-time staff, not a large staff, but a staff which might be available to the members of the board and the committees.

Dr. McBride. The staff in the contacts I have had with the Foundation is apparently able to find time to both meet with the board and prepare the materials requested by the board. We feel very close to the staff.

Now how we would use an additional staff I am not sure. As you talk about full-time and part-time appointments, I should perhaps say that some of us on the Board wonder whether maybe the part-time part of our work isn't our other job.

Mr. Daddario. I would think that you would find yourself in that position very often.

Thank you, Dr. McBride.

We will next hear from Dr. John E. Sawyer, who is president of Williams College.

I would just like to comment on the fact I have working in my office this summer a boy from my district who is a student at Williams College. I am happy to have him although some people feel me disloyal not to have a student from Wesleyan.

STATEMENT OF DR. JOHN E. SAWYER, PRESIDENT, WILLIAMS COLLEGE

Dr. Sawyer. Mr. Chairman, I am delighted he had that experience. He spoke to me before the meeting began and expressed his great interest in it.

To you and members of the committee I would like to echo my appreciation of the interest of this committee in the small liberal arts college. I think there is, as Dr. Dixon has very well said, serious danger that this important part of the structure of American higher education and of the supply stream of qualified scientists will be neglected in comparison with the highly visible capacities of the large research centers.

I think it would be a very great loss for America if science should wither at what has been a major source of young scientists and what is a very important part of our educational strength.

I would like to say that I think the NSF has done not only a helpful job but an outstanding job in strengthening science in America, and that American education is better for what it has done. I

would like to say that clearly because I am going to focus my remarks on ways in which I would like to see some diversion or increase of its effort in support of the liberal arts college.

Miss McBride has outlined very well the kinds of things that it is now doing. I think there is an acute need for it today more. I would like to speak of this under three main headings.

First, there is clear evidence that there is more capacity to give advanced training in science, Ph. D. training in this country, than there is supply of qualified candidates. I could quote from a report of the American Chemical Society a year ago:

> The numbers indicate that there are at present places available for graduate students, more places available than there are qualified applicants. In short, a rather desperate competition for students exist and probably will continue for some years.

And a statement from the American Physics Institute to the same effect:

> Physics is facing an increasing shortage of adequately trained baccalaureates, to meet the requirements that progress will place on the field.

That is, there is more training capacity for advanced work than the supply of well-trained undergraduate candidates, and it is right here that the group of colleges represented and those they are speaking for can make their contribution.

Second, I would urge the importance of sustaining first-class science at the strong liberal arts colleges and the value of having the Nation's future scientists come to science and come to either their professional or executive responsibilities with this background of education. It is important for scientists and nonscientists to have a broad liberal education and the high-quality independent colleges provide an instrument unique to this country, that has been built up and equipped to supply this.

Further, as Dr. Dixon indicated, a mainstream of future science teachers comes from the small liberal arts college. Students catch the spark, and Dr. Atwood referred to this, they catch the spark of a personal kind of teaching relationship that gives them an interest in this life commitment to go on into a career of teaching science to youngsters, giving a cumulative effect to this investment.

Third, I think it is extremely important to the future of this country that scientists not become educated in a world unto themselves, exclusively in a few large technical schools or universities, withdrawn from communication with other leadership groups and with the mainstreams of American life.

I think the liberal arts colleges are particularly suited to offering good science instruction on a broad liberal arts base and contact with men who are going into careers like yours and the many others that are necessary for a democratic society to cope with this modern world.

Mr. DADDARIO. Dr. Dixon referred to that, I think, as teaching the whole man.

Dr. SAWYER. That is right. And the kind of dedication, the number of science teachers that have come from small colleges are amply demonstrated. There is a study by Knapp and Goodrich a few years ago that shows the fertility of the small liberal arts colleges in producing scientists and the teachers of science.

The experience of providing good science education is a massive burden for the small colleges that take it seriously.

It is important, I think, to sustain a leadership group, and I am going to dissent I expect from people on both ends of this table in this respect. While geography should be respected, and any strong regional institution should be encouraged, I think the basis of support ought to be standards of excellence and potentials of excellence, the capacity to do the job; and because, for instance, in the Northeast there are more institutions with a strong past and strong potentials, I think it would be shortsighted to penalize them for this factor. Their capacity to feed students into this supply stream and to sustain this endeavor is the important thing. America needs the sum of these resources.

Now the expenses are real, and the ways in which NSF can be helpful Miss McBride has reviewed in a case study. I would like to quickly and briefly mention five kinds of things, all of which support what Dr. Dixon said: Increasing the capacity of the small college to retain and attract the able scientist who also wants to teach but in teaching does not want to cut himself off from research opportunities in his professional field.

I will briefly mention five here. First is clearly and importantly physical facilities. The costs of building new science buildings, new science centers, are pressing on all of us. We had a program which had very favorable staff response at NSF but which they were unable to fund when their own budget was cut in ways that precluded new programs, and among the new programs was one in support of undergraduate science institutions.

This hurt us directly and others in similar need of partial help in the financing of new science buildings. This was a particularly imaginative interdisciplinary science center that a group of our younger faculty had come up with, and it impressed me as an extremely fertile idea.

The second, related to this, are equipment and research assistance needs where NSF is helping on a limited scale now in both equipment and, as Miss McBride said, in participation in research in the summertime but where an expansion of this could be directly helpful.

Third is a balancing of teaching loads where the small college often has to ask of its faculty a much larger teaching burden than the large universities and the research centers. The availability of funds under the kind of new institutional program that Dr. Dixon suggested here would allow intelligent management of relief of teaching for a semester or a lightening of load when a young scientist has some particularly important work he wants to bring to fruition. These are opportunities that we could develop with the kind of institutional grant which he alluded to.

Fourth is contact with their professions, to help enable them to take time off and go to Brookhaven, or go to MIT for a semester or a summer or travel during the year or whatnot that will enable a man to keep abreast of his field. This is not only important for him, but critically important to transmitting the spark to the young people in college who are working with him in science and who are catching hold of the excitement there is in serious scientific research.

And fifth is summer compensation. There has grown up an arrangement under which people benefiting by Government contract, NSF and other grants, have a compensation during the summertime, typically two-ninths of their salary, which supports their summertime research.

As Dr. Dixon indicated, it is often less easy for even a good scientist at a small college to formulate the program, go through all the apparatus of getting a special grant. Here again an institutional grant could help in making this available, and I think you could with confidence feel that those small colleges—I think NSF knows well where centers of strength are—that are first class and are seriously concerned with sustaining first-class science would use these funds responsibly.

Hence, I would strongly urge not only the good record of NSF but the further support of activities that could strengthen science in the strong liberal arts colleges for the reasons I have briefly covered.

Thank you, very much.

Mr. DADDARIO. Thank you, Dr. Sawyer.

Do you have any comment, Dr. Dixon, on the question of geographical distribution and the helping of schools which have not as yet deserved the label of excellence, but which have the potential to develop excellence?

Dr. DIXON. I have thought a bit about this. I suppose it is not an either/or. To approach it sensibly one has to recognize that there are parts of the country that behave as regions, there are institutions that behave as regional institutions and tend to draw in concentric circles their students to them. There are, on the other hand, colleges—take ours as an example, if I may—which are in no sense regional. Located as it is in Ohio, not more than 5 percent of the student body comes from the State of Ohio. It is regional only in the sense of its potential cooperation with other institutions.

So you have the prospect of regionalization that is mentioned in the new Hampshire College, for example, that we have heard about in this last day or two.

I should think this is not either/or, that where regionalization can be demonstrated, it should be supported, and where potential excellence can be demonstrated, even though regionalization cannot be demonstrated—it, too, should be supported.

Mr. DADDARIO. Then there is not such a disagreement.

Dr. SAWYER. I would echo that idea. I would certainly say there is a strong case for supporting regional excellence where it exists. I would just not want to exclude other centers of strength, because there happens to be some concentration in given geographical areas.

Mr. DADDARIO. You were just being somewhat protective?

Dr. SAWYER. Yes.

Mr. DAVIS. I would like to point out that one witness heretofore has expressed it this way: It is unquestionably to the best interest of the country that we preserve the peaks that we have, and we should dedicate our efforts to filling in the valleys.

Dr. SAWYER. That is right.

Mr. CONABLE. The only problem with this is there is some limit to the resources available, and what we do at the peaks may have some impact on what we can do in the valleys.

I would like to ask Dr. Dixon if most of his students do not come from the Northeast, however.

Dr. DIXON. They come from the major metropolitan areas in the United States, except those metropolitan areas in the southeastern United States. They are rather evenly distributed.

On this question of regionalization, David Riesman has a theory about this. It is called "The more, the more," and his young——

Mr. CONABLE. Research begets research.

Dr. DIXON (continuing). And his young colleague, Christopher Jenks has a collateral theory, "The less, the less."

Mr. DADDARIO. In this regard, what comment do you have on the limitation which Congress has imposed upon NSF on the number of fellowships which can go to residents of any one State as it affects such areas as New York and California. Should there be a limitation?

Dr. SAWYER. If that is addressed to me, my own study of this problem and exposure to it has been more in terms of institutional needs. I have not studied that, and I do not know whether that is a limitation. I can see, perhaps, a need for a balancing of both here. It would certainly seem to be losing a source of talent, unless other forms of support are available, to cut off extremely able young men simply because they come from a given area.

Mr. DADDARIO. I would imagine all of you would agree with that proposition?

Dr. SULLIVAN. I might add this, Mr. Chairman, it seems to me, particularly at the graduate level, that limitations by particularly geographical subdivisions are especially unfortunate.

I think they are more unfortunate there, where we are producing a national resource that is highly mobile, where there is not necessarily much relationship at all between the geographic origin of the graduate student and where he will serve this country directly or indirectly. It is at this level that I think we should be particularly cautious about geographic divisions.

When you come back to the possibility that the Federal Government would be financing more undergraduate scholarships, then I think geographic considerations would be more relevant because by and large our students are attending high schools in the areas in which their families reside. This is less true once they are in college, even less true at the graduate level.

Mr. DADDARIO. I am glad you made that comment, Dr. Sullivan. I would appreciate it if you could just proceed with your prepared remarks.

STATEMENT OF DR. RICHARD H. SULLIVAN, PRESIDENT, REED COLLEGE

Dr. SULLIVAN. Mr. Chairman and members of the committee, I share the interest and pleasure of my colleagues here in being invited to speak to you today and feel like them that the committee is certainly to be commended for its interest in the effects of Federal science policy on the liberal arts colleges. I am sure your concern is recognized and appreciated well beyond just the members of this group who are here, today.

I think I would like to make it especially clear, like my colleagues, that while I am here by your invitation, I am here also as a friend of the National Science Foundation, which, in my judgment, like Dr. Sawyer's, has performed in an outstanding manner over the past 15 years. It seems to me that that performance by a higly competent professional staff has been achieved through generally a broad understanding of the needs that do exist today in our colleges and universities.

In part, that understanding has been aided in an important way by the use of and the employment of college and university personnel on leaves of absence from their home institutions and by the use of an extensive and thoughtful system of advisory committees. I might, in view of a few comments by my colleagues, mention one or two things about Reed College, simply as background for what I will try to say. Like Antioch and Williams, I believe more than like Emory and Bryn Mawr, Reed has been traditionally an undergraduate institution. We now have approximately 900 regular, full-time undergraduate students. Like those described from Antioch, they are drawn really from wide national spectrums, geographically.

I think Reed has had a somewhat unusual record in two respects: Traditionally it have been quite strong in science, and 40 to 50 percent of our graduates will, in a typical year, have majored in mathematics, physics, chemistry, or biology, which is an unusally high percentage for the independent liberal arts college.

Secondly, a very high proportion of our alumni have tended to go into teaching and research and to furnish the manpower for college and university faculties, a trend that one of my colleagues here has already alluded to.

One graduate program that I have been very happy to see develop very rapidly, has increased in terms of degrees granted by sevenfold in the last 6 years, which is quite a rapid rate of increase, even though the numbers are small, and this is the master of arts in teaching degree, which has been directed toward the better preparation and updating of groups of people who are particularly interested in secondary school teaching, and that degree program has paralleled the efforts of many of our faculty in the national curriculum development at the secondary school level and other programs of that sort.

We have had approximately the same variety of assistance and grants from the National Science Foundation that Miss McBride described for Bryn Mawr, so that our experience with the Foundation has been rather extensive.

It seems to me that the understanding and appreciation of Congress, sympathetic to the very large responsibilities of the Foundation, has also provided in that agency an administrative flexibility that is somewhat unusual in the Government. The Foundation has been allowed, with few specific restrictions, and most of those I think I would tend to oppose, to modify its programs when needed, expanding and contracting as experience and current necessities would suggest.

Over the years its program has been broadened to include institutional grants more than before, programs aimed primarily at the undergraduates more than in the past, and fields of knowledge other than the "hard sciences" where they started in the early fifties. The

specific expansions along with the principle of administrative flexibility to change and expand as our needs and opportunities change would certainly have my wholehearted endorsement.

I thought that it would be useful for me to call attention to two of the several Foundation programs which have the greatest positive impact on undergraduates and which are most helpful now to such administrators as we represent. I believe those have received some emphasis. I might give them a slightly changed one.

I refer first of all to those programs which are directed at the development of new strengths in faculty members, and I would like to make a special comment there. I think we are generally agreed in higher education that quite grave shortages of faculty members are in prospect in the next 10 or 15 years, even for the best of our undergraduate colleges with the highest prestige and for some of the graduate schools and universities. But in all types of institutions, however they are structured, that engage in undergraduate education, I think it is possible that the largest problem within this total problem may be in the numbers and quality of faculty available to teach lower division college courses. High school teachers or individuals with masters of arts in teaching degrees, rather than advanced degrees in subject matter may be called upon increasingly to essentially bear the burden of lower division college teaching, primarily junior colleges and community colleges, but also some 4-year institutions. The Foundation's programs for summer and academic year institutes are aimed at the secondary and college teachers. These efforts could help to meet this problem, particularly when supplemented by the Foundation's programs of curriculum improvement and development.

So I would suggest that consideration be given to even more support for colleges and the universities also, particularly in urban areas, to operate on a fairly sustained and continuing basis faculty programs and curriculum programs for teachers in the community colleges, which has been done in secondary schools. Such running seminars might contribute significantly to the faculty development, having in mind particularly the lower division teaching.

A second program that has been cited already this morning that directly affects our students is the undergraduate research participation program. Reed has had, since its inception, a requirement for all of the seniors of a special thesis based on engagement in research. That senior thesis has involved our students now for 50 years in a particular way of pursuing new knowledge, rather than keeping them primarily in the role of receiving and studying other research.

This same spirit now pervades the Foundation's undergraduate research participation program. We have had a good experience with it and others have already spoken of this this morninng.

I shall try to be specific in several suggestions which have occurred to me that I would like to present, not in a spirit of criticism of the Foundation's program to date, but simply in an attempt to identify some of the things that might be done in the future or with slightly different emphasis.

The first that I would like to suggest is that some of the colleges, as well as the universities, could be, I think, more involved in the task of information transfer from the scientific and academic to the industrial communities and to the general public. Most colleges recognize

a general responsibility to the communities in which they are located, and yet every college may hold a different view of the best manner in which to fulfill that responsibility. It would be possible, I think, for some of them to provide seminars on the latest scientific developments with the audience being the industrial scientists and engineers in this area, so that new knowledge may be more rapidly fused into the industrial sections of the economy. Perhaps these could be patterned after existing seminars for secondary and college teachers.

The Foundation has the responsibility for disseminating results of scientific research. To do so through the undergraduate faculties in this way as well as through the universities would speed the process while providing colleges with support for the very legitimate community service function that would be consistent with their educational role in our society.

Moreover, the liberal arts institutions recognize a future role to educate citizens. The Foundation could support the colleges in education of the general public so that the facts behind public issues involving science might be seen in somewhat better perspective.

Second, it is my understanding that the Foundation is moving toward meeting its share of the large responsibility of the establishment of an overall national science policy by cataloging science activity, particularly that supported by the Federal Government. It is possible at least that a "central bank" of data on Federal research grants and contracts will be developed to assist the rational allocation of scientific expenditures. With some additional effort such information may also be organized in an informative format which would assist college faculty and administration in locating sources of support for local activities, for basic project grants, for facilities, computers, nuclear reactors.

Especially the smaller colleges and perhaps those who have had a little less experience than the colleges represented here today, find it very difficult to have large staffs that are knowledgeable in these areas, and considerable time and effort might here be saved for them if an educator, for example, could come to a central reference catalog and advisory office, which would tell him where to seek support for the particular project that he or his faculty have in mind, what kind and level of support he might expect on the basis of precedents in different agencies, and what projects would be most appropriate for support. The Foundation could play in this way a very helpful role for small colleges by providing an orientation to all Federal science support, reducing frustrations and time spent in determining who deals with what programs in Washington.

Third, as will be the case in the next couple of years, the two present forms of Foundation support for graduate students include fellowships based on selection in national competition, and traineeships awarded by the graduate schools so to speak in internal university competition. It seems to me that it is possible that neither of these forms nor both taken together will fully take advantage of individual judgments by faculty members who work with the budding scientist when he is an undergraduate. Relatively small sums might be placed in the hands of the colleges themselves to be awarded to their graduates on the basis of their confidence in such students suc-

ceeding in graduate school, but whom the other two kinds of competition and support may have overlooked.

As the competition for admission to our best graduate schools inevitably is increasing, the impersonalized screening of applicants, based on grade point average and test scores will also be increasing. There is already some evidence of this. Some young people, and perhaps particularly in some of the sciences, who are quite promising in special fields, have not, during their college careers conformed to the grade-getting race, and can perhaps be identified and encouraged by the colleges who might otherwise be overlooked. I think this should not be a large program, but it might be a supplementary device.

Fourth, like my colleagues, I would hope that the Foundation may continue to expand its use of institutional grants to centers of excellence at the undergraduate level. There is perhaps an analogy to the umbrella grant system which the National Aeronautics and Space Administration has been using, but in this instance the institutional grant might be aimed at fundamental investigations in basic research, rather than mission-oriented research. Aside from the grants for a selected number of institutions which have been suggested as centers of excellence, a larger group doing some research might receive an institutional grant, broad anual support, for related research activities within a college and cutting across departmental lines. This would allow for flexible local determination of areas to be supported, it would help to raise in certain senses the level and style and quality of undergraduate education. It might help to keep more able faculty members in the colleges, rather than in the universities, and particularly might provide younger faculty members with encouragement and support for research at a time when they have not yet established records of publication which allow them to compete successfully for project grants.

One other observation might be in order. It is clear that a number of institutions are undergoing an important process of transition at the present time. The clearest examples may be those colleges, for the most part public, that until recently have been special-purpose teacher-training institutions, have now become 4-year State colleges with liberal arts programs, and in some instances, are moving on to a third stage as regional State institutions.

Another trend is perhaps not so widely known. Some private institutions, colleges of high prestige, are moving already toward adding more research centers and institutes to their programs, and adding gradual instructional programs in limited ways in fields of unusual faculty strength. It seems to me that such changes as this should be viewed with a great deal of encouragement, with flexible means of government support at early stages of these transitions, where that might be one of the better ways of increasing our total national resources of high quality in science research and education. There may be a little bit too much burden of proof on a showing by such colleges that they have already made such transitions before they are technically eligible for certain kinds of support. More and early willingness to encourage well-defined intentions to move in this way might be helpful.

I appreciate this chance to talk with you, Mr. Chairman.

Mr. DADDARIO. Thank you, very much, Dr. Sullivan.

Mr. Roush?

Mr. Roush. I wonder if each member of the panel could give us the basis for the support of your particular college? Is it an independent or a denominational school?

Dr. Atwood?

Dr. Atwood. Emory was started as a Methodist college in 1836. We would classify it today as a church-related university. The total church support is about 1 percent of our $35 million annual operating budget. We are in the same category as Duke and Northwestern and a number of other schools that were started by the Methodist Church, but have moved into this somewhat more remote relationship.

Dr. Dixon. Antioch is nonchurch related, nonuniversity related. It is what is called, I guess, a freestanding liberal arts college.

Dr. McBride. Bryn Mawr was founded by Friends, but not in relation to any meeting. It is an independent college.

Dr. Sawyer. Williams College is an independent college.

Dr. Sullivan. Reed has never had any church relationships. It is independent. Sometimes when I look at our financial problems, I think it might be described as a "free-falling" college, rather than free-standing.

Mr. Roush. Mr. Chairman, the reason I asked that question is I thought I might be a little critical at this point. I am a graduate of a small college, and I can appreciate its problems because for 16 years I have served on the board of trustees of a small college. My wife is a graduate of a small college, and we intend that our son be enrolled in a small college this coming fall. But it seemed to me that this panel, if I sense this correctly, is really not representative of all of the small colleges. There are hundreds, and I suppose thousands of small colleges, which may not have a very close church relationship, such as my own. I gather from what I have heard here this morning that the colleges represented all receive considerable support from the National Science Foundation, and maybe other governmental agencies. They not only receive this support gladly, but are perhaps dependent on it to a certain extent or at least they have a very liberal view toward accepting it.

I live in Indiana. We have, of course, fine universities there, but we also have small colleges, some of which are church related, which are very conservative in their view. Wabash and DePaul are good examples.

In my own district—and nothing could stimulate a Congressman's interest in a small college more than this—I have five small colleges, and they, too, tend to be very conservative in their view.

I wish, Mr. Chairman, that we had one of these colleges represented on this panel so that its president might address himself to the philosophical question involved in the acceptance of Federal aid and dependence on this type of grant.

Now, I don't say that this is my view. I spoke of sitting on the board of a small college; I am the liberal voice on that board. Each time my reelection rolls around, I wonder if they won't still that voice. It happens to be the only extra-curricular activity that I have maintained in the 7 years I have served in the Congress, and I would hope that they do not do that. But I do think if we are to get a well-rounded

view of the problem and the philosophy involved, that we should hear from some of these other people.

Then, too, there are colleges—and I had the president of one speak to me the other day—where the relationship between the National Science Foundation and the college left something to be desired. Probably it was just an administrative problem, yet it was something I feel that the committee should be aware of as it studies the functions of the National Science Foundation.

I might just throw this out in closing: Do members of the panel believe that the reluctance on the part of some of the colleges to participate, say, in the programs of the National Science Foundation is in any way deterring or holding back the progress which we might attain in the area of science?

Dr. Atwood. Mr. Chairman, I would like to call your attention, if you haven't seen it, to the study the Danforth Foundation has conducted recently. The preliminary report covers more than 800 church-related colleges in this country. It is the most extensive study of this kind that has been done. The staff work is still going on. They have had a series of regional seminars with all of the schools involved, at seven or eight locations around the country, and the full study, which will probably be issued during this year, is a book. But it does go into this question, along with lots of others, as to what should be the position of the small church-related college in relation to the acceptance of Federal support.

Coming, as I and Congressman Davis do, from the Bible Belt, I know the feeling that exists in certain of the institutions in our area. There are some of them that have no desire whatsoever to accept any kind of Federal money.

Mr. Roush. In not accepting this Federal money, are they really avoiding some of their responsibility?

Dr. Atwood. It is my personal view that they are.

Dr. Sawyer. Mr. Chairman, if I could comment on this, I would feel for most of the institutions, certainly one I am most familiar with, we are talking about something like 2 to 3 percent of the budget. The amounts are around a hundred thousand dollars from NSF in a college budget, and that is not a situation of dependence.

I believe, as Dr. McBride as indicated, an institution can consciously maintain policies such as paying its own faculty their regular salaries out of its own resources so as not to get into a situation of dependence or that might imperil its freedom of action.

I think some of the large universities, running into 20 to 30 percent of their income, and some of the technical schools have been much higher, have been concerned and have studied this problem.

I think for the small liberal arts college it is a means that does not distort their policies or purposes, but can enable them to do better the job that they are in business to do. I have not seen in any relation with the NSF anything that imperiled our freedom to direct policy and ways we feel are sound.

Mr. Roush. I gather, then, Dr. Sawyer, you are saying that within your experience there is no undue or inappropriate Federal influence on the part of the sponsoring agency?

Dr. Sawyer. To which we have been exposed at the levels at which we are recipients.

Mr. DADDARIO. Your level of participation with the National Science Foundation would probably be less than with some of the private foundations?

Dr. SAWYER. Right.

Mr. DADDARIO. You have that same flexibility I would expect?

Dr. SAWYER. That is right.

Mr. DADDARIO. Dr. Dixon.

Dr. DIXON. I am sensitive to the points which Mr. Roush raises. If a college holds as a matter of principle in its ideololgy a feeling about not dealing with the Federal Government, then there is no way probably to construct relationships which would be helpful there. But some of the concerns I think I have observed in the deeply religious colleges that surround us in Ohio have been the more general concerns of autonomy.

I would suggest that if one pushed a little more toward this institutional grant, which had in no sense coerciveness in it at all, but which says in effect you are a good institution, we accept the evidence that you are good, and we put no strings at all upon the ways in which you shall improve your quality in the sciences, that this would be helpful to some of the small undergraduate colleges that are struggling with this question of Federal relationships.

Mr. DADDARIO. Dr. McBride.

Dr. MCBRIDE. Mr. Chairman, I looked back to the report prepared for you and noted that in 1964 the number of institutions applying under the undergraduate instructional scientific equipment program was 780.

Now that, I should imagine, would be perhaps a third of the institutions that might be qualified to apply, but it is a pretty large number, it seems to me.

Mr. DADDARIO. Dr. Sullivan, doesn't one of your suggestions touch somewhat on this? If there were centers available through which all schools could better understand what was being done, and the degree of autonomy which they would have in the event they would participate, you might get more of them seeking this kind of support? They probably do not seek support because they are fearful of it without having real reason to be.

Dr. SULLIVAN. I think so. I might add this, I feel Mr. Roush's point that we are not directly representative of the generality of small colleges is well taken. On the other hand, I think each of us does have his own relationships in his own backyard with neighboring institutions that do permit us to make some representations.

For example, in Oregon we have the Oregon Colleges Foundation of which most of the private colleges, nearly all of them, are members and an independent college association, which does include all the accredited colleges, and most of those incidentally are denominational institutions unlike Reed.

I would say more than half of those dozen colleges are not in a position—have not had direct experience with grant seeking that has been really very helpful to them. Their staffs are very small, and they are somewhat bewildered in really how to go about the job, what kinds of support are available for them, and I don't sense in that group a hardened determination of any kind not to accept Federal funds under the proper conditions. I am sure there are many conditions under which

they would not and should not accept Federal funds. But we do not have a situation like the one that is quite well known that you have in Indiana. I think that is atypical, it is regarded as such. That may make it even more important.

Mr. DADDARIO. Mr. Mosher.

Mr. MOSHER. Mr. Chairman, in anticipation of these hearings, several weeks ago I wrote to the chairmen of the various science departments in my own college, Oberlin, and asked those chairmen to comment on their relationships with the National Science Foundation. I asked them also to invite some of their faculty people to come in.

I have received a number of letters from these faculty people at Oberlin which contains a complete chorus of applause for the National Science Foundation, and really urging that they have more of the same.

I think that is what we have heard here today. I think that is interesting because today we have heard administrators, and these letters I have are from faculty people, teachers, and they all echo pretty much the same point of view.

I am going to turn those letters over to you and to Phil Yeager on the chance that there is something in there that you might want to include in the report.

I was interested in President Dixon's very forthright confession that there is a certain lack of quality, lack of first-class teaching that is altogether too characteristic in the small colleges. President Sullivan also said something of the same sort. I suspect that this doesn't apply so much to the institutions that are represented here today as it does to some of the hundreds of other small colleges. But it certainly has impressed me that there is a dearth of real quality teaching, particularly as you said, President Dixon, in the physical sciences and increasingly so in the social sciences.

The limited supply is very real, and there is terrific competition with the bigger universities stealing the really good talent. It seems to me the most fruitful emphasis that the National Science Foundation could use in all of its programs is an emphasis on developing better quality teachers and teaching techniques. Of course, NSF has been doing this, but again I say more of the same is necessary.

President Dixon, you have emphasized the need for more effective and intimate relationships between the colleges and the National Science Foundation.

Now it seems to me, since there are so many colleges, to have more effective and intimate relationships, it requires an expansion of the National Science Foundation staff to a considerable degree. As an alternative to that, someone has suggested that the National Science Foundation might under contract to regional groups, college groups, work that way, rather than expanding its own staff. Do you see any advantage in that?

Dr. DIXON. I see advantages probably in both. I think that the notion of expanding the staff of Federal agencies is a fairly usual way at getting at a more complex problem, but the notion of whether or not undergraduate colleges could work together in consortia for the advancement of national policy and accomplishment of science is more novel.

There is the Associated Colleges of the Midwest that have developed a few effective relationships, particularly with large atomic

energy installations, with the Argonne Laboratory, and have joined together in certain fields of biology.

Mr. MOSHER. Antioch belongs to a new association?

Dr. DIXON. Antioch and Oberlin belong to the Great Lakes Colleges Association. We have had with the advice and assistance of the National Science Foundation, one exploration in this consortium of what we might do as a consortium that we could not do as individual institutions.

There seems to be two things we can do. As a consortium we could manage much more efficiently with the National Science Foundation on many of these internship programs. It would lend real economy and efficiency to the method of selection and support. And as a consortium we could, if we would waive our own sovereignties and recognize at any point of time that Oberlin might have the superior physics and Antioch the superior biology, we could ask the National Science Foundation to provide mobility to students that would permit them to move from campus to campus where we agreed that the programs had special elegance and need.

Mr. MOSHER. One other practical question, Mr. Chairman.

I believe one of the services that the National Science Foundation provides to the small colleges is helping to finance the purchase of the more sophisticated equipment and tools for scientific research.

As you increase your equipment and sophisticated tools, do you have a problem in the small college of hiring the technicians to keep those tools in operation? Is this becoming a practical problem at all?

I should think to make the best and most constant use of sophisticated machinery you might find it difficult to hire the technicians, in fact just cost of hiring technicians might become burdensome. Have any of you had that problem?

Dr. MCBRIDE. That is a very clear problem. That is one of the problems which ends in the college budget's increasing.

Mr. MOSHER. As a trustee of Oberlin this is the point I make.

Dr. DIXON. In response to this need one of the things which we do which is not necessarily decent in terms of education is to use undergraduates as technicians in the context of undergraduate research.

Mr. MOSHER. Is this a problem that NSF should give more consideration to and possibly help with?

Dr. MCBRIDE. I would put first some increase in some of the very good programs which are not large enough to go around—the instructional equipment program itself, the undergraduate research participation program. I think that comes first to my mind.

Mr. DADDARIO. Do you have a comment, Dr. Sullivan?

Dr. SULLIVAN. I just wanted to pick up one other aspect of the equipment program since it has been brought up.

For the undergraduate instructional equipment program, these grants are now on a 50-percent matching basis, that is, they provide 50 percent of the cost. There is a kind of competition within a college budget that arises from this. The cost of a piece of equipment that is purchased under a faculty project research grant may be paid for a hundred percent, it may also be useful for instruction, but the department and the college that asks for the instructional equipment for undergraduate work get a 50-percent grant.

Now it is very difficult to say, "No, we won't apply for that grant," it is a very attractive carrot, so to speak, but it does mean that the unrestricted funds of the college must be diverted in some cases.

Occasionally a special gift from a corporation or an individual will result from this carrot. But frequently, and as a continuing program, it is much more likely it will be a burden on the unrestricted funds of the colleges which are in very short supply. I think this might be given somewhat more attention also, as well as the cost of operating and maintaining equipment.

Dr. SAWYER. I would agree, Mr. Chairman, that Mr. Mosher has put his finger on a very real overhead cost that comes with the sophistication of science today, and, as we acquire this equipment, we are finding that we have to plan for technical help. It may be met through arrangements such as Dr. Sullivan spoke of where, by a relationship with industry in the area, there can be some helpful sharing of that cost, or by a moonlighting job arrangement with a technician there. But it is a cost, and I think it is the kind of help that the more generalized institutional grant that Dr. Dixon referred to could help institutions responsibly cope with.

Mr. DADDARIO. Dr. Dixon.

Dr. DIXON. I think this is related to this point. We have had some experience in the last few months in working with one of the so-called centers of excellence grants, and it is interesting to see what happens when you take an institution that tends to want to declare itself such as ours as being reasonably excellent and then ask the people of that institution what they would do to measure up to their own standard of quality. This is an internalized test. This isn't a test of having the university look at the undergraduate institution and saying what you would do.

Really it is staggering to those of us who administer the institutions to see what our faculties, who regard themselves as modest, would think it is necessary to have to produce undergraduate education in the sciences and social sciences in our time. I think they must be in considerable measure right, because after all they are the colleagues in the disciplines that set the standards.

If that is the case, our resources are vastly less than they should be to sustain this support. This runs through the whole gamut, this is physical facilities, this is supporting personnel, this is the teaching of teachers, this is the time for faculty research, this is the incorporation of undergraduate research into the undergraduate program.

Dr. SULLIVAN. And the library program.

Dr. DIXON. Yes.

I don't think I was wholly honest in response to your earlier question about regionalization—and if you let me use this private institutional experience to make my point—the genuine fear, I think, and it is a fear, that many existing liberal arts colleges have about regionalization is that this will increase specialization in the sciences and the social sciences as we move along in the social sciences, and will no longer permit good students to nominate themselves as students to the existing liberal arts colleges.

The fear is that when you confront this situation, as we are trying to confront it in the centers of excellence program, we will soon know the

gap is very great and we know if we were actually going to sustain this climate of wholeness that very significant expenditures must be made so that the status of the teacher in the liberal arts college who decides to teach physics in the liberal arts college as opposed to being a basic researcher in physics in the university is sufficiently strong, and he sees that that is importantly appropriate.

Our reason is not just a selfish reason, we want him to be capable— not just a social reason, it is simply that you cannot teach the humanities without the sciences, and you cannot teach the social sciences without the humanities.

If public policy is such as to draw away elegance of one group of disciplines in the national interest, it will, in effect, collapse the historic role of the liberal arts college. I think that needs to be said when one speaks about concern for regionalization.

Mr. DADDARIO. Mr. Mosher has underlined again the concern which has threaded itself throughout these hearings: It is much easier to come to a determination about quantity rather than quality, and the future quality will be extremely important. The denial of facilities such as these that have been raised by Mr. Mosher's question can seriously affect the quality we will have in the future.

It was mentioned yesterday that if we are to increase our research and development role to the point where it will be 4 percent of the gross national product as against the 3 percent today, it would mean an increase from $16 to $37 billion. We are going to need a lot of people of high quality to perform these functions.

Mr. MOSHER. I wonder if President Dixon is aware of the interest in the Congress for the creation of the National Humanities Foundation?

Dr. DIXON. Yes. And if history were to follow itself, it would put a further penalty on the liberal arts colleges by emphasizing first the quality of scholarship in the university and then second the quality of education in the liberal arts college.

Mr. DADDARIO. Mr. Davis.

Mr. DAVIS. Mr. Chairman, first I want to say that I think Dr. Atwood chose a particularly happy way of transferring his thought to the committee by selecting specific examples of boys who have become real specialists and who might well have been overlooked had it not been for the presence of Emory University in Georgia, and had it not been for the help of the National Science Foundation.

It happens that one of the boys you named is a constituent of mine, his father is a very old friend of mine. It proves that we have in all areas of our country the mental resources that we can't very well do without. We need resources, and we need to be assured that university facilities are available, and that these fine minds can be exposed to situations that will lead them to become specialists and to use those minds. I am glad you chose to give those examples for that reason.

There is one thing I wonder about. The point was made that in order to disseminate new scientific discoveries to the industrial sector, it would be a good idea to have seminars. I wonder if it wouldn't also be a good idea to have seminars between the large universities and the small ones, between the faculty members. Do you do such things as that, say, in Georgia, Dr. Atwood? Does Emory have seminars with the faculties of such colleges as Barry and Shorter?

Dr. ATWOOD. There is a rather specific answer to that in the case of our physics department. This is a participation program that involves contact with the secondary schools in the area. It is sponsored by the American Association of Physics Teachers for the State of Georgia. Professor Simons in our physics department is councilor for this, and through his efforts, working with the faculties of other colleges in the area, various high schools throughout the State are involved under a joint program. This had NSF support. New teaching methods in courses are part of it.

This kind of effort involves interuniversity support in a very significant way. I am sure you are familiar with the University Center in Georgia concept. It operates mainly in the Metropolitan Atlanta area. Again there are geographical limits as to how far we can go with this, but we are certainly pooling our resources wherever we can in this regard.

Mr. DADDARIO. Do you have a comment on that, Dr. Sullivan?

Dr. SULLIVAN. I tried to suggest both things. I think we can do somewhat more. In the past the main thrust of the institutes managed by many of our colleges, as well as the universities, has been toward improvement and upgrading of the secondary school teachers, but on occasion we have had two institutes during the summer for college teachers, one primarily in physics and another in inorganic chemistry, and the former was directed specifically at the college teachers in teacher training programs, for example, who had had a necessary minimum but still a minimum of direct science courses in their own training and are now ending up as science teachers, and I think a good deal more can be done in this way.

I think the help of a national organization like the Foundation would be very real in this respect. I think many of our faculty members are quite modest about putting themselves forward as capable of teaching all the other colleagues in the same discipline in neighboring colleges, but this can be overcome.

Mr. DAVIS. The following statement is in some material that the committee staff has prepared:

> Considering the urgent need for more technicians to improve the utilization of scientists and engineers, it may be desirable for small colleges to focus their funds and faculty on subprofessional training.

I do not mean to dwell unnecessarily on the State of Georgia, but it happens to have the educational system I am most familiar with. In my district there is a school known as Southern Tech. It is near Marietta, Ga., and its charter is to train technicians of subprofessional quality. I am unaware whether that approach is being used in other States or not, but I am sure that Dr. Atwood is familiar with that school.

Would you say that such a program is a threat to the future of small colleges or is it a welcome adjunct?

Dr. ATWOOD. It is a welcome adjunct in that most of us are not equipped to do it, nor does the faculty temperament want to do it. It is a different kind of a job, and it can be done best in an institution that is set up to do it.

The same kind of problem comes in the paramedical need that is being talked about so much in the country today. We are probably going to need specialized institutions to do that kind of training.

This in a way reflects back on the earlier comments of Congressman Roush when he accused us of not being typical, and I think we all accept that. I don't know how you quite can have five schools out of the hundreds of liberal arts colleges and get a true cross-section. I would say in effect we are a measure of the kind of sophistication that you can promote in the small liberal arts colleges. Most of us, in our modesty, would say that perhaps we are somewhat above the average, and in that sense we aren't typical. Part of the job of higher education in this country is to raise that average. Part of the reason that other schools have not taken advantage of the grants is indeed this degree of excellence, this degree of sophistication.

It is not a problem within my own institution. The total Federal funds that were available this last fiscal year amounted to nearly $6 million in our institution. It is true that a large percentage was for medicine and its research program, primarily from HEW. Our NSF funds amount to more than a third of a million. The reluctance of some schools to engage in this kind of effort is related to their lack of acquaintance with what is available and how that can help. That is not the problem among these five institutions, but it is a problem elsewhere.

Mr. DADDARIO. Dr. McBride?

Dr. MCBRIDE. In relation to Mr. Davis' question about technicians, I simply wanted to note that it was not only the specialized institution that Mr. Atwood mentioned that was going to work on this problem but the community college. In States in which community colleges are developing there are included in their broad programs a number of specialized programs for technicians.

Mr. DAVIS. Mr. Chairman, I have one final question.

In dealing with the National Science Foundation, do you find that you can live with the formula for the limitation of overhead, or do you have continuing problems in that area?

Dr. MCBRIDE. It is just like the weather, Mr. Chairman. We can live with it.

Mr. DAVIS. But you don't always enjoy it?

Dr. MCBRIDE. It is not entirely satisfactory.

Dr. SAWYER. To comment on that, I know some of the bigger institutions that have studied their costs more carefully put a much higher figure on overhead. As Miss McBride says, we live with this because it is helpful.

The overhead, including the visible kind of thing that Mr. Mosher spoke of, providing technical assistance, space needs, et cetera, as well as direct costs, clearly exceed the allowed overhead.

Mr. DADDARIO. Congress has taken action to eliminate this section in the appropriation acts. I think there will be an improvement, and we are anxious to see how the new legislative changes will affect this relationship. We hope it will allow for better flexibility and a better relationship.

Dr. SULLIVAN. I hope this can be pushed ahead in this Congress. Like the others, what we receive is inadequate, but it is better than not receiving any at all.

Mr. DADDARIO. The House Appropriations Committee has already taken steps in this direction. It is my understanding that the Senate

will follow suit. So we should have a different relationship, and one which I hope will be an improvement.

Mr. DAVIS. It was brought out by Dr. Wiesner, and it has been mentioned more than once this morning, that there exists a very bad need for computers. Does that mean that computers have turned out to be a tool with which the scientists find they can make much more rapid progress? Is that the meaning of the word "need" in that connection?

I ask this question because 18 years ago no one had ever heard of a computer.

Dr. MCBRIDE. There are two tremendous changes. One is in the range of problems that the scientist couldn't study at all if the computer hadn't existed. And two, there are ranges of problems that scientists won't have studied because they would have taken too much time. So the rapid advance of certain fields of science and certain fields not involved in sciences is one of the factors of present-day life. I think that the efforts made by several groups to estimate the future for computers are very important estimates.

Mr. DAVIS. Thank you.

Dr. SULLIVAN. I think I could add one or two points. One, I think there is a growing feeling on the part of many faculty members in science that not only their somehow personalized students majoring in science, but the generality of students in college, should become at least somewhat familiar with this new language as a problem that they are going to have as citizens.

And, secondly, I think in the hands of some faculty members, at least, this is not only helpful for research and for dealing with new problems, but it can be a fairly exciting tool for instruction, not only with college students, but we have had this experience this summer with a group of high school youngsters we are experimenting with on the campus.

Mr. DADDARIO. It has come to my attention that Vassar has arranged with IBM to use a computer at Schenectady during certain hours. I imagine thought has been given to this so that schools can get together and make arrangements to use computers in some form or another which will suit their needs.

Dr. SULLIVAN. This has been done quite rightly. Particularly for dealing with research programs, we are members of the Western Data Processing Center. But having some computer facilities on the campuses of these colleges also does something quite different in the direction of instruction—what you don't get quite over the telephone from Los Angeles to Portland, Oreg.

Mr. DADDARIO. Yesterday Dr. Wiesner brought out the point that computers, being so important, being such a tool to aid the quality of education, that the denial of their use could have a great effect. So I do agree, Dr. McBride, that the studies being made in this regard and how they can be used will be extremely important.

Mr. Brown?

Mr. BROWN. There has been during the course of these hearings considerable discussion with regard to balancing the program of the National Science Foundation insofar as relative support of the physical versus the social or environmental science. There seems to be no

question that the Foundation, as originally set up, had its primary emphasis in the physical sciences. There is a growing trend toward support of the social sciences. After all, they are still sciences. The question I would like to ask the panel is whether or not there needs to be an increasing attention to the support of basic research in the social and environmental sciences. I use this term in a broad sense.

Mr. DADDARIO. Would you like to start that off, Dr. Dixon?

Dr. DIXON. Yes, Mr. Chairman. It is a terribly complicated question, I think, because it carries in it all of this loading of relating the sciences and physical sciences to the social sciences and science. I suppose one of the ways to get at it would be to look at what a faculty in the social sciences would do with opportunity to extend their concerns, and one gets the impression that the social sciences are struggling not only with basic research, but they are struggling once again with what you would call applied research.

Anthropologists have begun to discover that we have also a contemporary culture, for instance, so that this can be studied. Contemporary data is being studied by the economists. So I think it is very hard in the social sciences to make this basic versus applied comparison. What social scientists seem to think they need are opportunities to invite young scholars at the undergraduate level into research, however defined, opportunities for support of their own scholarly objectives, however defined. And the one place where they seem to join with the physical science is on the question of hardware, on the point of computers that we were just discussing. They, too, want high capability for the analysis of random events as an element of their approach to basic research.

Mr. BROWN. We are talking about more than hardware, we are talking about fellowships, traineeships, faculty salary support, physical facility support—the whole range of NSF programs.

Dr. DIXON. There is one straw in the wind, and this must surely have come before this committee, and that is the effect that the changes in education in the sciences and social sciences now going on in the secondary schools are going to have on the undergraduates' education. This is now being seen, obviously, in mathematics, physics, biology—would not you say? We have not seen the emphasis of the changes in the social sciences at the secondary levels, which is going to make a very drastic change of the undergraduate curriculum in the social sciences, and is likely to step up the demands for support in undergraduate research, for instance, the social sciences at the undergraduate level.

Dr. SULLIVAN. And in college curriculum in these fields.

Dr. DIXON. And in college curriculum research in these fields.

Mr. BROWN. You haven't really hit the question head on, but let us continue. Maybe we will get some further suggestions.

The question, head on, is: Do you want to work in the direction of a program of an increasing level of support in these fields which are not getting the major attention at the present time by the National Science Foundation?

Dr. SULLIVAN. My answer to that would be that I think we should. I think there are two pitfalls. One is when asked a question like this, you are being asked either what proportion of additional support coming from the Foundation should go into this, or whether allocation

of present levels of support should be changed more in favor of the social sciences.

Mr. BROWN. Let me broaden the question. Really, we do not have to confine ourselves to the National Science Foundation. In the growth of the Federal support for education, we first had organizations such as the National Institutes of Health, in the health sciences, and much more recently the National Science Foundation aimed primarily at the physical sciences, but not entirely. We now have before this Congress a bill for an Arts and Humanities Foundation. Perhaps there is trend here for another foundation that would deal with the social and environmental sciences.

Dr. SULLIVAN. It surely is my general feeling that the social sciences have been starved, in this respect, in favor of the hard sciences—mathematics, physics, the health sciences, so I would welcome moves in this direction. And I think my own preference would be—and I am speaking highly personally—would be to continue this at least for a time within the National Science Foundation, rather than to move now to set up a separate agency for that purpose.

There is a second pitfall which I wanted to mention very briefly—and Dr. Sawyer is much better qualified on this than I am—and might conceivably disagree with me—but I think there is a tendency, I believe there is a view shared by some social scientists, that research and other activities in these fields would be most likely to receive support insofar as it essentially deals with highly quantifiable things, measurable things, and much of the most thoughtful research in these fields is not really of that character. I think that is generally the case. It is my impression, at least, that the philosophical kind of what I would still regard as research in these fields is especially undernourished and unlikely to receive support as much as the data collecting research will receive.

Mr. DADDARIO. Dr. Sawyer?

Dr. SAWYER. First, I think Mr. Brown's question is a good one, here, and in the long run I would guess there would probably be a case for increasing NSF or other funds in this area. But I think you have before you here, as representative in one sense of the colleges of the land, five battle-scarred veterans who are trying to meet science budgets that have risen sharply. The overhead costs for serious social science research are much lower. Some edges of it are needing computer time and similar things. The plant requirements and the technical requirements are typically less. They have also had a pretty good measure of private foundation support. It may be that private foundations will be less able to supply the need in the future.

In the area of social sciences, there are a lot more problematical issues, sensitive in terms of human reactions and emotional reactions. There might be more restraints on the freedom of such grants as to subject matter and directions of inquiry. If they were to be made, I think they ought to be in a form that was carefully devised, not to limit subject matter, either as an institutional grant——

Mr. BROWN. You are bringing up the political problems, which basically are the concern of the Congress, including the Federal role or presence in any field of education. It is a serious one. One needs to seriously consider it.

I am thinking in terms of the needs of the country as a whole, and not just the admitted large cost of research in the physical sciences. There is this whole problem of support for the graduate students, which is the same, both for the physical and the social science.

Dr. SAWYER. I think it is a question of the form. Very clearly looking ahead, not only are there needs for teacher training, for graduate fellowships, the kinds of institutes and summer programs that have been run here, but as somebody said, we know more about the molecule in outer space than we do about the social world we are living in, and very clearly a farsighted policy should anticipate increasing need of research funds for the social sciences.

Dr. ATWOOD. Perhaps it could be said that the colleges and the universities are more nearly competitive in the social sciences than they are in the physical sciences. This would lead me to second the comment made by President Sullivan that it would seem highly desirable for additional Federal support for social sciences to be made available through the National Science Foundation. This would probably tend to make such grants more the institutional type, rather than mission-oriented sorts that would come through a separate new agency that would, just by virtue of its being an institute of social sciences or a foundation of the social sciences, probably want to get problems solved.

Dr. DIXON. Now that you have opened the question, may I return, as there are one or two specific comments that I think one can make. The pressure in our kinds of colleges for the recruitment of the faculty in the social sciences is not as great as in the physical sciences. I think that can be stated, although it must be said at the same time that Dr. Sawyer's discipline, economics, is one of the scarcest of all disciplines—is one of the least reproductive, I might say, of all the disciplines. There are evidences of selective shortages in the social sciences, as there is in the physical sciences, but not at the same level. I think that is a clear fact.

Mr. BROWN. Isn't it true that to a very large extent this shortage in the physical sciences is one actually created by the Federal Government itself because of its support of the physical sciences in defense and atomic energy?

Dr. DIXON. I am not quite sure. Against that is the counterargument, which I might be permitted to use because my own field was medicine, the counterargument is the professionalism of the discipline that makes the difference. If you look at the physical sciences they are themselves trapped into a hierarchy of steps of training. You must move through this pattern for a long period of time in order to get through the profession. So it is not just the question of Federal research support making the competitive opportunity, but it is also the question of the professional behavior of disciplines in closing the entry to a discipline, and therefore holding the supply down.

Social sciences do far much less of this than the physical sciences, and the humanities do the least of all in terms of restricting entry.

Dr. SULLIVAN. On the other hand, sir, isn't there a good deal more concern about the number of years that the Ph. D. program is taking, first in the social sciences and secondly in the field of humanities, than is now true in the sciences? I think this support of the kind you are mentioning might help this problem.

Dr. DIXON. Do you think it might narrow the problem?

Dr. SULLIVAN. I think several things have worked on speeding this up in the sciences. One is the virtual availability of much more graduate fellowships, and the second has been the urgency of curriculum development, which has exerted its own pressure.

Mr. BROWN. I want to raise the philosophical problem here, not that Congress normally deals too much in philosophical problems, but the orientation of our society is unquestionably one of technology and physical science. This has resulted in the vast increase in GNP, and a vast widening of the gap technologically speaking between the advanced countries and the underdeveloped countries. This is a characteristic of our society.

However, I think we can raise the question, Is it necessarily a good characteristic? Perhaps we should be devoting our time and attention to this question of the quality of our culture in a broad sense, rather than merely the improvement of technology which is the basic thing that we are doing with the support of physical science?

Mr. DAVIS. Will the gentleman yield on that?

Mr. BROWN. Yes.

Mr. DAVIS. The problem that always strikes me about the social sciences is this: My colleague, Mr. Brown, just used the word "quality." It seems to me, you trap yourself quickly in the social sciences because it is so hard to keep from dealing in therepy as distinguished from basic research. Basic research assumes that you do not care what it is you find out, or what the result it. If you use a word like "quality," you automatically pigeonhole your research into either good or bad, and once you have done that you have prejudiced your efforts so much that it is no longer science.

This is what bothers me about the social sciences. For one thing, I don't know how you tell a good social scientist from a bad one.

Mr. BROWN. The question you raise is one of values, and I think it is only fair to point out that this is the most delicate the Congress can deal with. I personally feel we are on the verge of having a great deal of insight into the way human beings function in communities, insight that could be developed rapidly, that could be applied systematically, that could be contributory to the enhancement of human life. I am thinking not only in terms of the United States, but on a worldwide basis. It might be the most significant weapon that this country can have in terms of its role in the world, much more significant than another few billion dollars worth of atom bombs, for example.

If this is true, then we are neglecting the national interest in not furthering this.

Mr. DAVIS. I would agree with that.

Mr. DADDARIO. Any comment?

Dr. SULLIVAN. Applause.

Dr. SAWYER. Applause. I think that is right. I think the sense of the gap of our capacity to cope with this world and what we should reach for is most clearly visible in the sector you are talking about.

Dr. DIXON. Again, applause. It is a hard question to put to educators who say they are educating for the humane society—as to whether or not one gets at peace through mathematics or economics or whether one gets at peace through physics or anthropology. But

I would suppose there is only one answer, if the hypothesis is sound. there is only one way to discover whether it has any meaning; and that is try it. Beyond the point of speculation, it seems to me, one cannot get, unless one tries it.

Mr. BROWN. I think perhaps we have explored the problem enough, Mr. Chairman.

Mr. DADDARIO. It is always good to end on a note of applause, Mr. Brown.

Mr. BROWN. I suppose.

Mr. DADDARIO. Mr. Conable?

Mr. CONABLE. I think there is a certain amount of pessimism implicit in the democratic process, and we are in an area that we could talk all day about, our ability as a democracy to instill this kind of value.

Let's come to something more specific. I am concerned about the mechanics of your contacts with the National Science Foundation. Apparently there are a number of schools which are not having a very extensive or very happy relationship with the National Science Foundation.

I assume that most of you have had, for the most part, fruitful contact with the National Science Foundation and, therefore, you are not inclined to be critical of the administration of the National Science Foundation. The administration does become a matter of substance on occasion.

I wonder if you have any specific suggestions on ways in which the National Science Foundation can reach out to include a greater part of the colleges in the country. I am concerned with their relationship to colleges and universities, of course, and not anything else. This is something perhaps we are going to get into, Mr. Chairman, but I would like to get the reaction of this group on this specific question.

For instance, does NSF come to you, or do you go to them? If they do not come to you, should they?

Mr. DADDARIO. Dr. Atwood?

Dr. ATWOOD. We have touched on this and perhaps we could stress it by saying that it ought to be more of a two-way street. Now everybody is coming to Washington and being the supplicant. It would be a better stature, a better position, if the Federal Government were in part selling its wares, if it were out looking for good customers. This might be done by the establishment of regional educational offices of the Foundation.

Mr. DADDARIO. Following Dr. Sullivan's observation?

Dr. ATWOOD. Yes; a man in an area becomes the knowledge man, the contact man, the source of information about the Foundation, making it more accessible. Such regional representatives could assist with the difficult problem of allocating, to be sure that you do have not just a few proposals before you that happen to have been there but rather all the proposals that might possibly come from any source.

Mr. CONABLE. It is a matter of your coming to Washington generally?

Dr. ATWOOD. We commute.

Dr. SAWYER. If I could pick up this comment, I would feel that the problem was in some sense less NSF than the total Federal structure.

I think where the small college feels lost most often is where else might it have applied or where parallel programs might be submitted.

Most of us know about NSF and NIH, but then someone will mention the real place for this is over in HEW. Here we are not knowledgeable, at least very few of us are.

I thought the suggestion that Dr. Sullivan made was good—a possible central roster and information office, possibly then with regional offices, where you could come with your problem or area of interest and you could find where the various programs in the total Federal establishment might be sources of support.

Mr. Conable. I assume all of you also deal with other Federal agencies. Are your relations with the National Science Foundation as felicitous as they might be with the other agencies, or do the other agencies handle their contacts with the universities in a different way?

Dr. Sullivan. I think there is some variety of this kind. I would myself think our experience in this respect with the National Science Foundation is probably at the top of the list.

Mr. Conable. That is the sort of thing I am interested in hearing. We are, of course, studying the National Science Foundation.

Dr. Sullivan. Not to subtract from my earlier suggestion, my own impression is the National Science Foundation has done a pretty good job of informing the colleges of what its own programs are, not only by publications but also by field visits and by regional conferences. I know we have played host to a couple of these where neighboring colleges send faculty members to a conference that was of an informational character. So my suggestion stems from the increasingly complex problem of all the agencies overlapping more from than any criticism of the job that NSF has done by itself.

Mr. Conable. This is not a problem that is peculiar to universities I might add. Almost everyone who deals with the Government seems to have this sort of problem.

Dr. Dixon. I would add to what Mr. Sullivan has said and say this, in the range of Federal agencies with which the small colleges deal, the National Science Foundation seems to have a much greater appreciation of the context of getting at science within the organized setting of education and places an emphasis on the relevancy of the context without I think denying the importance of the discipline. Whereas many agencies put the emphasis on the discipline to be served whether or not it distorts the context in which the service is given. We regard this as of course very creative administration.

Mr. Conable. I would like to ask one more question.

In relation to teacher training, which is an area of major concern, do you have any suggestions beyond expansion of the internship program generally?

The National Science Foundation has a very successful teacher institute program with respect to the high school teachers. It has reached a great many high school faculties and has apparently had a noticeable effect on the quality of the instruction of high school students in the physical sciences. These students are entering colleges now, and it is all going for naught unless, having had their interest stimulated, their needs can be met on the college level. So this is a matter of concern in the National Science Foundation I am sure. I

would like to have further ideas you might have about the specifics of a program to instruct teachers for colleges and universities.

Dr. ATWOOD. If you asked a sampling of educators across the country what was the most valuable program of the National Science Foundation, you would probably find there is quite a consensus that it has been the teacher training program.

This is because of the profound upgrading that we have all seen in science and mathematics training in large numbers of high schools, high schools that we had thought were almost beyond recall, or needed such drastic help. It has been brought about very rapidly and on a very wide scale.

The reason we can say this is because this has such long-range effects on development of science throughout the country. It is the feeding mechanism, and we can see the next wave of this coming in terms of a thrust forward that could not have come in any other way.

Mr. DADDARIO. Any other comment?

Dr. SULLIVAN. I might add one quite speculative sort of thing. I don't at the moment see what part the Science Foundation should play in this, but we have recently been through a long debate of a couple of years on the extent to which our college should move further into graduate work.

In the course of that we invited as consultants several people from the universities who had the characteristics of having had experience at the undergraduate level but who now were primarily concerned with the administration of graduate school departments. And one of the suggestions we received from them, more than once, was that a new kind of graduate degree that would have the respectability of a Ph. D. but not as much emphasis on individualized research competence, as usually is the case in this degree, is very badly needed.

It is now the case that we have this one degree in our fields of knowledge, it does emphasize research, it purports to predict that the holder of that degree will engage in research, when we know that a good many of them become much more teachers than researchers.

Some change was recommended in these several cases. I would be out of order to try to give very much of a personal judgment on their suggestion because we don't have that kind of experience. It was an intriguing suggestion. I was interested that it came to us, for example, from both the head of a biology department in a university and the head of a romance languages department in a university.

Dr. DIXON. There is probably a range of novel relationships between undergraduate colleges of the sort represented here and universities that could perhaps be used to construct novel Ph. D. programs of the sort that Dr. Sullivan is talking about that would make the recruitment of teachers more practical.

You asked directly I think whether there was a need for the upgrading of college teachers in the sciences.

Mr. CONABLE. I am assuming there is.

Dr. DIXON. I expect this is so. I expect in the hierarchy of the institutions we have to ask the universities to do it for the colleges in the same sense that we ask the colleges to do it for the secondary schools.

Dr. MCBRIDE. Mr. Chairman, Mr. Conable's question, though raises another point, and an important one. The young teacher well

prepared by his graduate work who then goes to a college will not keep up his enthusiasm and competence unless he has some possibility for further research in the college where he is teaching. So that one of the important programs would be one which would help the young research man who has very little as yet to show for his work but has sufficiently strong recommendations, so that it is worth giving him a start.

Mr. DADDARIO. Any further comment?

Mr. CONABLE. No.

Mr. DADDARIO. Dr. Sullivan, in your preliminary remarks you referred to the fact that Congress has in the case of the National Science Foundation provided an administrative flexibility which you think is both unusual and good, and you favor it. You have said where restrictions exist you oppose them. What do you have in mind?

Dr. SULLIVAN. One we have already discussed a little bit, that is the State quota for fellowships. I think that is undesirable, as I mentioned earlier.

Another, as I understand it, is a provision that a certain amount of dollars or a proportion of the total budget, as the case may be, must go into certain programs or a collection of certain programs. This again limits the flexibility of the Foundation.

I believe that restriction has applied most recently—that kind of restriction—to provision that a minimum amount of funds and quite a large percentage of the total budget should go into secondary—particularly secondary school teacher training programs. If the Foundation did not have this restriction, it and its advisory committees together might reach somewhat different conclusions—a little less might go there or a little more into another sector as needs change. These kinds of restrictions on the freedom of the best judgment professionally that can be brought to bear is what I had in mind.

Mr. DADDARIO. This brings out the point which Mr. Roush raised, that by having this flexibility, you have less central control and more autonomy within the schools, and it makes the National Science Foundation's program more attractive.

Dr. SULLIVAN. Whether that is a guaranteed result or not, it is at least more probable.

Mr. DADDARIO. Dr. Sullivan, you said that you consider the biggest problem to be in the area of teaching the undergraduates. Would you expand upon that?

Dr. SULLIVAN. I think when you group together the problems of quality and quantity it is pretty clear that the institutions most favorably situated to compete for, to attract, and retain the best prospective—not only the present but the prospective—teachers and researchers in science are the graduate schools and universities, where there are lower teaching loads and more chance to be a scientist per se rather than a teacher of science.

Second, I think some institutions like those represented here that have acquired some prestige, that have a certain hospitableness for research combined with undergraduate teaching will be able to attract and retain some faculty members that perhaps other institutions would not.

You get down lower on the totem pole, when you think of the job to be done at a level of college teaching which is in the introduc-

tory years, roughly the first 2 years. Because where this is the emphasis the teacher does not have, even if he likes that kind of work, the additional and important satisfaction of working with somewhat more advanced students.

From the point of view of attracting the ablest scientists and retaining them, this is lowest on the totem pole, I think. It is also the need when you move from quality to quantity which quantitatively is the most haunting one, because the freedom of movement from the high schools into our total collection of collegiate institutions, including an increasing number of juniors and community colleges, is much the greatest there.

Much larger numbers are entering the first and second years of our total collegiate structure than are entering the third and fourth years. So, again, the number of teachers required is very considerable, and it is the combination of the qualitative attractions and the quantitative problem that made me select that particular group of teachers.

Dr. SAWYER. Mr. Chairman, there is one restriction which was implicit in a good deal of our comment this morning, and that is I think NSF is constrained on the amount of funds that it has available for science in the undergraduate college.

There are certain programs with ceilings on them, equipment and research participation and direct grants, for instance, for physical plant and equipment are limited, and I think the need is pressing very strongly at those limits.

Mr. DADDARIO. You raised the specific point in regard to a program that was turned down because of lack of funds.

Dr. SAWYER. A new science center which had had an encouraging reception by the staff. Then the Congress a year or so ago had to reduce the amount available for new programs, requiring NSF to stay with existing programs, and one of the new programs had been a program for assistance in the construction of undergraduate facilities.

If your question had that wide a swing, I wanted to enter that thought.

Mr. DADDARIO. I wondered if Dr. Sullivan's remarks were wide enough to cover programs such as that. I think you indicate that you do include such programs.

Dr. SULLIVAN. Yes.

Mr. DADDARIO. Mr. Vivian.

Mr. VIVIAN. I have one question relating specifically to the NSF relationship to small colleges, and then I would like to switch to a somewhat different subject.

Reference was made earlier by Dr. Dixon to one of the several midwest associations. Would you identify it again?

Dr. DIXON. One is the Associated Colleges of the Midwest and the other is the Great Lakes Colleges Association.

Mr. VIVIAN. There is a third one which is primarily active among the Big Ten schools.

Dr. DIXON. There are others I am sure.

Mr. VIVIAN. I would like to ask you the following question: Suppose that the National Science Foundation had available to it a certain quantity of funds which could be given to regional organizations of small schools, do you think that organization would have difficulty in deciding within itself a simple allocation?

Dr. DIXON. May I answer directly—but I will have to answer by analogy, because we have not had the experience in science. We have had the experience in the humanities and in the social sciences under the auspices of private foundation grants which were designed to encourage exploration in non-Western cultures. These are, in a sense, coercive grants that are designed to make you perform in a way you are not performing.

My direct knowledge of the work of the Great Lakes College Association is this has worked superbly, that they have invented new ways by which to arrive at their decisions, they have invented new ways by which the faculties may join in making these delicate judgments of quality, because this program also includes the expenditure of moneys for research, and they have laid themselves open to the institutional changes that come from the expenditure of money.

So I think the answer would be there is some experience that indicates that if these associations could be granted some of the autonomies of subfoundations—if you want to put it in those terms—they could make some creative explorations of policy.

Mr. VIVIAN. I bring up the question for two reasons: The first reason reflects on a question I raised the other day with the head of a science department of one of our great universities, and a very, very competent man, and I was asking him about the question of distribution and the amount of funds which he had in his department from various sources. It turns out that most of these funds are Defense Department funds. I indicated that we were considering the question as to whether a larger fraction, approaching one-half of the total support for science in the universities, might not well come from the National Science Foundation, rather than one-eighth as it does now.

He was somewhat reluctant to see this because he felt within his own department that stresses and antagonism would arise, which now are handled by each faculty member going to Washington and soliciting the interest in the large bureaucracies here.

Do you think the situation prevails in the smaller colleges?

Dr. DIXON. Certainly not with the same intensities. The sense of allegiance of the faculty member to the institution rather than his discipline is greater in the small college than in the university. The opportunity to undertake change on a collegewide basis is greater.

Mr. VIVIAN. Supposing, for example, the National Science Foundation had, say, $30 million available for regional organizations of the smaller colleges, and this was divided in some equitable way across the United States. Then the question was asked of the presidents of all the colleges in the areas, would you prefer that we administer this from Washington or would you prefer that we administer this through regional compacts of the colleges themselves? What do you think the comments would be?

Dr. DIXON. I think it would vary. I think that colleges that had some experience with the capabilities of working through consortia would probably prefer the consortia rather than working with Washington, whereas colleges that had no experience working together might fear working together as colleges as much as they would with Washington.

Mr. VIVIAN. In other words, there would not be any clear indication as to which way such funds would be parceled out?

Dr. DIXON. I think it would probably have to be talked through and negotiated in each instance.

Mr. VIVIAN. Would this apply to staff projects, facilities, computers, and the other matters mentioned today almost equally?

Dr. DIXON. Do you mean would the agreements be greater on some matters than others?

Mr. VIVIAN. Yes.

Dr. DIXON. Probably. As has been said here, almost all of the colleges of the sort here represented are beginning to consider that a computer is as important as a library. When it becomes that common, you have kind of a common understanding that is different than the common understanding about the importance of having a faculty that can do basic research in physics.

Mr. VIVIAN. Supposing funds were made available either from NSF or from the Department of Commerce for projects directed principally toward improving the economic base of the Midwest or the Southeast by support through the smaller colleges. This then reaches to the smaller communities as well as the smaller colleges. Do you think the smaller colleges would have any reluctance to engage in a cooperative venture of this kind?

Dr. DIXON. There would be a wide variety of interest. I can think of many colleges that would not reject the proposal on intellectual grounds but would not care to divert their energy.

I can think of others, our own experience is the experience of being the center of the development of industry and technology in the Lower Miami Valley. You would clearly find some institutions that would be delighted. I would think these would be the institutions that saw themselves as having a closer and closer association with metropolitan areas in urban centers.

Mr. VIVIAN. If this should be done, it should be done with those who wish to come on a completely voluntary basis.

Dr. DIXON. I think that would get the widest participation.

Dr. ATWOOD. The metropolitan idea is rather critical here.

Mr. VIVIAN. I was making specific reference to the Southeast. Those of us in the Midwest, as the chairman well knows, have been pressing for better distribution of research funds to the Midwest, but I think the Southeast might stress it more.

It does not mean that you do not have places like Huntsville, but it does not permeate as well to your small cities and towns. You are probably more deficient in that than any other part of the Nation.

It is rather humorous to see you people labeled as the presidents of small colleges. Your accomplishments are great. I know this well from having dealt with you in the past, and as a student, getting a degree from a small college in Schenectady. I have three small colleges in my district, and another community college, there, being started, and I have a feeling that small colleges as such are simply evaporating away.

The teacher colleges grow very quickly in my State to factors-of-10 increases in size. What was known as Ypsilanti Normal College has now become Eastern State University, with 11,000 students at the present time.

I am curious to know whether or not the number of small colleges is stable, increasing or decreasing, and I exclude community colleges specifically. Do you know the answer to that question?

Dr. ATWOOD. It is slightly increasing. You find interests in various parts of the country, again of denominational groups, wondering if they can start a new college.

Mr. VIVIAN. Of principally a religious structure, is that correct?

Dr. ATWOOD. At the moment, in Atlanta, the Baptists don't have a college, and they have bought land on the northeast throughway, and they are trying to get started. I shudder to think of the problems they face in starting a new college today, but they think there is an educational need.

Mr. DADDARIO. Mr. Sullivan?

Dr. SULLIVAN. I am not sure this is really more than a footnote, but I think this kind of question almost needs to be dealt with partially in terms of history and what scale one is using and using the adjective "small" and so on, because it was the case not very many years ago that a small college tended to be of 600, 500, or 400. Now a small college tends to be one of 1,500, 1,100, 1,000, 900, and projecting ahead, I think it won't be—myself, I don't think it will be so very many days or years before it will be thought that a small college is an institution of 2,000 or so. The pressures economically on many of the existing institutions that have been quite small have been to expand to support an adequate range of faculty competence, to avoid a one-man department in some fields.

Many of the new institutions, at least I have the impression, are aiming toward this newer scale, rather than the older one, which many people have kept in mind as the desirable small college scale.

Finally, I think there is an enormous difference between the privately supported and the publicly supported colleges, as I am sure you are aware, in this respect. The pressures to expand on what have been small public institutions have been far greater than the pressures to expand on the independent colleges.

Mr. VIVIAN. I ask this question because in my own district we have 45,000 college students. It is 11 percent of the total population. We have one large university, the University of Michigan, with 40,000 students. It is scaled now to maintain any activity which a university has, but it is also so large that the students have rather difficult sociological problems, and we are trying to break the university down, going back to the scale I knew when I was an undergraduate going to college.

This has proved very difficult. We have one new church college, Concordia, a very excellent one. Two cities really need a college, and one has just gotten a community college. The problem there is it may have difficulty in taking on the scope of activities that a full 4-year college should be able to handle, and may be as much a hazard as a help. The other city does not happen to have a community college base, and the religious groups have not become interested.

I am curious to know, is there a vacuum here? In other words, is it very difficult to start a college at the 2,000 person level?

Dr. SULLIVAN. It is much harder to start a college than to kill it, I think. I suspect this should be kept in mind. I have the impression—Dr. Dixon might contribute to this, because I think some of the public regional universities in Ohio have attempted to cope with this by setting up local extension divisions, manned both by visitors and by resident faculty in communities such as I think you are describing. Isn't this the case, in places like Chillicothe, Ohio University?

Dr. DIXON. What Dr. Sullivan refers to is sort of a hybridization between the universities and community public funds, in which public funds extend the universities. It does not wholly answer the question you are speaking to because you are talking about, I think, the autonomous liberal arts college that has the maximum of academic freedom, the maximum of intellectual freedom in its makeup. I think the data are quite clear. Small liberal arts colleges are growing at the slowest pace of all the institutions in the educational hierarchy.

The principal problem in their replication is the capital funds for their construction. We note this in the recent publicity concerning the new Hampshire College. We have studied this in our college, and we are wholly convinced that we could replicate if we wanted to have undergraduate colleges of this sort if it were possible to capitalize the physical plant. There is sufficient affluence, and there are sufficient ways for those who are not affluence-supported by public moneys for education. We are reaching the point where the levels of tuition will support a responsible level of quality, but the characteristic device by which the private colleges have been created is by the private donation of capital, and this clearly is wholly insufficient if one were to have a new spirit of growth in the private colleges.

Mr. VIVIAN. In other words, the conditions for the formation of private colleges, except for religious organizations, are no longer very satisfactory?

Dr. DIXON. That is right, and particularly the condition of the capital financing, which has constantly become much more costly.

Mr. VIVIAN. Your comment about the growth of public institutions, which I think is quite correct, is that they will probably grow very rapidly. The chances are the only colleges left then in the small-college bracket in the next 10 years will be the private institutions supported by religious funds, which are small and growing very slowly, but because of the capital problem, with virtually no new input unless the churches take this on as a goal.

Dr. DIXON. This may be well an honest definition of the situation.

Mr. DADDARIO. Mr. Yeager?

Mr. YEAGER. Mr. Chairman, I would like to direct this question to Dr. Dixon, who spoke about the possibility of a new type of institutional grant perhaps being made available by the Foundation.

How would this differ from the developmental grant which NSF is now in the process of developing?

Dr. DIXON. It would use the experiences of the developmental grant as the basic experience to extend support to a larger group of institutions. It ought, I think, to be a grant, as the developmental grant, that doesn't make sharp distinctions between capital funds and operating funds. What would be needed, however, is to develop some rather elegant devices of accountability of institutions. The present devel-

opment grant is based on the narrow band of high quality reaching for higher quality and you can get the scientific community to help you significantly in making that distinction.

I would suggest that we couldn't afford to limit ourselves just to that band, that we have to go down below that and support potential for improvement—a rather more risky investment.

Mr. YEAGER. Well, the purpose would be roughly the same?

Dr. DIXON. The purpose I think would be roughly the same and the operation might at least be based upon the experience previously gained.

Mr. YEAGER. Several people have mentioned the difficulty of acquiring good science faculties. Could you give me what you think is the main reason for this? Is it the teacher load that Dr. Sawyer spoke of? Is it salary, the equipment, or the stimulation of other colleagues? What is the major reason, in your view, for this problem, if there is a problem?

Dr. ATWOOD. Perhaps it is a combination of all these things. Certainly each of those elements would come into individual circumstances. I would turn it around and ask what can we do to help. It seems to me the kind of institutional development funds that would do the most for upgrading this faculty might be relatively free—what we might call starter grants. It is for the young professor, who has finished his Ph. D., beginning to teach, but not yet able to come to AEC or DOD or any of the other agencies with a firm proposal. Some of us are using our own funds for this purpose, but NSF funds could help in this regard very much.

Mr. DADDARIO. Any further comment on that?

Dr. MCBRIDE. One further factor, even though you have six or eight factors there, seems to me to be the fact that sciences are expanding so rapidly that the very small department isn't adequate in its spread, isn't adequate in its range.

One of the most important reasons for the increase in the size of the smaller college is the increase in the faculty and its range of competence. It really isn't based on a student population problem at all. So we have I think in the sciences in many of our colleges been extending the number on the faculty, and as we do, we have a better chance of bringing people to the department, because the young person sees that it is a department in which he can work with colleagues who are important to him.

Dr. SULLIVAN. I have perhaps a couple of relevant comments. I referred earlier to our use of some university consultants in helping us to solve some of our complexities about going ahead with graduate work.

One of the most ominous things that they reported to us was the extraordinary number of Ph. D.'s at the time of finishing work in the graduate department that identify themselves as prospective members of university faculties rather than college faculties. This is true of a number of different disciplines.

I think the strengthening in the colleges of both the reality and with it the vision that the undergraduate student could have of a strong science program going on in the college would help to carry over toward some greater influence on careers.

The other comment is with the younger faculty members particularly in mind, we have used some of our institutional funds to provide very small summer grants as extra compensation to those young faculty members who wished to pursue a summer program and did not have any outside research grant. This has been extremely well received by our faculty.

We are also agreed in principle that something approaching a very early sabbatical program will be very much in order and we will follow it once we can find funds for it. This is after a couple of years of full-time teaching, the young man has a chance to have applied in the classroom some of what he has learned in the graduate school, this has changed somewhat his research ideas, and yet he is not in a position to compete for research grants, or simply to consolidate these different experiences he has had in the graduate school plus first-year college teaching. Some of the universities that are better financed are doing this and I think this gives them greater advantage in recruiting.

Mr. DADDARIO. I expected, of course, that this Panel would make a great contribution to the work of this committee. But the ideas which have been proposed, and the avenues of opportunity which have developed here today have been far beyond that which I could have expected. I regret, on the one hand, having kept you here so long, but we could not have let you go without taking full advantage of your presence. I want to thank you and to compliment you for your help to this committee.

Dr. MCBRIDE. Mr. Chairman, may we thank you for your very interesting problems and for the very generous time we have had in expressing our point of view.

Dr. ATWOOD. Also, for your willingness to let us represent the small colleges here.

Mr. DADDARIO. This committee will adjourn until August 19 at 10 a.m.

(Whereupon, at 1:12 p.m., the subcommittee was adjourned until Thursday, August 19, 1965, at 10 a.m.)

NATIONAL SCIENCE FOUNDATION

THURSDAY, AUGUST 19, 1965

HOUSE OF REPRESENTATIVES,
COMMITTEE ON SCIENCE AND ASTRONAUTICS,
SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT,
Washington, D.C.

The subcommittee met at 10:20 a.m., in room 2325, Rayburn House Office Building, Washington, D.C., Hon. Emilio Q. Daddario (chairman of the subcommittee) presiding.

Mr. DADDARIO. The meeting will come to order.

We began these hearings on June 23, with an outstanding witness, Dr. Haworth, who is now, in accordance with our original plan, our closing witness.

We are extremely happy to have you before us again, Dr. Haworth. We also want to thank you for responding so quickly to the series of questions we submitted to you some weeks ago.

We are anxious to hear you.

STATEMENT OF DR. LELAND J. HAWORTH, DIRECTOR, NATIONAL SCIENCE FOUNDATION

Dr. HAWORTH. Thank you, Mr. Chairman.

I understand the main purpose of this session is for you to be able to bring up questions that have occurred to you since I appeared before, either because you have thought of new subjects or because other witnesses have brought up things that you may wish to question me about. But I would ask your indulgence for a few minutes to make two or three particular points now, and then, if I may, I would like to have about 5 minutes at the end of the session to make a closing statement, if you will.

Mr. DADDARIO. You take as much time as you like, Dr. Haworth.

Dr. HAWORTH. Thank you.

First, I should like to respond to your remarks about the answers to the questions by taking this opportunity to say something more general, and that is that the work of preparing the answers to these questions, and of preparing the charts and so forth that lead to my original testimony was, of course, done by the staff. I want to say that I have never seen a staff respond more nobly than the NSF staff has done for these hearings.

I would especially like to pay tribute to Dr. Bowen Dees, who has led the effort and done it, I think, very, very well. I would also like to express my gratitude publicly to you, to the other members of the committee and to the other persons who have appeared before you.

51-204—65—vol. 1——49

Mr. DADDARIO. Well, I appreciate hearing that. I can very well understand how much staff work there has been in this.

I would also like to add that Dr. Dees has been helpful to the committee all through these hearings, and he was especially prominent during the seminar on scientific and technical manpower. We would like to add our note of thanks for his participation.

Dr. HAWORTH. Thank you, Mr. Chairman.

There are three factual matters that I would like to call to your attention today, because in one form or another, they have come up during the hearings.

First, there has been displayed, throughout the hearings, a great interest in the social sciences and the Foundation's support of the social sciences. It has been said correctly that we started late in the social sciences, and that we have tried to expand our efforts in them—expand them, in fact, more rapidly, relatively, than in other fields.

In this connection I would like to call your attention to the answer given to question A(6), particularly to the chart that goes with the answer to that question, in which there is an attempt to show the relative growth in the social sciences compared to the others. And, incidentally, in engineering, too. We simply normalized, as scientists would say, at the year 1960, which, incidentally, was the first year in which NSF gave multimillion-dollar support to the social sciences. The numbers at the left of the chart are indices of the relative support in succeeding years. And, as you can see, whereas the average support for all basic research project grants has gone up since 1960 by a factor of about 2.5, the support of the social sciences has gone up by about 6.6.

Now, NSF support of social sciences is still small. These are relative numbers, of course. I wouldn't make any claim that our support of the social sciences is large. But I do want to call your attention to the fact that we are definitely interested in the social sciences and want to press forward in their support.

The second matter is the support of fellowships in engineering. I sent you, Mr. Chairman, a copy of a letter from me to Dr. Augustus Kinzel. Dr. Kinzel has been under the impression that there was very little NSF support for graduate students in engineering. This was a mistaken impression, and I attempted to show this in my letter to him. I wrote Dr. Kinzel that his information was not complete. A briefer version of the letter has been handed to the subcommittee staff and I would like to call your attention to two or three points.

The first point is that in the totality of what we call "fellowships," the ratio of success of the engineers—that is, the number of engineers that are awarded fellowships as a fraction of the ones that apply, is just almost exactly equal to the average: Including all kinds of fellowships, 24.7 percent of the engineers that applied received fellowships; and the average for the Foundation was 24.3. In other words, there is no discrimination for or against the engineers, and there shouldn't be, because, of course, we do award these fellowships on merit, without relationship to field.

If it turned out that we could award 1,000 fellowships, and the best of the 1,000 were mostly chemists or biologists, or whatever, then they would get the fellowships. That could result from what the National Science Foundation Act tells us to do. But it doesn't

turn out that most of the fellowships go to one field. They are pretty well distributed.

This is even more impressive in terms of numbers when we look at the totality of the fellowships and the traineeships—they are all devoted to the same purpose—and the distribution there is also widespread.

The second, somewhat more complicated table shows that situation. Here I am talking only about the predoctoral fellows. (The figures I gave before included fellowships for teachers and postdoctoral fellowships and senior faculty fellowships and so forth.) The second table is for graduate students, and you can see on the right-hand column what the situation is with reference to the traineeships. You can see in the left-hand column the total situation.

Now, these figures can't be exactly precise, because the case of some of the traineeships, the institution is free, although we specify the field for many of the traineeships, there are some that are given to the institution to distribute as it wishes. However, as well as we can judge, of the awards this year, about 40 percent of the total predoctoral fellowships and traineeships will go to engineers. This compares with the fact that about 31 percent of all graduate students are engineers. In other words, at the moment, if anything, the engineers are getting more than a proportionate number of such awards.

Now, this will change downward somewhat over the next couple of years, because the fact that it is so high is affected by the fact that we started the traineeship program first in engineering. We have made traineeship awards for 2 years in engineering, for only 1 year in the physical sciences and mathematics, and not at all, yet, in the biological and social sciences. We will do the latter this coming spring.

So the 40 percent of all fellowships and traineeships that now goes to engineers will not be maintained at that level. My guess is it will drop to about 30 percent—that is, in proportion to the number of graduate students in engineering.

I should point out that to simply say 31 percent of the graduate students are engineers somewhat overstates the case. The figure includes both full-time and part-time graduate students, and a far larger fraction of the graduate student engineers are part time than are those in physics, chemistry, biology, and so on. This is because a great many engineers who have jobs in industry attend school part time, and this is much more prevalent among engineers than among others.

So, I merely wanted to emphasize to this subcommittee that there is certainly, in my opinion, no failure on the part of the National Science Foundation to recognize the need for student support among the engineers.

Mr. Daddario. Was there a difference here, because Dr. Kinzel was making a comparison with engineers as against all of the other sciences?

Dr. Haworth. That may well be part of it.

Mr. Daddario. My recollection of his testimony is that he was making a comparison in that sense. If that is so, is there any validity to that argument? Wouldn't it change the percentages?

Dr. Haworth. Well, Dr. Kinzel called me a day or two ago, after he got my letter. By the way, he is a very good friend of mine; there is no battle here.

I think he does have somewhat that feeling, that there is engineering and there is science, and he tends to compare engineering with all sciences.

I think that I would say that if one wants to draw a parallel, one could say there are the physical sciences on the one hand and engineering on the other; the biological sciences and the health professions; the social sciences—what one might call the "social engineers," although they are all included in the term "social scientists." Actually no term has been applied to the "social engineers," but there is an analog, of course. There are those who work in the more theoretical and basic aspects and then those who apply the social sciences.

But even if one draws such an analogy, I don't think one can say that there ought to be more engineers than physical scientists, or more physical scientists than engineers. It happens that if you group all these together in the graduate schools, a bit less than a third are engineers.

Mr. DADDARIO. If we had someone testify for the mathematical sciences, they could perhaps make the same kind of comparison?

Dr. HAWORTH. Perhaps so.

Now, then, the third matter that I wanted particularly to touch on today resulted from a remark of Dr. Grobman's, and again, I want to set the record straight, lest you get a false impression that we are going to get rich on royalties.

Dr. Grobman made the statement——

Mr. DADDARIO. We were interested, not that NSF is getting rich, but that if you were getting any royalties, at all.

Dr. HAWORTH. Well, this was just an off-hand remark of Dr. Grobman's, and I thought maybe I had better give the actual numbers.

Dr. Grobman made the remark that about $1 million had been received by BSCS and returned to the Treasury. Actually, the situation is that about one-half million dollars has been received in royalties and returned to the Treasury. It is a little less than that—about $480,000, something like that.

Undoubtedly, what Dr. Grobman had in mind about the other half million was that we allowed BSCS, as we have some of the other projects, to print extra copies of preliminary books that they used in their trial runs, and then sell those at cost.

As you know, the groups that are doing the curriculum studies prepare preliminary texts, then try them out at high schools, for example, that are interested in trying the new curriculum; schools volunteer, and are furnished free the texts that they are going to use. This is in return for their cooperation in doing the trial runs. And so there is a large printing of each preliminary book.

But there were, in this case and in some other cases, many requests from schools that weren't taking part in the trial run, that for one reason or another wanted copies of these texts. So we allowed BSCS to print, as I say, extra copies, and then simply sell them at cost. That is really not a return, of course, in the sense that the royalties are.

From all the projects, about $2 million has been returned to the Treasury, and there is another roughly $1 million, held in escrow by the various projects, that is returnable.

The BSCS project of which Dr. Grobman, of course, is speaking, is doing very well on royalties. For example, $151,000 was returned for the second quarter of this year. When you put all the projects together—and they are at different stages, so some haven't reached the stage of getting any royalties yet—there will be a substantial sum of money returned to the Treasury. But it is, of course, going to be a long way from repaying the cost of the curriculum studies. It never was expected that royalties would repay the cost.

Of course, in time, the royalties will drop off as the results of the curriculum work get out into the commercial channels.

Well, that concludes the special things I wanted to say, and I am at your disposal to answer any questions that you may have.

Mr. DADDARIO. Mr. Yeager.

Mr. YEAGER. Mr. Chairman, before we proceed, on the subject of the support of graduate education in engineering, I wonder if we might have this statement incorporated in the record.

Mr. DADDARIO. Without objection, it is so ordered.

(The statement referred to is as follows:)

NSF SUPPORT OF GRADUATE EDUCATION IN ENGINEERING

I should like now to furnish you some data concerning the Foundation's support of fellowships and traineeships in engineering, about which there was some discussion earlier in this hearing, specifically on July 15.

Since the beginning of the Foundation's fellowship program we have made it clear that engineering students were eligible to apply for predoctoral and postdoctoral fellowships in any area of training offered in engineering schools anywhere. All along we have had substantial numbers of engineering applicants and the number of awards made in engineering—in comparison with the number of applications—has been roughly the same as in other major classifications. In fiscal year 1965 our records show that the distribution of fellowship applicants and awards by field was as follows:

Field	Applicants	Awards	Awards as percent of applicants
Engineering	3,120	772	24.7
Mathematical sciences	3,595	1,017	28.3
Physical sciences	6,837	1,688	24.7
Life sciences	3,650	810	22.2
Social sciences	3,252	693	21.3
General science	85	13	15.3
Total	20,539	4,993	24.3

This table refers to all of our "fellowship" programs for American citizens, including the secondary school teacher fellowship program in which we make no awards in engineering. It does not include our graduate traineeship program, however.

If we now look at the support offered to graduate students through our graduate and cooperative graduate fellowship programs and through the NSF graduate traineeship program (from a second table which follows), it will be noted that NSF support to engineering students, due in considerable measure to the graduate traineeship program, is now at an exceptionally high level: we estimate that 40 percent of the predoctoral students the Foundation will support in academic year 1965–66 (from fiscal year 1965 funds) will be in engineering—at an estimated cost of $12.4 million of the $31 million obligated for the support of graduate students in all fields. Our percentage of support in engineering is higher by a substantial margin than the fraction (31 percent) of all science and engineering graduate students who are enrolled as students of engineering.

Distribution of predoctoral fellowships and traineeships by field, fiscal year 1965

	Total	Graduate fellowships			Cooperative graduate fellowships			Graduate traineeships
		Applicants	Awards [1]	Awards as percent of applicants	Applicants	Awards [1]	Awards as percent of applicants	Traineeships [2]
Engineering	[3] 2,399	1,235	273	22.1	1,276	296	23.2	1,830
Mathematical sciences	932	1,497	386	25.8	834	236	28.3	310
Physical sciences	1,727	2,629	643	24.4	2,013	440	21.9	644
Life sciences	453	1,476	343	23.2	724	110	15.2	....
Social sciences	431	1,571	289	18.4	741	142	19.2	....
Total	5,942	8,408	1,934	23.0	5,588	1,224	21.9	2,784

[1] Fellowships awarded to individuals by the National Science Foundation.
[2] Traineeships awarded to institutions and departments within institutions; selection of individuals is the sole responsibility of the institution.
The assignment of the 2,784 traineeships by field in fiscal year 1965 is based on the following assumptions: (a) that the 925 continuing traineeships will continue to be utilized in engineering departments (as they were in fiscal year 1964); and (b) that, of the 1,859 new traineeships, 905 will be in engineering, 310 in mathematics, and 644 in the physical sciences. It should be noted that the graduate traineeship program in fiscal year 1965 did not include life and social sciences.
[3] In addition to the estimated 2,399 in engineering in these 3 programs, 213 individuals were offered other fellowship support in engineering, bringing to a total an estimated 2,612 awards in engineering in fiscal year 1965.

I believe these data show that the Foundation is providing substantial support for engineering students and for more advanced engineers through its fellowship and traineeship programs. In fact, the data I have cited seem to me to show that NSF support of graduate students in engineering is at a level which should make engineers feel they are doing very well indeed.

In earlier testimony it has been suggested that it would be useful for the Foundation to assign a few fellowships to the general area of engineering design as a possible method of encouraging more students to work on theses of this nature instead of working on dissertations more appropriate for a doctor of science degree. The Foundation has to date maintained a position that the details of advising graduate students with respect to their field of specialization and the manner in which they should pursue their work is primarily a matter for decision by the university authorities where the students study.

For NSF to set a quota on the number of fellowship awards which it would make in a given field in terms of the type of dissertation that the students should undertake would be very close in our judgment to creating a mechanism by means of which undue influence could be correctly charged to NSF—that is to say, we could then be accused of interfering in the types of decisions which are more properly within the purview of the universities and colleges.

This is not to say that NSF is uninterested in the question which has been raised. We are currently supporting two major studies under the aegis of the American Society for Engineering Education on the basic question of the shape of things to come in engineering education: one of these studies is under the direction of Dean Joseph M. Pettit at Stanford University and concerns itself with graduate education in engineering: the other is under Dean George A. Hawkins at Purdue, and is concerned with undergraduate education. We hope that these two studies will be useful in helping to move those who are concerned with improving engineering education in the direction of creating a curriculum and all of the necessary relevant educational devices which will in fact make possible the type of special education for engineers which is most appropriate for the coming decades.

Mr. YEAGER. I have one question in regard to the above table, Dr. Haworth.

Dr. HAWORTH. Of that statement?

Mr. YEAGER. Yes, sir. You list there the graduate fellowships, cooperative graduate fellowships, and graduate traineeships. In

regard to the latter two, could you describe for us what the situation is there? Are these somewhat similar, and do you intend to keep this arrangement going as between the cooperative and the traineeships?

Dr. HAWORTH. Well, in the first place, you understand what the "regular" graduate fellowships are; they are awarded to people who apply directly to the NSF. They are evaluated; awardees are chosen. They then are free to go to whatever university they wish to attend.

At the other extreme, the graduate traineeships result from grants given directly to the universities on the basis of their proposals and competition. But the competition here is between universities, or more strictly, between the departments of universities. A university will propose that they be granted so many traineeships in the electrical engineering department, so many traineeships in the physics department, and so forth and so on. We then evaluate those through our panel system, and finally give awards to the university, spelling out that we have awarded so many in each of these subjects.

We also give some to the institution to distribute as they wish, and we allow some flexibility in the distribution, even of the ones that we have designated as to fields or departments.

But the heart of the traineeships program is that the universities are entirely responsible for selecting the awardees. They don't submit any names to us or anything of that sort. In other words, it is a grant to the university to be used for traineeships.

The "cooperative fellowships" are sort of in between. Here, individuals apply through their universities, through the university that they are either attending or plan to attend. A given man will apply to a given university, asking that the university, in turn, forward to us his application for a fellowship, for him to attend that university. In other words, he is selecting in advance the university that he will attend.

The universities, then, rate the applications that they have. They forward them to us, and then they are put through a rating system similar to that applied to the applicants for the regular graduate fellowships. We then select the number that we can award. So it is a national competition, but it is a national competition in which the applicant has already chosen his university.

Now, this was done in a deliberate step toward wider distribution of the fellowships than had occurred from the regular graduate fellowships, because what tended to happen, of course, was that once a fellow got an NSF fellowship, he wanted to go to one of about half a dozen universities. And there was a big concentration of NSF fellows in those universities.

On the other hand, the recipients of cooperative fellowships have spread out much more widely, and, of course, the recipients of traineeships more widely yet.

The first year of the traineeship program we awarded traineeships to, I think, 107 universities, which was within a very few of the total that give Ph. D.'s in some branch of engineering, which was the criterion for eligibility that first year.

This year we extended the traineeship program to the physical sciences and mathematics, and I believe 167 universities received awards. This year the criterion was that they must give a Ph. D.

in some one of the subjects that we covered—such as physics, or mathematics, or chemistry or engineering. This 167 includes virtually every university that gives Ph. D.'s, so we got a really wide distribution by virtue of these traineeships.

Now, in answer to the second part of your question, although there is not a formal decision, yet since the Science Board must consider it, we plan to omit the cooperative graduate fellowships and increase the number of regular graduate fellows and the number of graduate trainees. This is, in large measure, for administrative simplicity, both for us and for the universities; to have three kinds of what amount to graduate fellowships is getting a little complicated. So we plan to award no new co-op fellowships next year.

There are, however, 2-year awards. That is, a man is selected for 2 years but he is actually given his fellowship for only one, and the second year is dependent on having done successful work. If the university certifies that he has done successful work, he gets a second year automatically. Of course, those commitments or obligations will be carried ahead into the following year, but we will add no new cooperative graduate fellowships.

However, I should repeat that the Science Board has not yet formally endorsed this change.

Mr. YEAGER. This would not necessarily mean a reduction in the total support of this program though?

Dr. HAWORTH. No. As I say, we will distribute these among both the regular fellows and the traineeships.

Mr. YEAGER. Thank you.

Mr. DADDARIO. Mr. Davis, do you have a question?

Mr. DAVIS. Yes, thank you, Mr. Chairman.

Dr. Haworth, at the outset, I would just like to take this opportunity to express my appreciation for the work that you and your staff put into responding to the requests of this committee for information that we specified. These hearings certainly have been an enlightening experience for me, and I feel sure that this sentiment is shared by all the members of this subcommittee.

In that connection, it is well to remember that the committees of Congress who examine a particular question are usually looked to by the remaining membership of Congress to explain the situation to them, and I think that much benefit will accrue from these hearings.

There was one question that I wanted to ask, in the light of a discussion that we had during an executive session which occurred last Tuesday.

I made the remark that the organic act creating the National Science Foundation was so broad that you could go forward with such projects as Mohole, the Antarctic program, atmospheric research at NCAR, and many other things without the necessity of further authorizing legislation.

Now, question A–12 touches upon this point. In replying to that question, you review some of your experiences as a member of the Atomic Energy Commission, and you mention certain benefits which did accrue to the AEC and to Congress and the country, I might add, from the fact that the AEC had to have authorizing legislation.

I would be most interested to know your views as to whether or not you think that a similar authorization procedure would be beneficial to the National Science Foundation?

I might add, too, that in our discussion it was brought out that it may have been possible, within the purview of NSF's charter, to place many of NASA's activities under the National Science Foundation. A lunar probe is actually not too much different from a probe of the earth's crust as in Mohole. It is an effort to further our scientific knowledge.

Of course, this was not done. This committee was created primarily, I feel sure, to handle the authorizing legislation for our national space program. Since that time this committee has had a good bit of experience authorizing individual programs and going over NASA's budgetary items with a fine-tooth comb, so to speak.

I would be most interested to know your comments as respects more detailed authorizing legislation with respect to the programs of NSF.

Dr. HAWORTH. Well, first, Mr. Davis, let me thank you for your opening remarks, and then I will try to comment.

As I tried to say in my answer to the subcommittee's question, I really have had no experience with authorizing legislation, except in the sense that while I was a Commissioner at AEC, the Commission had authorizing legislation for its major facilities, for reactors, big accelerators, new laboratories, new production units, things of that sort. So I have had no experience whatsoever with authorizing legislation for a general program.

I was at the Commission only 2 years, but my observation was this: The real virtue of the interaction between the Commission and the Joint Committee on Atomic Energy—and I appeared many, many times before the Joint Committee on all sorts of things, from weapons to test bans, to high energy physics and so on—the important thing was that there was an interchange of information through the hearings that the Joint Committee held. They never had one, while I was there, that was analogous to the one that is just finishing here, that went through the whole spectrum of the Atomic Energy Commission's activities, but they had, each year, a number of hearings that went in depth into some phases of the program; it might be the civilian nuclear power program, it might be the program for nuclear power in space—reactors, or isotope energy generators for NASA's and the Air Force's space vehicles—or it might be on high energy physics. There was one such hearing just recently, in May, I think, that I took part in.

Those hearings were unquestionably of great value to the Commission, and from where I sat, it seemed to me they must have been of very great value to Congress. So this kind of hearing has a reciprocal value, I think, to both the legislative and executive branches.

Now, whether there is additional virtue in having such exchanges between Members of Congress and representatives of an executive agency focus around a particular authorization for a particular activity, I just don't know. I don't have any experience to bear on that.

This is especially so because the one aspect that the Commission did have authorization hearings on, namely big and expensive facilities—the Foundation doesn't have very much of. The Foundation's

support is more diffuse; except for NCAR and the two observatories we don't have any things that compare to the AEC's national laboratories or to the big production facilities at Hanford and Oak Ridge and Paducah and Savannah River and so on. Ours is a more widespread, small project type of activity. So I have no basis for really answering the question of whether hearings would be more or less valuable if centered around authorizing legislation. But I do say, with great conviction, that penetrating hearings in depth, on the various aspects of an agency's programs are a good thing.

Mr. DAVIS. Thank you. I believe that pretty well answers my question.

I think you would agree that it is a question that would be deserving of scrutiny?

Dr. HAWORTH. Yes, certainly.

Mr. DAVIS. Thank you, Mr. Chairman.

Mr. DADDARIO. Dr. Haworth, during the course of these hearings we have had some discussion about the National Science Board and its relationship to you, the Director. There were suggestions that the National Science Board have a full-time Chairman, and also that it have a staff of its own.

I have received a letter from Dr. Houston, who is a member of the Board, and in reference to the staff he says this:

> The staff of the Foundation is quite small when one considers the amount of money they must disburse in relatively small packages. On the other hand, the National Science Board has no provisional staff at all. The Director has always been most helpful in providing members of his staff to work for the Board, but the fact that their permanent assignments are on the Director's staff makes it difficult for points of view to be developed apart from those of the Director. Since the two Directors of the Foundation have been men for whom the Board has had the greatest respect, relations have been most amicable. But possible alternative policies may not always have come to the attention of the Board, but have been resolved on the staff, instead.

I would like your comment on that statement, and especially the idea that the alternative policies may not have had the opportunity to receive the attenion that perhaps they should have, if that is in fact the case.

Dr. HAWORTH. In the first place, let me say, I believe—I now speak quite frankly—I believe this would be a mistake, because I think we could have the possibility of two National Science Foundations if you try to separate the Board and its staff from the Director and his staff. And this would be a step in that direction.

However, let me then comment on the hypothetical point that Dr. Houston makes. I have not observed, in my brief tenure as Director any instances where the pro's and con's and the alternatives have not been fully presented to the Board by the Foundation staff.

I will not say that I and my staff have thought of every idea, every conceivable idea. Certainly we haven't. I would think if there were any virtue to having staff people who devoted their full attention to the Board, it would simply be that more people might have more ideas. But I don't see that that function requires that staff people available to the Board be divorced from the regular Foundation staff. It merely means that they should be assigned more time to think of the matters of interest to the Board.

In other words, my feeling would be a difference of degree, rather than of kind.

Mr. DADDARIO. You feel that the improvement in this relationship lies in the suggestion that you have made; not that the staff ought to be separate, but that it be beefed up somewhat and given a greater opportunity to work on the problems brought before the National Science Board?

Dr. HAWORTH. Yes. And we mustn't forget that the National Science Foundation is defined as the Board and the Director, and the Director is a member of the Board, and I just don't see—I just don't believe we should try to tear that apart. It has been a working entity that I think should remain.

Mr. DADDARIO. Then you feel that it becomes a question of further development of the idea that staff ought to be enlarged, but not necessarily separate and apart?

Dr. HAWORTH. Yes, that would be my feeling about that aspect of it.

Mr. DADDARIO. There also has been some discussion that the National Science Board should be just an advisory board. In this same letter there is another reference to that point, which I would like to read, and ask your comment about:

> I believe it is important that the National Science Board retain its present authority. One reason is that it gives the members of the Board a feeling of greater responsibility than would a purely advisory capacity. It permits the President to appoint members of greater stature, and it gives the scientific community a feeling that the Board, which to some extent represents them, can have some significant influence upon the policies, at least of the Foundation, itself.

Dr. HAWORTH. Well, I think this is a question of judgment, and it is very difficult to know which is the better way. I, of course, responded to your question B(1) on this and pointed out that at the present time in the statute there are a couple of difficulties. I think those difficulties could probably be resolved.

The first one, I certainly don't know how to resolve, but I think the real pro and con arguments go something like this:

The points that Dr. Houston makes are certainly good points, and I don't think there is any way to predict—or to assay, would be a better word—how much responsibility a board would feel, if it were advisory. I would point out that I don't know of any group that feels more responsibility than the President's Science Advisory Committee, which is advisory, and certainly the distinction of the members of that is very great, and their devotion is very great.

I personally feel that it doesn't make a great deal of difference, either way. There is this hypothetical chance that I mentioned in my answer to question B(1) that the Director would be caught in a difference of opinion between the Board on the one hand and the administration or the Congress on the other hand, and the statute, of course, gives the Board the power to make the policies of the National Science Foundation.

Now, actually, the Board, insofar as my observation has been concerned, fully recognizes the practical fact that the National Science Foundation, including the Board, has to work within the framework of the policy of the Government, but literally speaking, the act doesn't say that. So there is this hypothetical possibility.

Then there is, of course, the practical question that I also mentioned, that the Board meets only every couple of months. There are day-to-day decisions that have to be made that sometimes are difficult to make, and this is especially true in the realm of policy. Here it becomes a question of where do you draw the line and say "This is operation," and "That is policy"?

I say this because, as we all know, there is some policy in every action, and there is some action in every policy, at least a little in each case.

So it depends on how one defines policy.

The Board has delegated to the Director the power to carry out nearly all operational actions. There are some—I think it is something like 50—decisions each year on major grants and so on that still are beyond the power of the Director to decide, but as to those major ones, the time element is not likely to be too important.

The Board, however, does not have the power, even if it wanted to, to delegate policy even to its own executive committee, let alone the Director. So there are problems that arise in that connection.

Now, those are the difficulties with the present situation, and I suppose one would say are the arguments and reasons for making the Board advisory.

On the other hand, there are points such as those Dr. Houston has made. I think there is also the question of how the scientific and academic communities would feel about making the Board advisory, whether this would result in any less assurance on their part, is a psychological question that I can't answer.

Probably the scientific community feels more assurance than if the Board were only advisory. Certainly some individuals do. But how great that feeling is, I have no idea.

Finally, back on the other side, there is the other point that I made in my answer to your question; namely that although the act does not require that the Board adhere to governmental policy or go along with it in its public utterances the fact, of course, is that it does so. Hence some people have made the point that if the Board were advisory, it would be in a better position, on the one hand to question actions or policies it found itself in disagreement with, and, on the other hand, perhaps to give greater vocal support in the public sense to things it believed in, with respect to the Foundation and the entire governmental science structure, without being accused of being prejudiced. In other words, if they didn't have the responsibility and the authority, they wouldn't have quite so much feeling of reluctance about being proponents, so to speak. Now, again, I have no assessment of how important this is, but in reality, there have never been any of the kinds of serious problems that I said are theoretically possible. Both Dr. Waterman and I, as far as I know, have always been in accord with the Board.

There has been give and take on both sides, of course, when views were different, but everything has been amicable and there has always been a final consensus in which the Director and the Board would agree.

(The text of the letter from Dr. Houston follows:)

RICE UNIVERSITY,
Houston, Tex., August 16, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development,
House Committee on Science and Astronautics,
Washington, D.C.

(Attention Mr. Philip B. Yeager).

DEAR MR. DADDARIO: Dr. Eric Walker, Chairman of the National Science Board, has sent to the members of the Board copies of your letter of August 9 enclosing the 19 questions your committee submitted to him after his testimony on July 27. Since it appeared impracticable to convene the Board, or to get a significant concensus, he suggested that some of us might be willing to write you our personal views on some of the questions.

I must especially emphasize that the views expressed below are mine alone, but they are views based on almost 12 years as a member of this Board. The comments are numbered to correspond with your questions.

(1) The National Science Board is, I believe, unique in that a certain limited amount of authority is conferred on it by statute. It is possible that this authority has not been exercised as vigorously as might have been, but in any case such authority can extend only to the activities of the National Science Foundation itself. The Board can influence other agencies only through persuasion or through the Office of the President.

(2) The rather rigid connection between the system of divisional committees and the internal organization of the Foundation staff, although provided in the original act, possibly went somewhat beyond the conscious intent of the authors. The suggested reorganization provides a flexibility such that the divisional committee structure, as well as the staff organization, can be rapidly adjusted to the changing obligations of the Foundation.

(3) I doubt if the Foundation should have greater operational authority. Its peculiar function, and the area in which I believe it has been the most valuable, is in the support of small scale basic research in a wide variety of places and institutions.

I can remember that during the 1930's the Government operated scientific laboratories, at least in the physical sciences, were not highly regarded by the scientific community in the field of basic research. Among the reasons for this was that, in the field of basic research, originality is more important than experience. A research laboratory starts out with an enthusiastic staff and they all grow old together. In a university, the continuing influx of new students can produce a steady stream of new ideas. Most of them are bad, but they can be evaluated by the senior people. Government and industrial laboratories are now attempting to provide similar conditions, but it is not easy.

During the Second World War the idea of contract research in universities was developed to remedy the deficiencies felt in the Government laboratories. At the end of the war, efforts were made to perpetuate the scheme through the Office of Naval Research, the Research and Development Board, and then through the National Science Foundation. The Foundation has been most effective in this aspect of its work.

It must be emphasized again, that the above comments refer only to basic research. Work in applied research and engineering may very well be done in institutions devoted to such research and engineering only.

(7) I believe it is important that the National Science Board retain its present authority. One reason is that it gives the members of the Board a feeling of greater responsibility than would a purely advisory capacity. It permits the President to appoint members of greater stature and it gives the scientific community a feeling that the Board, which to some extent represents them, can have some significant influence upon the policies, at least of the Foundation itself.

(9) The staff of the Foundation is quite small when one considers the amount of money they must disburse, in relatively small packages.

On the other hand, the National Science Board has no professional staff at all. The Director has always been most helpful in providing members of his staff to do work for the Board, but the fact that their permanent assignments are on the

Director's staff makes it difficult for points of view to be developed apart from those of the Director. Since the two directors of the Foundation have been men for whom the Board has had the greatest respect, relations have been most amicable, but possible alternative policies may not always have come to the attention of the Board but have been resolved in the staff instead.

In conclusion may I express the gratitude which I feel as a member of the Board for the effective way in which your committee is studying our operations.

Very truly yours,

W. V. HOUSTON,
Member of the National Science Board.

Mr. DADDARIO. Mr. Roush.

Mr. ROUSH. Dr. Haworth, I am not real sure that this is a fair question to ask, but the question is prompted by an experience I had a few years ago. I serve on the board of trustees of a small college in northern Indiana, and this college was seeking its north central regional accreditation. In the process of seeking this, we had to go through a period of self-criticism and writing a report which actually was the result of our own self-study of weaknesses, and our potential, and our strengths.

As a result of this we learned a great deal about ourselves and the school was strengthened because of it.

I would imagine that because of your coming in relatively new, into this position as Director, that the Foundation has done the same thing. I would also imagine that because of these hearings that you have examined yourself very carefully. I think it is apparent from this report which we have before us, which is a response to the questions the committee had. I wonder, as a result of that, if you have discovered, shall we say "weaknesses" or "inadequacies" or any policies which should be changed, administrative processes which should be changed, which have not come to the attention of this committee?

Dr. HAWORTH. Well, first, let me say that you are quite right on your first two statements; one, that we are constantly analyzing ourselves, and we have, as I told you in my first appearances, not only a constant look at ourselves in the sense that a staff always does, but we have two mechanisms that have been set up since I came to the Foundation to do this. One of them is what we call the Planning Council, which consists of myself as chairman, the deputy director, the associate directors, and equivalent, we use the term "associate director" only in the substantive parts of the program, but the Comptroller, for example, is one member of the Planning Council, the General Counsel is a member and, the administrative manager, who is responsible for all the administrative activities of the Foundation, is a member. The Planning Council does a great deal of the sort of analysis that you are talking about.

In addition to the Planning Council, we have a planning staff under Dr. Dees, who is the Foundation's Associate Director for Planning. Dr. Dees' organization has two branches in addition to the Office of Economic and Manpower Studies. One is the Office of Program Development and Analysis, which is responsible for the internal planning of the Foundation; and the other is the Office of Science Resources Planning, which is responsible for planning in terms of NSF's responsibilities with respect to the totality of the national program in science.

In making this effort to strengthen NSF's organization for planning I was not motivated by a feeling that anything was particularly wrong with earlier Foundation planning efforts. It is more a ques-

tion of, "Here we are, where do we go from now on to improve the situation?"

In some instances we have tried to simplify things, because some of the administrative methods, for example, that were appropriate to a small organization become unwieldy when they are applied to a big organization. On the other hand, planning of the science development program which was under discussion but not crystalized when I came to the Foundation, has resulted from this kind of organized thinking.

We are giving a great deal of thought now to what ought to be our future long-range role in science education, particularly in view of the great upsurge of interest in the country as a whole, led by the President and the Congress, and, of course, the Office of Education.

Now, the second statement you made, Mr. Chairman, has made it so I need speak only 4 minutes at the end, instead of 5. I wanted to say, as you have pointed out, that this hearing has contributed very greatly to our turning our eyes inward on ourselves and trying to think hard about where we are going and what we are doing.

It shouldn't be true, but it is true that most organizations are likely to take a thorough look at themselves and come up with new ideas only when something happens to prod them into doing it. And it is also very true—and this is an observation that I made originally during the war—that it helps a great deal to have to write things down as we wrote down the answers to your subcommittee's questions. During World War II, I was at the radiation laboratory at MIT which developed microwave radar. The laboratory started from nothing and had 4,000 people by the end of the war. It happened that after the Japanese surrendered, I remained on for about 6 months to help write the report of microwave radar during World War II. And I remember remarking to Dr. DuBridge that I had more good technical ideas while I was writing my part of this report than I had during the entire war, and that I thought there ought to be, in the next war, an understanding that every 6 months we would stop for a month and write, because it forces one to assembly his thinking.

And this hearing in addition to the virtues of our exchange of ideas orally, has forced us to do a great deal of thinking, because some of the things that were pretty nebulous in our mind, had to be put down fairly precisely in answer to your questions.

Mr. Roush. I think we would be glad to hear any new ideas that developed as a result of writing this.

Dr. Haworth. I don't think we have reached the point of forming any new, brilliant ideas. But we have certainly realized that there were many things that we had to focus on and try to do more about.

The discussions of the social sciences, of how science is to play a stronger role in what I will call the problems of society, and the question of geographic distribution of science resources and support. The geographic distribution problem wasn't new to us, but we have some different impressions about it, perhaps, than we had. But I don't think there have been any brilliant new ideas.

Mr. Roush. Well, perhaps some have been conceived which are still in the embryo stage, and some day will make their entry, then——

Dr. Haworth. I am sure that is so.

Mr. Roush (continuing). Into the world of open thinking.

Dr. HAWORTH. Of course, ideas of this kind can't be identified quite as concretely as technical ideas about radar.

Mr. ROUSH. That is all, Mr. Chairman.

Mr. DADDARIO. Mr. Mosher.

Mr. MOSHER. Thank you, Mr. Chairman.

Mr. Davis referred to the breadth of your charter. I have been curious to know whether you sometimes feel vulnerable because of its breadth. Do you sometimes wish that it might be more precisely stated in limiting terms? Would there be any cause for us to consider legislation which would limit it?

Dr. HAWORTH. No.

Mr. MOSHER. For example, are you glad that you have Project Mohole? Would you welcome legislation which would take projects of that sort and put them in some other agency?

Dr. HAWORTH. I would have to confess, facetiously, that there have been times when I wished that Mohole had been started, so that I could crawl into it.

Mr. MOSHER. Seriously, does that belong in your purview; this is what I am asking.

Dr. HAWORTH. I think so.

My answer to your general question is that I think the broad charter, that the Foundation has, has been a very fine thing. I think Congress was very wise to write it that way, and I would hate to see it be restricted in any sense.

You see, these things like Mohole are permissive. The law directs us to do research, that is to support research—we don't do research—to support research and support science education and so on, but the directives in it are in very general terms, so that if it seemed inappropriate for us to do a particular thing, such as Mohole, there is nothing that forces us to. And, of course, the flexibility allows for a great deal of give and take between us and the other agencies. Here I would like to rephrase something that we have tendered to say and that other people have tendered to say about that.

There has been a good deal said to the effect that the National Science Foundation is sort of a gap filler or a balance wheel or something of that sort. I would rather say it the other way around—and this is one kind of thinking that has grown out of these discussions, incidentally, that Mr. Roush referred to—I would rather think of it the other way around; that the Science Foundation has a responsibility to see that the scientific health of the country is good. And I think that one should say, one can say, that this is a mission. It has two facets, one the support of research and one the support of education, but the scientific health of the country is really the Foundation's mission.

Now I would rather describe NSF's relationship with the basic research and support of education of other agencies by saying that we should take every advantage of what they can do, rather than by saying, "We are going to be here as a sort of service of supply and they are going to be the fighting troops; we are going to be the reserves and just fill in the gaps where they appear in the line." I think we should be in the forefront, but we should take account of all the capabilities and support that the other agencies can give and are giving, rather than say we are just the fillers-in.

Mr. MOSHER. Now you say that you did not have to take on Mohole, that it was not forced upon you. But I can see where in the national interest an increasing number of major engineering projects have to be done. When I suggest that you might feel vulnerable, increasingly Congress might be pushing onto you a lot of these big engineering problems and projects. Would you feel vulnerable in that respect?

Dr. HAWORTH. Well, I would like to make a distinction here, and that is that while Mohole, in its present phase, is a big engineering project, that phase has as its objective the providing of some facilities to do some basic research. It is analogous to building a big accelerator or big radiotelescope or other things of that sort.

I do not think it would be appropriate for the National Science Foundation to go into an engineering development such as the Mohole platform and drilling equipment, except as a means to the end of doing basic research. But the act, you see, doesn't provide for our doing that sort of engineering development. The avoidance of this sort of thing is, to my mind, one of the reasons why we have to be cautious about getting into applied research. For just the reason you mentioned.

Mr. MOSHER. Thank you.

Mr. DADDARIO. Dr. Haworth, to follow up Mr. Mosher's question—and I think he has an extremely good point—you get involved in an operation such as Mohole, and, as Mr. Davis has already suggested, perhaps if there had been authorization control this might have been looked at more closely.

We have now reached the point where we are talking about the expenditure of $110 million for Project Mohole. This is far above what was originally estimated. One must also look to the value of Mohole as against other programs that you might support. Isn't it then a stringent requirement on all of us to look into this aspect of NSF's activities? Should it, in fact, get involved in programs of such vast depth? Doesn't it reach the point where it will have a weakening influence on your other activities?

I think this follows closely with Mr. Mosher's concern.

Dr. HAWORTH. Yes, sir. I would like to make, if I may, Mr. Chairman, a couple of specific remarks about Mohole, and then discuss the question more generally.

You mentioned $110 million. Now I think of this in quite a different way.

Mr. DADDARIO. I am just using your figures.

Dr. HAWORTH. I know, but this is because I am asked for figures. I like to think of it in the following way: As I said in partial answer to Mr. Mosher, the present phase of the project is to provide some facilities for doing deep drilling under the ocean. Now, part of the objective of that deep drilling is to penetrate into the mantle of the earth, but that is only part. And to say that the Mohole project is going to cost $110 million or whatever it might be, up to the time that one does penetrate the mantle once, I think is not really the right way to look at it.

One should say, how much does it cost to get these facilities into being? Our present estimate of that, incidentally, is somewhere between $75 and $80 million. That is, to have done all the research and development that is necessary to develop this kind of facility, to con-

51-204—65—vol. 1——50

struct the platform and the drilling equipment, to make the site surveys, to know where we are going to go first to drill, and so forth. Then we will go drill. We won't even try initially to drill as deeply as the mantle. We will drill half a dozen or eight or whatever, or even more, maybe, holes to lesser depths. Then at some point we will go to one place; namely, as we see it now, off Hawaii and sit there for 2, 2½ years, something like that, trying to drill a very deep hole to the Moho. But when that is done, that is only the beginning.

In other words, in one sense to say that the Mohole project will cost $110 million is saying too much; and, in another sense, it is saying too little, because I am sure this equipment will be used for years and years and years to do other drilling. There may possibly be no need to drill more than one hole to the mantle, but there certainly will be need to drill lesser holes around various places in the ocean.

It is analogous to the big accelerator that the Lawrence Radiation Laboratory built at Berkeley starting in the late 1940's. One of the things that we had in mind—I say "we" because it was a concerted program of the AEC to build two big accelerators, one of which was built at Brookhaven, where I was, and one at Berkeley. Brookhaven was a new laboratory and didn't have much of a staff at that time. It was decided that we should build the smaller one—still very big, compared to anything that had been built—and that the Radiation Laboratory, should build one of six or eight or whatever billion electron volts.

Now, in order to get, to be able to create negative protons, we knew that one must have an energy of at least 5.6 Bev, billion electronic volts. So it was decided between the two laboratories and the AEC and the AEC's General Advisory Committee that the Berkeley machine would be at 6 billion volts, so it would be safely over the threshold required to make negative protons. But it never was called the negative proton project. It was called the Bevatron meaning Bev-tron. And it was thought of as a general research tool which had been built to have the capacity, the capability of doing this particular thing. That decided how big it was, so to speak. But nobody spoke of "How much is it going to cost to get the negative proton?" We spoke of "How much is it going to cost to build the bevatron, and then use it for research?" One of the early major programs that was carried out was indeed to get the negative protons, which was done in 1954, something like that. But I like to think of those two things—the Mohole facilities and the Bevatron facilities, as being analogous as to cost.

Now turning to your general question, this is a very legitimate question to ask about Project Mohole, and about the national astronomy observatories, and NCAR; in other words, these large-scale things that, once undertaken, are commitments to follow on and are "big science," if you will. I believe that in the areas of basic research the National Science Foundation definitely has a role, should have a role in doing this sort of thing. It doesn't have such a role, for example, in the biggest accelerators. This is in the AEC, the natural consequence of the fact that the biggest accelerators were an outgrowth of nuclear physics, ordinary nuclear physics, and also the fact that the logical first home for these very big accelerators was in the national laboratories of the AEC. Had history been otherwise, it might well have been logical for the Science Foundation to do that

and maybe sometime they will, I don't know. That is, take some part in it.

We have, of course, as you know, financed an accelerator of about 10 billion volts at Cornell at a cost of about $12 million. But that was because it was a university accelerator as distinguished from the national laboratory type of institutions that build the very biggest accelerators.

There is no question that a great many people think of this as being in competition with what they call little science, in competition with the small project grants that are scattered around among innumerable universities and colleges, but I think these big projects must be done, and I think the National Science Foundation should do its share. Perhaps its share is larger than most.

Mr. DADDARIO. Mr. Davis, do you have any further questions?

Mr. DAVIS. Mr. Chairman, I have just one observation. If the National Science Foundation had not had the authority to go forward with Project Mohole, and if some Member of Congress had introduced a bill which would have authorized NSF to carry out Project Mohole, when that bill was brought before a committee and hearings were held, and then it went before the Rules Committee of the House, and the whole project was discussed and debated on the floor of the House, I can't help but believe that the word "boondoggle" would be the most frequently heard word in the debate. This project involves such an esoteric pursuit that it is difficult for a person to judge its merits. The average Member of Congress is a layman in the scientific sense. I think Mr. Vivian is probably one of the few Members of Congress that does have a real scientific background. The thing I am leading up to is that perhaps it is better that a project such as Mohole is handled in such a way that it doesn't require a complete airing out in public.

If the scientific community agrees that it ought to be done, maybe it is better that it can be done without the necessity of a full public airing, because the general public is so far behind the scientists in deciding where substantial effort ought to be put forth in these strictly scientific endeavors. For that reason, perhaps, you are better off because of the broad charter for NSF since the only committee in the House of Representatives that really has to examine the propriety of your proposed expenditure is the Appropriations Committee.

Would you care to comment on that?

Dr. HAWORTH. I think I would make just this one observation: That is, I think that deciding on what, among the great variety of scientific things could be done, that that is more difficult for Congress than to decide among the variety of, say, social things that could be done.

Of course, also, in a sense, except for the question of the funds, which is involved in both cases, it has less direct impact on the public. Whether we do Project Mohole or some other science project has for less impact on the public than whether you pass one piece of social legislation or another piece of social legislation.

Mr. DAVIS. That is true. We have a hard enough time with that, I might say.

Mr. DADDARIO. Don't you think, following that one up a bit, that if you can properly explain a project and excite the public by it, that

you have also contributed something to the whole field of educational effort which is, in a sense, behind everything we are trying to do?

Dr. HAWORTH. Yes, that is right. As I said earlier in response to some of the questions about authorization legislation, I think, to have Project Mohole and these other things discussed in hearings is a good thing. I am not competent to judge whether it should be an authorization hearing or a hearing in a more general sense.

Mr. DADDARIO. Mr. Conable.

Mr. CONABLE. Doctor, at this stage in the proceedings, I wonder if you have any requests to make of the committee. For instance, do you feel that there has been sufficient dissemination of information about these hearings? What will you expect of us in this line, in order to perhaps improve your general relationship with the scientific and academic community? I would like to leave it just in a general frame. Now that the committee is beginning to deliberate and trying to digest the great mass of information that has come in, are there any areas of concern that you have? I think it would be helpful to us to know what they are.

Dr. HAWORTH. Well, you asked two or three specific questions. Let me answer first the question of whether there has been enough public information about the hearings.

I would divide my answer into two parts. Certainly the scientific and academic public are very much aware of these hearings. There has been a great deal published in periodicals such as Science magazine, for example. As I said, scientists are very much aware of the hearings, and their reactions, initially, have been—as far as I know, and I have seen nothing to the contrary—have been very favorable to the way the hearings have been conducted. The fact that you have had such a very representative set of witnesses, and the searching but the sympathetic way in which you have asked your questions and so on, have been very helpful.

Now, with respect to the general public, I really don't know, but I am not nearly as aware of a general public interest in the hearings. There were, of course, newspaper stories when the hearings started. There have been some, from time to time, about some aspect of other, but certainly, as would be expected, there has been nothing like the interest, among the general public, that there has been among those more immediately affected.

I think that one of the very great virtues of the hearings, which will happen automatically to a considerable extent, is a thing that Mr. Davis referred to in his original questions, namely that clearly the rest of the Members of Congress look to this committee for knowledge and information about the National Science Foundation. And I think the greater the variety of ways in which they become informed and learn more about us and what we are trying to do and what our strengths are and what our weaknesses are—and we certainly have weaknesses—the better it is. You asked me what you can do. I think one of the things that would be most helpful to us is for you to intensify that information process as much as you can, because the more knowledge everybody has about any subject, the better. I believe in people being informed. And I think that the more you can do to make the rest of Congress aware of these things, including the bad side, the better.

It is also true, though it is a more ephemeral thing, with respect to the public, that the more Congress as a whole can do to make the general public aware, not just of the National Science Foundation but of the total picture of science as it affects the country, the better; and—particularly because of your responsibilities and ours—the role that the Federal Government plays in all this, because there is certainly a great lack of understanding among the public about what science really is. Even such magazines as Time and Newsweek and Life and various other magazines, will have on a page labeled "science" something that isn't science, at all. It may be an application of science or it may be a gadget.

I think that you, who represent and visit among all the people of the country, can help a great deal in creating a better understanding of what are the aims, the objectives, the utility and the needs of science.

Mr. CONABLE. Do you feel there are any gaps in the inquiry that should be filled before we retire to deliberate?

Dr. HAWORTH. I am not aware of any.

As a matter of fact, before we answered all these questions, I thought we probably should end up by writing a document that pulls some of these things together. But the hearings have been so complete and the questions so searching that I feel that virtually everything has been said that needs to be said.

Mr. CONABLE. In other words, you are willing to stand on this record?

Dr. HAWORTH. I am willing to stand on this record, yes.

Mr. CONABLE. Thank you.

Dr. HAWORTH. I know that there was some question of whether we could get the questions answered in time, but I really believe, Mr. Chairman that the record is pretty complete, or so it seems from where I sit.

Mr. DADDARIO. I am glad to hear that.

Mr. Vivian.

Mr. VIVIAN. As I am sure you are aware, there have been suggestions that there should be roughly a 15-percent per year increase in the support of the sciences generally, but the National Science Foundation in particular. The argument was based, to a very considerable extent, on the growth in population and the growth of persons trained in science, with the percentage of those trained in science I believe holding fairly constant. Also, in light of the fact that there is about 50 percent of our total population below 25 years old, and the total number of students in college has risen by 50 or 60 percent in only a few years, these are causes for a 15-percent rise.

Looking forward to the possibility that such a 15-percent increase will be approved by the Appropriations Committee, which is only a possibility, I have heard very little information on the subject of exactly where NSF would spend these additional funds.

I would like to know in particular what technical fields you anticipate will receive this 15-percent expansion. Finally, what new international role you would expect to have with this percentage increase, an increase which would double the size of NSF's budget in another 5 years.

Dr. HAWORTH. Well, let me start by clarifying a little the question of the 15 percent.

Actually, this 15 percent was an attempt—in the last budget year and this one, because we don't yet have anything better for this one—to make some kind of a prediction of what the requirements will be.

Now, this applied only to what I call academic science. These demographic arguments which were the basis, of course, were applied to the universities and colleges on the basis of growth of student population. Also, the 15 percent is supposed to be the total, the Federal rise, not necessarily the NSF rise. But NSF, in this case, was a sort of stopgap, or the balance wheel in the 1966 appropriation request.

Mr. VIVIAN. I would like to say if the 15-percent increase were applied across the board to the $15 billion total which the Federal Government has been spending in research and development, the increase would be far greater. If it was only in the research area, it would still be quite large.

Dr. HAWORTH. I was being more restrictive than the research area. I was saying only the research area because the universities don't do development, really. Only the research area and only the research area in the academic institutions. So it is—what is it—about $1.5 billion that goes to the universities, to which the 15 percent would be applied.

Mr. VIVIAN. Yes.

Dr. HAWORTH. And, as I say, this was thought of as the total Federal support of the universities for research, that ought to go up to about this rate, and then it was said that the NSF's support of the universities ought to go up—would, perforce, go up more than 15 percent, because some of the mission-oriented agencies aren't going up that fast.

As I said, this judgment was based essentially on a demographic argument. You are quite right in distinguishing between little science and big science in this respect, because I don't know how one can predict big science. It has its ups and downs. You build a big accelerator, committing a great deal of money in one year, and there may not be nearly as much in the next year or there may be in another year two big things, and so on. And I don't know how to make any statistical prediction about that sort of thing.

Now, with respect to whether the 15 percent is right, or not——

Mr. VIVIAN. Let me suggest that we do not argue whether it is right for the moment. I would like to know, if you get the funds, what do you do with them?

Dr. HAWORTH. Let me say I think it is in the right league, but we must find better ways to determine it.

I don't have any basis for saying that the distribution of support among the various fields and disciplines of academic science, is likely to be in the next few years very different from what it is now. For one thing, the distribution is determined by the interests of the existing faculties at the universities. And these will not change in proportion very rapidly. You aren't going to make biologists out of very many physicists, although occasionally one becomes a biophysicist, and so on.

There are some fields that are coming forward more rapidly than others, ones that perhaps got started later, and some of the interdisciplinary fields. Certainly biochemistry has come along very rapidly in the past few years, compared to other kinds of biology or other kinds of chemistry. But my feeling is that in this realm—and again I am not getting into the research supported for special ends, either in Government laboratories or in industry or development or things of that sort—that it is largely a self-governing mechanism; that as fields become more productive, scientifically, then more interest is created, and more people go into them.

But I don't see any sharp trends.

Mr. VIVIAN. You don't anticipate applying what I will call "Washington enthusiasm" to any given subjects?

Dr. HAWORTH. Well, there is a certain amount of that but in the activities that we have it is not a very dominant factor. As I said earlier, we recognize from time to time that there are areas that aren't being supported well enough. A good example that I don't think I mentioned before was that way back, long before my time, it looked as though the old classical field of systematic biology was going to lose out because of the popularity of other newer fields such as molecular biology and so forth, and the Foundation deliberately started a program of support for systematic biology. It was a modest program but it kept the field from withering.

Another example, where the Foundation decided it ought to put additional emphasis was organic chemistry. Hence proposals in that field were especially encouraged. We have given some special emphasis to the atmospheric sciences, and certainly the Federal Government has done so in oceanography, partly because of the interests of the agencies, partly because of that of Mr. Kennedy and, partly because of Congress interest. And I think these field sciences will probably grow relatively more in expenditures than the more fundamental sciences.

Mr. VIVIAN. Can I ask then about the big science——

Dr. HAWORTH. And the stimulation of interest in Washington undoubtedly is helping that process.

Mr. VIVIAN. In terms of little science, then, you would anticipate that it would be determined largely by the distribution of faculty interests existing at the time?

Dr. HAWORTH. And of course, their successors.

Mr. VIVIAN. Five years from now, what do you anticipate will be the projects that NSF will be supporting in big science?

Dr. HAWORTH. Well, I could answer this better after we get all the reports of the studies that the National Academy is making, but I can give a few examples. I really shouldn't qualify or shouldn't identify all this as big science, but, for example, there is a very definite need for more facilities in the field of astronomy, ground-based astronomy—for more of the larger optical telescopes, for bigger radio telescopes, particularly various kinds of large arrays which seem to be the best way to get very high resolution. There is a need to get some high resolution, both optical and radio telescopes, in the Southern Hemisphere, for example. There is very little down there.

One field that I wouldn't classify as big science, because of its usefulness all across the board, but it is big money, is the computer field. The needs of the universities, for example, for computers——

Mr. VIVIAN. You don't see yourself developing computers, but rather supplying them; is that right?

Dr. HAWORTH. Yes. I think there should be a very few computer development centers in the universities, but that is not really the thing to which I am speaking.

I think that there is going to be a terrific growth in the need for computers for the support of the sort of science that they are already supporting, for greater use in the social sciences, for use in education, and so on.

I think that the universities are also a place to develop software, as compared to the computers themselves. This means the ancillary things that go with the computer.

Mr. CONABLE. Will the gentleman yield a minute on that point?

Mr. VIVIAN. Yes.

Mr. CONABLE. I was under the impression that the computer industry was very competitive and that it was constantly seeking new ways of processing data. Yet, it appears that this is something that requires Federal support.

Dr. HAWORTH. Well, I am speaking about a particular facet of computers.

The ways in which, for particular fields of science or for the particular needs of universities, you make use of the central core computer.

I am not speaking of computer development—although, as I said, I think there should be a very few centers of computer technology, proper, just as there should be in any field, because after all, industry has to draw its people from the universities. If for no other reason, there should be a very few centers where the basic technology of the computers themselves is worked on.

But I think that, more importantly there is need for greatly increased support of some of the other aspects. There needs to be, for example, a great deal of thought and some trials in connection with this question: if there is need for processing a great deal of data in a given university or even in a larger area, is it better to have a very large computer and then have satellite stations that feed into that computer, or is it better to have several smaller computers scattered around?

Now, that is not a big science in the same sense that Mohole is big science, but as I have said, it is big money.

Mr. VIVIAN. Big money in the universities?

Dr. HAWORTH. But it is in the service of both little and big science.

Mr. VIVIAN. Are there any specific projects in big science in which you expect to be involved?

Dr. HAWORTH. Well, there are some. Certainly, in the example I gave of astronomy. If we are going really to keep pushing in astronomy, there must be some very major facilities. Now, I am not saying that they will be built, or that if they are we will build them, but this is a natural field for the National Science Foundation.

Another example, of course, is space-based astronomy, where NASA of course, has the responsibility for the platforms and things of that

sort, but where I think other agencies should ride piggyback with their equipment to take advantage of the platforms.

Departing now from the Science Foundation, there is certainly a need for much larger particle accelerators if we are going to really solve the problems of elementary particle physics.

Mr. VIVIAN. This would be under AEC, in your view?

Dr. HAWORTH. Yes.

Mr. VIVIAN. I am trying to stay strictly within NSF. What do you see there.

Dr. HAWORTH. I don't think I can put my finger on any.

Mr. VIVIAN. May I switch, then, to the international role, Doctor? Do you foresee activity there?

Dr. HAWORTH. This is something that we have been discussing in the Foundation a great deal, but we haven't come to any definite conclusions.

There are really four areas of international science. There is the area of cooperation like the IGY, or the IQSY, or the Indian Ocean Expedition, or the Antarctic program, where there is a concerted activity in which planning is done internationally, but where each country carries out its own program. This cooperation, of course, is in the interest of science, although we put great stress on the fact that it also helps international relations.

A second area is where for one reason or another a Federal agency might support science in another country because—let's say in advanced countries, like those in Western Europe—because for some reason something we would like to see done can be done better there, than here; either they have a group of people that are unusually well qualified, or there is a geographic aspect to the scientific activity, or something of that sort. I don't foresee any great increase in that kind of thing.

A third area is at the other extreme. It is the support of science and science education in the developing countries, where obviously the principal objective is not to get something that is immediately useful in the scientific sense, but where the objective is to help the country develop; in other words, where it is really a foreign policy objective. The Science Foundation clearly does not, with its present charter, have authority to support that sort of thing, because our support is supposed to be for the benefit of American science. We do, however——

Mr. VIVIAN. You do subcontract to AID, however.

Dr. HAWORTH. We do, yes; that is what I was coming to. We do, however, have a certain amount of activity carried out on behalf of AID with AID funds; our activities in Central and South America are of that kind. I would like to see more of that. I think that the Science Foundation has certain capabilities, because of its relationship with the scientific community and so forth, that can be put to very good use.

Then, finally, the fourth area is what is customarily referred to as the "gray area," which lies in between, where the science is good but not necessarily any better than, or quite as good as, the science you could support in this country, but where foreign policy objectives are involved. This is the activity that we don't quite know whether we

ought to undertake or not. Should we, other things being equal, support some science in some place where our foreign policy objectives would be helped, even though we could get it done just as well at home. In other words, should we apply to this the same criteria that we now apply with respect to geographic distribution within the United States, where if we can get it done equally well in more than one place, we take geographic distribution into account. I just don't know whether we should get heavily into that sort of thing or not. And I think this doesn't apply just to the Science Foundation; I think this is a question that would be fruitful for Congress to think about—how the objectives of science and the objectives of foreign policy can be combined effectively and appropriately.

Mr. VIVIAN. The final part of this question is that presently scientific activities require about 15 percent of the Federal budget. Earlier this morning I spent some time at Goddard Space Flight Center. There is a concentration of dollars per cubic inch out there which is rather enormous. Do you have any view of what percentage you think will be spent in these areas 10 to 20 years from now?

Dr. HAWORTH. No.

Mr. VIVIAN. I don't myself. I am curious.

Dr. HAWORTH. I certainly don't know. However, most of the rest of members of this subcommittee heard me say about 2 years ago that we must think of this in two distinct facets. One is that most of this $15 billion just happens to be science, and the applications of science. It is really the pursuit of national goals. Defense is a prime example. I am now speaking of development and applied research that verges on development, where things are done not in a basic sense but because we need a weapon or a piece of equipment. I don't really think one should refer to a $15 billion package for research, any more than one should think of an x billion dollar expenditure for law or for the practice of economics. Most of the $15 billion package is a means to an end, not a scientific end but a national goal, such as the country's defense.

On the other hand, underlying these means to achieve national goals is the generality of science, both basic and applied research and science education. I think that for these—it is reasonable to think of a total package, and I think it will grow. Clearly it can't grow relatively faster than the gross national product indefinitely, any more than anything else can, because we can't have science constitute half the gross national product or something like that. But I think it will grow.

The big expenditures for development, I suppose, will come and go as goals change, as needs change. If Mr. Foster and Mr. Tsarapkin are successful in disarmament negotiations in Geneva in x years, why this could change the picture tremendously, of course.

So I just don't see any way to predict that sort of thing.

Mr. VIVIAN. Do you feel that the present 15-percent figure is likely to decrease significantly?

Dr. HAWORTH. I don't foresee that, unless something drastic happens.

Mr. VIVIAN. Thank you, very much.

Mr. DADDARIO. Dr. Haworth, many of these questions lead to an increasing role for the National Science Foundation.

In your answers, you refer to the fact that you can only fund a certain number of the projects which are proposed to you. Your project support budget for basic research for the fiscal year 1966 is estimated at $155 million, and you say the estimated amount to require reasonable support for all good proposals would be closer to $280 million. You add to that an unknown figure, since many people do not submit proposals who probably could have submitted proposals. Then as the mission-oriented agencies become restricted by funding, they look to NSF to do more. This gets us to the point where you, as Director, have a great responsibility to handle this as it develops.

Reorganization Plan No. 5 gives you, as the Director, the authority to delegate appropriate authorization of performance to any other officer. What are your plans in this regard? What do you have in mind, if you have reached the point where you could give us some of your thoughts?

Dr. HAWORTH. Well, I haven't got it all completely crystallized, but there are two or three facets to it. One reason for the reorganization plan was to get clearly stated something that we all knew was the intent of Congress, or thought we knew, with respect to my authority to delegate things, for example, to the Deputy Director. The Deputy Director is provided for in the statute.

During the last several years of his directorship, Dr. Waterman didn't have a Deputy Director. There was a very heavy load on him—he signed all the grants, for example.

I have had Dr. Wilson do a major portion of that. I say we share it, but he carries the horse and I carry the rabbit with respect to that activity.

And incidentally, this is authority delegated to me by the Board. There didn't seem to be any problem about my delegating down the line things that are vested in me by the act.

Mr. DADDARIO. You said in your answers to the questions, "including functions delegated to him by the National Science Foundation."

Dr. HAWORTH. Yes. There are a great many grants, for example, that are rather picayune in terms of dollars. I don't mean they are unimportant.

For example, we give a great many travel grants and there are other grants that are just a few thousand dollars, and so on. I plan, although I haven't worked it all out, to delegate some of that sort of thing to the Associate Director level. And there are various day-to-day things of other sorts that I would like to delegate to that level, and they, in turn, then, will be able to delegate some of the things that they do down to the division directors. It is not any very major—it is not going to be an upheaval in the Foundation or anything of that sort. But it just makes it possible to operate in a way, or let's say we no longer are forced to operate in a way that was quite appropriate when the Foundation was small, but not now when it is in the half-billion dollar league—and I am very much opposed to signing a piece of paper that is laid in front of me without studying and understanding it. The fellow that made the decision is the fellow that lays it in front of me, and there is no point in my trying to pretend that I made the decision, and therefore am approving something if I really took no part. I won't do it, as a matter of fact. I always

read everything I sign. And this gets to be impossible for Dr. Wilson and me to do, as the Foundation grows.

I was smiling, when you started your question Mr. Chairman, because you said, "These questions lead to" and I thought you were going to say "a lot more questions."

Mr. DADDARIO. Well, I must admit, Dr. Haworth, that every time you come before us you have, in fact, pointed the way to other questions. This is not an exception, but it can't go on forever. We are at the end of the formal part of our hearings. I must ask you to bear with us as we prepare a few more questions for you. I assure you that they will be very few.[1]

I know we are going to have some activity on the floor, so we will not continue any further. I do want to give you time for your concluding statement. You have already, as I recall it, eliminated 1 minute 15 seconds from your 5 minutes, and then I may have a couple of things to say.

Dr. HAWORTH. Okay.

I think you can guess what I am going to say, and I will repeat some things that I said earlier, just to give a more complete picture.

I want to conclude by saying what I think about the worthwhileness of these hearings. I think they have been of very great value. As I said earlier, they have made us think. I hope they have been informative to you. They have made us think ahead of our daily problems, which we tend to get immersed in all the time.

They have helped, I hope, to give you a broader picture and understanding of the Foundation, of its objectives, of its programs and of its problems, and, in turn, as you said, to other Members of Congress and to the public at large. You have certainly marshaled a wide spectrum of witnesses who have been able to speak of the Foundation from a great many different angles and points of view and differing experiences, and so on, which I think has been a very good thing.

Your questions have been very searching, but always very sympathetic, and we deeply appreciate that.

You, Mr. Chairman, and all the members of your committee have shown very great courtesy and understanding in overlooking—and I am speaking personally, now—my own shortcomings and inadequacies in appearing before you, and I am very deeply appreciative of it, and thank you, very much.

Mr. DADDARIO. Dr. Haworth, the constant attendance by the members of this committee, and the attention they have paid to this whole review indicates the interest that the Congress, and the country, too, has in the National Science Foundation.

I first want to compliment and thank all the members of this committee for their attention to these hearings over a long period of time. I would also like to thank Mr. Yeager, Dr. Wenk, and all the other members of the staff who have helped us prepare for the testimony as we have gone from day to day.

Finally, I would like to add a very large note of thanks to you, Dr. Haworth, and to the members of your staff, and all of the other witnesses who have been here and who have added so much to these hearings.

[1] The questions referred to, and the witness' response thereto, will be contained in vol. II of these hearings.

We are a long way from the time when we will have analyzed the testimony and come to some objective conclusions and recommendations. This will probably take us until the end of this year, and perhaps into the beginning of next. However, I do think that we have—you, on your part, and we, on ours—gotten together to the point where we have a better understanding. I would hope we might be successful in making an impression as a committee on the other Members of Congress so we can, by gaining their confidence, make recommendations that will be in the best interest of the country and the National Science Foundation.

These hearings have been interesting, exciting, and educational.

You have done your job well in giving us the opportunity to see some of the problem areas which arise, and I want to thank you and the whole staff of the National Science Foundation for their diligence and the hard work they have put into these hearings.

In a sense, as far as the congressional and legislative responsibilities are concerned, the rest is up to us.

Thank you, and, of course, we will be in touch with you.

Dr. HAWORTH. Thank you, Mr. Chairman.

Mr. DADDARIO. The committee will adjourn to the call of the Chair.

(Whereupon, at 12:23 p.m., the subcommittee was adjourned subject to the call of the Chair.)

BIOGRAPHIES

DR. SANFORD SOVERHILL ATWOOD

Home address: 1463 Clifton Road NE., Atlanta, Ga.
Born: December 3, 1912, Janesville, Wis.
Parents: Charles Starr Atwood and Cora Soverhill Atwood.
Wife: N. Elizabeth Long (August 15, 1936); children: Charles Starr, Elizabeth Ann, Phoebe Ellen, Richard Jay.
Education: A.B., A.M., University of Wisconsin, 1934; Ph. D., University of Wisconsin, 1937.
Chronological list of positions:
U.S. Regional Pasture Research Laboratory, State College, Pa., 1937–44;
Associate professor, Department of Plant Breeding, Cornell University, Ithaca, N.Y., 1944–45;
Associate professor, ibid., 1945–48;
Professor, ibid, 1948–63;
Head of department, ibid., 1949–53;
Dean of Graduate School, Cornell University, 1953–55;
Provost, ibid., 1955–63; and
President, Emory University, Atlanta, Ga., 1963– .
Fraternities: Phi Eta Sigma, Phi Kappa Phi, Phi Beta Kappa, Sigma Xi, Phi Sigma, Gamma Alpha, Social fraternity, Alpha Chi Rho.
Learned societies: AAAS; AAUP; Genetics Society of America; American Society of Agronomy; Association of Southeast Biologists.
Membership in—
Board of directors, Salzburg Seminar;
Board of directors, Alpha Chi Rho Educational Foundation;
Vice chairman, Council of Presidents, University Center in Georgia (1964–65);
Board of directors, Atlanta Chamber of Commerce;
Commission on Plans and Objectives, America Council on Education (1963–66);
Board of Visitors, Freedoms Foundation at Valley Forge;
The Atlantic Council of the United States;
Technical Advisory Committee of the Atlanta-Fulton County Economic Opportunity Authority (term to run until June 30, 1966);
Committee on Economic Development; and
Rapid Transit Study Commission.
Listed in Who's Who, American Men of Science, Presidents and Deans of American Colleges and Universities.

DR. THOMAS F. BATES

Present position: Science adviser, Department of the Interior. Duties include the furnishing of advice and consultation on programs and management of the Department's research and development program, coordination and representation of research and development externally and the general review and evaluation of research to accomplish the Department's mission in natural resources conservation and development. Serves as a member of the Federal Council for Science and Technology and the Interdepartmental Committee on Atmospheric Sciences. Heads U.S. activities of the United States-Japan Cooperation on Natural Resources under the Committee on Trade and Economic Affairs, effective June 1, 1965.
Born: January 2, 1917, Evanston, Ill.
Degrees: B.A., Denison University, 1939; M.S. Columbia University (geology), 1940; Ph. D. Columbia University (geology), 1944.

Positions at the Pennsylvania State University:
College of Mineral Industries:
Instructor, department of mineralogy, 1942–45;
Assistant professor, department of mineralogy, 1945–49;
Associate professor, department of mineralogy, 1949–53;
Director, mineral constitution laboratories, 1950–57; and
Professor of mineralogy, 1943 to present.
University administration:
Assistant to the vice president for research, 1961 to present;
Director, Institute for Science and Engineering, 1963 to present;
Assistant dean for programs, graduate school, October 1964 to present.

Other organizations served in a consulting capacity (former): C. K. Williams & Co., New York and Pennsylvania company, Sun Oil Co., Carter Oil Co., Shell Oil Co., Georgia Kaolin Co., Kerr-McGee Oil Industries, Pacific Uranium Co., International Minerals & Chemical Corp.

Memberships: Fellow, Geological Society of America; fellow, American Mineralogical Society; American Crystallographic Association; Electron Microscope Society of America; Mineralogical Society of London; American Association for the Advancement of Science.

Fields of research:
X-ray and electron microscope studies of clays and other minerals;
Electron microscope studies of glass and various geological materials;
Mineralogical investigations of fine-grained rocks;
Mineralogy, petrology, and chemistry of uranium-bearing shales and lignites in Tennessee, South and North Dakota, California, and Florida;
Studies of rock weathering and clay formation in Hawaii, California, Pennsylvania, North Carolina, and Georgia.

Résumé of duties at the Pennsylvania State University:
As professor of mineralogy: Teaching of one graduate course;
Principal investigator of two NSF-sponsored research programs;
Supervisor, three Ph. D. candidates;
As assistant to the vice president for research: Concerned primarily with grants and facilities program of the university, dispersal of research funds, development and support of all-university research programs.
As director of the Institute for Science and Engineering: In charge of eight interdisciplinary research units as follows: Center for Air Environment Studies, Computation Center, Institute for Research on Human Resources, Institute for Research on Land and Water Resources, Laboratory for Research on Animal Behavior, Laboratory for Human Performance Research, Materials Research Laboratory, and Ordnance Research Laboratory.
As assistant dean for programs of the graduate school: Concerned with the development and administration of graduate academic programs of an interdisciplinary nature (e.g., solid state technology, acoustics), and with all activities such as fellowship programs, facilities, etc., that require liaison between the research and graduate school offices.

DR. NYLE C. BRADY

Dr. Nyle C. Brady is Director of Science and Education in the U.S. Department of Agriculture. He serves as the Secretary's chief science officer and coordinates the research and education activities of the Department. As a member of the Federal Council for Science and Technology, he participates in the coordination and planning of Government-wide research.

Dr. Brady attended elementary and secondary schools in Manassa, Colo. He holds a B.S. degree from Brigham Young University, Provo, Utah, and a Ph. D. in agronomy from North Carolina State College, Raleigh, N.C.

Following receipt of his Ph. D. in 1947, he became an assistant professor of soil science at Cornell University, Ithaca, N.Y. In 1950 he was promoted to associate professor; 1952—Professor; 1955–63 served as head of the department of agronomy; 1959 (on 7 months leave) served as assistant to the Director of Agricultural Relations, Tennessee Valley Authority.

Dr. Brady has been on five missions to the Philippines—the most recent involving a cooperative education project financed by the Ford and Rockefeller Foundations. He has also visited Taiwan, Vietnam, Honduras, the Soviet Union, and Rumania.

He was president of the Soil Science Society of America in 1964, is a member of the American Society of Agronomy, the American Association for Advancement of Science, American Institute of Biological Science, Rotary International and Sigma Xi. At the Eighth International Soil Science Congress in Bucharest he was appointed Vice President of Commission IV of the International Society of Soil Scientists.

Dr. Brady served about 4 years as editor in chief of The Proceedings which is the official publication of the Soil Science Society of America.

He is coauthor of perhaps the most widely used textbook on soil science, "The Nature and Properties of Soils."

His major research interests are in plant nutrition especially as related to root zone temperatures.

He was born in Manassa, Colo., October 25, 1920, married the former Martha Cornum of Sanford, Colo., and they have two sons and two daughters.

Dr. Brady served in the U.S. Army 1945–46.

DR. HARVEY BROOKS

A native of Cleveland, Ohio, Brooks received his bachelor's degree in mathematics from Yale in 1937. After a year as a Henry fellow studying mathematical physics at Cambridge University, he came to Harvard, where he received his Ph. D. in physics in 1940. In 1940 he was elected for a 3-year term as junior fellow in Harvard's Society of Fellows, but took leave of absence from this appointment after about a year to enter warwork, and never completed his term.

During World War II Brooks served as a staff member of the Harvard Underwater Sound Laboratory directed by Prof. F. V. Hunt. Here he was concerned first with the development of basic techniques for what later became known as scanning sonar and later with the design and construction of a prototype of the first U.S. acoustic homing torpedo, an antisubmarine weapon which saw service in the latter part of World War II. In 1945 Brooks moved with the torpedo project to help set it up at the Ordnance Research Laboratory at Pennsylvania State College. He served for a year as Assistant Director of this Laboratory under Dr. Eric A. Walker.

In 1946 Brooks moved to Schenectady to join the research laboratory of the General Electric Co., where he organized a small theoretical physics group which later became the nucleus of the Knolls Atomic Power Laboratory. Shortly after the establishment of this laboratory Brooks became its associate head under Dr. K. H. Kingdon. The Knolls Atomic Power Laboratory worked on the development of technology for sodium cooled intermediate energy spectrum power reactors. The experience which Brooks gained in Schenectady resulted in a continuing interest in reactor technology, even after his move to Harvard as Gordon McKay professor of applied physics in 1950 resulted in a shift of interest to solid state physics.

Since 1950 Brooks' major research interest has been in solid state theory. In collaboration with others he has worked on the interpretation of the behavior of semiconductors at high pressures. He has published papers in the field of radiation effects on solids, and on various aspects of the quantum theory of solids, as well as on some aspects of nuclear reactor theory. In 1960 he was one of the first five recipients of the Ernest Orlando Lawrence Award of the Atomic Energy Commission in recognition of his work on the theory of fast reactors and in the field of reactor safety. Recently he has become concerned with the relations between science and public policy and has published several papers in this area.

Brooks has served as consultant to numerous industrial organizations and on many Government committees. His Government service includes the Undersea Warfare Committee of the National Research Council, the Advisory Committee on Reactor Safeguards of the Atomic Energy Commission, the Naval Research Advisory Committee, the President's Science Advisory Committee, and the National Science Board.

In 1956 Brooks founded the international journal Physics and Chemistry of Solids, and has remained its editor in chief ever since. In 1961 he was elected to the American Philosophical Society and in 1962 to the National Academy of Sciences. He has been a fellow of the American Academy of Arts and Sciences since 1950. In 1965 he became Chairman of the Committee on Science and Public Policy of the National Academy of Sciences and also Chairman of the Engineering Section of the National Academy.

He is a trustee of the Woods Hole Oceanographic Institution, Smith College, Case Institute of Technology, and is a director of Raytheon Co. He holds honorary D. Sc. degrees from Union College (1962), Yale University (1962), Kenyon College (1963), Harvard University (1963), and Brown University (1964).

Brooks is married and has four children; he and his family live in Cambridge.

DR. BRYCE CRAWFORD, JR.

Bryce Crawford, Jr., was born in New Orleans, La., and grew up mostly in the San Francisco Bay region and in southwestern Texas. His college and university years were spent at Stanford, where he received the A.B. in 1934; the A.M. in 1935; and the Ph. D. in chemistry in 1937. He then spent 2 years at Harvard University as a national research fellow working in the laboratories of Prof. Bright Wilson, Jr.; following this he spent a year at Yale University as instructor in chemistry. Then in 1940 he moved to the chemistry department at the University of Minnesota, which has been his home base ever since; he is now professor of physical chemistry at Minnesota and dean of the graduate school here.

During the war years he was engaged in research on rocket propellants under the OSRD program, carrying out research both in his own laboratories at Minnesota and in the Allegany Ballistics Laboratory at Cumberland, Md. In the main his interests have always centered on molecular spectroscopy and molecular structure.

In 1950–51 he spent some time at the California Institute of Technology and at Oxford University, as a Guggenheim fellow and as a Fulbright fellow at Oxford. He is chairman of the chemistry section of the National Academy of Sciences, and a member of the American Chemical Society, the American Physical Society, the Optical Society of America, the Coblentz Society, and the National Academy of Sciences. He has also served as chairman of the Council of Graduate Schools in the United States.

DR. BOWEN C. DEES

Born: Batesville, Miss., July 20, 1917.
Marital status: Married, one child.
Education: A.B., Mississippi College, 1937; Ph. D., New York University, 1942.
Experience:
- Academic:
  - Graduate assistance, New York University, 1937–42;
  - Instructor (physics), New York University, 1942–43;
  - Professor (physics), Mississippi College, 1943–44;
  - Massachusetts Institute of Technology Radar School staff member, 1944–45;
  - Assistant professor of physics, Rensselaer Polytechnic Institute, 1945–47.
- Federal Government:
  - Physicist, Scientific and Technical Division, General Headquarters, Supreme Commander for the Allied Powers, Tokyo, 1947–50;
  - Division Chief, Scientific and Technical Division, General Headquarters, Supreme Commander for the Allied Powers, Tokyo, 1950-51;
  - Program director for fellowships, National Science Foundation, 1951–56;
  - Deputy Assistant Director for Scientific Personnel and Education, National Science Foundation, 1956–59;
  - Assistant Director for Scientific Personnel and Education, National Science Foundation, 1959–63;
  - Associate Director (Scientific Personnel and Education), National Science Foundation, 1963;
  - Associate Director (Planning), National Science Foundation, 1964—.

Organization membership: American Association for the Advancement of Science, American Association of Physics Teachers, American Physical Society, American Society for Engineering Education, American Society for Public Administration, and Society of Sigma Xi.

WILLIAM A. DOUGLASS

William A. Douglass is president of Careers, Inc., a firm which he founded in 1951 while a senior at Yale.

It was during his junior year that, as vice chairman of the Yale Daily News, he teamed with other student officers of that newspaper to put together a job guide about American industry. Their own difficulty in tracking down accurate and complete job information provided the impetus for the project. Each business firm provided a full-page story of their opportunities for college seniors in the current year. The result was published in the form of a book titled "Career: for the College Man," and was distributed without cost to 22,000 seniors in northeastern colleges. The employers underwrote all costs.

Except for a brief stint with the Central Intelligence Agency in Washington after graduation, Mr. Douglass has been with Careers, Inc. ever since. Until 1954, he represented the company in the Midwest, moving to New York upon his appointment to the presidency.

Under Mr. Douglass, Careers has developed a broad capability in recruiting services. The original college publishing program went national in coverage in 1952 and added special editions for the military reservists in 1958. More than 2 million copies of successive annual editions have now been circulated. A second area of concentration has been the recruitment of engineers and scientists. Careers' continuing programs in this area have made it by far the largest professional recruitment service in America.

The matching of men and jobs calls for very sophisticated communications systems. In 1958 Careers set up a register for its engineering and scientific candidates modeled along the lines of work accomplished at the National Science Foundation. In 1960 the company inaugurated a new concept in job interviewing, organizing groups of companies into a nationwide tour offering engineers and scientists interview sessions in major metropolitan areas. An instantaneous success, these sessions called career centers, have continued on as often as a once-a-week basis ever since.

The accumulation of résumé data on thousands of people who are either seeking their first job or who are seeking a change of job provides Careers with a wealth of research material for the better understanding of the manpower market. In addition to his own company's research releases, Mr. Douglass has written numerous articles, particularly in the technical manpower field, and has been a guest lecturer at George Washington University and New York University. He has also consulted from time to time on manpower problems at the behest of various Federal agencies and congressional committees.

Mr. Douglass was born on May 30, 1929, in Lake Forest, Ill. He is the third and last son of Kingman Douglass, at that time a Chicago broker, now with Dillon Read & Co., in New York City, and Helen James Douglass. Before Yale, he attended prep school at St. Mark's School, Southborough, Mass.

DR. HUGH LATIMER DRYDEN

Dr. Hugh Latimer Dryden has been Deputy Administrator of the National Aeronautics and Space Administration (NASA) since its creation by the Congress in October 1958. He is internationally recognized for his scientific contributions to fluid mechanics and boundary layer phenomena, and has been highly honored for his leadership of research and development associated with aeronautics and astronautics. He became Director of Research of the National Advisory Committee for Aeronautics (NACA) in September 1947, and was named Director of NACA in May 1949, serving until it was superseded by NASA in 1958.

Dr. Dryden currently holds a number of posts in addition to his responsibilities for the U.S. civilian space program under NASA. He is a member of several scientific committees advising Government agencies, including the Department of Defense and the military services. He is technical adviser to the representative of the United States to the United Nations Committee on the Peaceful Uses of Outer Space. Dr. Dryden is a consultant to the Science Advisory Committee to the President and a member of the Standing Committee of the Federal Council on Science and Technology. He is also a national delegate to the NATO Advisory Group for Aeronautical Research and Development.

Born in Pocomoke City, Md., in 1898, Dr. Dryden earned a bachelor of arts degree in 1916 and a Ph. D. in 1919, both from Johns Hopkins University in Baltimore, Md. He joined the staff of the National Bureau of Standards in 1918, where he performed his distinguished research contributing to supersonic flight of aircraft and missiles. He became Associate Director of the National Bureau of Standards in 1946, having previously served for a short time as Assistant Director. Throughout World War II, Dr. Dryden served on numerous technical groups and task forces concerned with aeronautics and guided missiles for the Joint Chiefs of Staff, the military services, and NACA. In 1945 he was the Deputy Scientific Director of the AAF Scientific Advisory Board appointed by Gen. H. H. Arnold to prepare a report to guide future Air Force research and development.

Dr. Dryden is home secretary of the National Academy of Sciences; charter member, honorary fellow, and former president of the Institute of Aerospace Sciences; honorary fellow of the Royal Aeronautical Society, the British Interplanetary Society, and the Canadian Aeronautics and Space Institute; fellow of the American Academy of Arts and Sciences; foreign associate members of l'Academie des Sciences de l'Institut de France; honorary member, Hermann Oberth-Gesellschaft; founding member, National Academy of Engineering, National Academy of Sciences; honorary member, the American Society of Mechanical Engineers; and a member of numerous other professional societies and organizations. He is a trustee of the National Geographic Society.

Many honors and awards have come to Dr. Dryden, including the following:

First American to deliver the Wright Brothers annual lecture before the Institute of the Aeronautical Sciences (1938).

Sylvanus Albert Reed Award (1940).

U.S. Army Air Forces' Medal of Freedom (1946), the second highest U.S. award.

Presidential Certificate of Merit (1948).

Order of the British Empire (civilian division) (1948).

Thirty-seventh Wilbur Wright memorial lecture before the Royal Aeronautical Society (1949).

Daniel Guggenheim Medal (1950).

Wright Brothers Memorial Trophy (1955).

Ludwig Prandtl memorial lecture of the Wissenschaftliche Gesellschaft für Luftfahrt (1958).

Career Service Award of the National Civil Service League (1958).

Baltimore City College Hall of Fame (1958).

President's Award for Distinguished Federal Civilian Service (1960).

Elliott Cresson Medal of the Franklin Institute (1961).

Langley Gold Medal of the Smithsonian Institution (1962).

First Th. von Karman lecture before the American Rocket Society (1962).

Rockefeller Public Service Award (1962).

John Fritz Medal (1963).

Gold Medal of the International Benjamin Franklin Society (1963).

First Annual Award Dr. Th. von Karman Memorial Citation (1963).

Dr. Robert A. Goddard Memorial Trophy (1964).

Hill Space Transportation Award (1964).

Honorary degrees:

Polytechnic Institute of Brooklyn (Sc. D., 1949).

New York University (D. Eng., 1950).

Rensselaer Polytechnic Institute (D. Eng., 1951).

University of Pennsylvania (Sc. D., 1951).

Western Maryland College (Sc. D., 1951).

Johns Hopkins University (LL. D., 1953).

University of Maryland (D. Eng., 1955).

Adelphi College (LL. D., 1959).

South Dakota School of Mines and Technology (D. Eng., 1961).

Case Institute of Technology (Sc. D., 1961).

American University (L.H.D., 1962).

Northwestern University (Sc. D., 1963).

Politecnico de Milan (M.E., 1964).

Swiss Federal Institute of Technology (Sc. D., 1964).

Dr. Dryden is married and has three children: a son, Hugh Latimer Dryden, Jr., in Chicago, and two daughters, Mrs. Andrew Van Tuyl in Silver Spring, Md., and Nancy Travers Dryden, Washington, D.C. He and his wife, Libbie, live at 5606 Overlea Road NW., Washington, D.C.

DR. JOHN W. GARDNER

John W. Gardner, president of Carnegie Corp. of New York and of the Carnegie Foundation for the Advancement of Teaching, was born in Los Angeles, Calif., in 1912. He is an honorary fellow of Stanford University where he received his A.B. and M.A. degrees. He received his Ph. D. degree at the University of California and holds many honorary degrees from colleges and universities in the United States and Canada.

Before World War II, Mr. Gardner taught psychology at Connecticut College for Women and Mount Holyoke College.

In 1942, Mr. Gardner joined the Foreign Broadcast Intelligence Service of the Federal Communications Commission where he served as chief of the Latin American Section.

The following year he joined the U.S. Marine Corps and was assigned to the Office of Strategic Services. He served with the OSS in Washington, D.C., Italy, and Austria. At the time of his release from active duty, he held the rank of captain.

Mr. Gardner came to Carnegie Corp. in 1946 as executive associate. He became president in 1955, and the same year was made president of the Carnegie Foundation for the Advancement of Teaching.

He has at various times served as consultant to the U.S. delegation to the United Nations, the Air Force, the Department of Defense, the Agency for International Development, the U.S. Office of Education, and to the White House. He served on the Special Task Force on Education which President Kennedy brought together shortly after his election. He was chairman of the U.S. Advisory Commission on International Educational and Cultural Affairs (1962–64), President Johnson's Task Force on Education (1964), and of the White House Conference on Education (1965). He is a member of the General Advisory Committee on Foreign Aid.

He is a recipient of the U.S. Air Force Exceptional Service Award, and in 1964 was awarded the Presidential Medal of Freedom, the highest civil honor in the United States.

Mr. Gardner is a member of the board of the Metropolitan Museum of Art and the American Association for the Advancement of Science; a director of the Shell Oil Co. and the New York Telephone Co.; and a fellow of the American Psychological Association and of the American Academy of Arts and Sciences. He is a member of the Council on Foreign Relations and the Society of Sigma Xi.

As chairman of the Panel on Education of the Rockefeller Brothers special studies project, he was chief draftsman of the report, "The Pursuit of Excellence." He is the author of the chapter "National Goals in Education" in the report of President Eisenhower's Commission on National Goals ("Goals for Americans") and also wrote the chapter "Can We Count on More Dedicated People?" in the book "The National Purpose." He is the editor of President John F. Kennedy's book "To Turn the Tide." He is the author of the books "Excellence: Can We Be Equal and Excellent Too?" and "Self-Renewal: The Individual and the Innovative Society."

DR. ARNOLD B. GROBMAN

Dr. Arnold Grobman is a native of Newark, N.J., and has had an interest in the biological sciences since childhood. He did his undergraduate work at the University of Michigan and graduate work at the Universities of Michigan and Rochester. He received his Ph. D in zoology in 1943 from the University of Rochester and the following year was an instructor in zoology there. During World War II he worked in mammalian genetics in the Manhattan District at the University of Rochester Medical School. In 1946 he joined the staff of the Department of Biology of the University of Florida as assistant professor and, in 1951, became director of the Florida State Museum, a unit of the university. During this period he spent some time at the Oak Ridge National Laboratory as a research associate and also participated in an extensive study of medical education at the University of Florida.

He has been active in a number of professional organizations and is a member of about 30 professional and honorary societies. He has served as president of the Southeastern Museums Conference, vice president and secretary of the American Society of Ichthyologists and Herpetologists and was the 1964 president of that society. He is president-elect of the National Association of Biology Teachers. He was a founder and chairman of the board of directors of the

Florida Foundation for Future Scientists. He has been a member of the National Research Council, Division of Biology and Agriculture, and the executive committee of the American Institute of Biological Sciences. He is currently serving on the council of the American Association for the Advancement of Science and on the council of the Academy of Zoology (India). He has served as chairman of the committee on training of the American Association of Museums. He is a member of the Commission on Undergraduate Education in the Biological Sciences.

His technical publications are primarily devoted to the geographic distribution and systematics of amphibians and reptiles. He has also written papers concerned with educational aspects of museums, secondary schools, liberal arts colleges, and medical schools and, for a number of years, has contributed frequent reviews to the *Quarterly Review of Biology*.

In January of 1959 he became director of the biological sciences curriculum study, with headquarters at the University of Colorado, which was organized by the American Institute of Biological Sciences to work for the improvement of biological education. During its 6 years of existence the BSCS has prepared new curricular materials for use at the secondary school level. The books and films produced by this study are now in extensive use in American high schools. As part of the curriculum study program, he has traveled widely overseas contributing to changes in biological education in India, Thailand, Japan, Taiwan, the Philippines, England, and the several countries in Central America.

Dr. Grobman will join Rutgers University as dean of the College of Arts and Sciences on September 1, 1965.

DR. LELAND JOHN HAWORTH

Leland John Haworth became Director of the National Science Foundation on July 1, 1963, following Senate approval on May 9, 1963, of his nomination by President Kennedy. Dr. Haworth came to the Foundation from the Atomic Energy Commission where he had served as Commissioner since April 1961. He succeeded Alan T. Waterman, NSF's Director since its establishment in 1950.

Dr. Haworth began his career as a high school teacher in Indianapolis, Ind., in 1926–28 and then served as an instructor in physics at the University of Wisconsin, 1930–37. He was a Lalor fellow in physical chemistry at the Massachusetts Institute of Technology, 1937–38. At the University of Illinois, he was an associate, assistant professor, and professor of physics, 1938–47. From 1941–46, Dr. Haworth was on leave from Illinois working on defense projects at the MIT Radiation Laboratory. He was appointed Assistant Director of Brookhaven National Laboratory in 1947 and Director of the Laboratory in 1948. In 1951, he was named vice president and in 1960 president of Associated Universities, Inc., while continuing as Laboratory Director. From 1959–61, Dr. Haworth was a member of the Board of Directors of the Oak Ridge Institute for Nuclear Studies. He became a member of the Atomic Energy Commission on April 17, 1961.

Dr. Haworth was born in Flint, Mich., on July 11, 1904. He received an A.B. in 1925 and an A.M. in 1926, both from the University of Indiana. He was awarded his doctorate in physics from the University of Wisconsin in 1931. Dr. Haworth was the recipient of D. Sc. degrees from Indiana University and Bucknell University and a D. Eng. degree from Stevens Institute of Technology in 1961. He was also awarded a D. Sc. by the University of Wisconsin in 1962. In 1964 Dr. Haworth received an honorary doctor of civil laws from Union College, Schenectady, N.Y., and a doctor of laws from Rider College, Trenton, N.J.

The list of special scientific committees and project groups that Dr. Haworth has served on include Project Vista, U.S. Army, 1951; the ad hoc committee on combat developments, U.S. Army, 1954; Technological Capabilities Panel of the President's Science Advisory Committee, 1954; member and Chairman of the NSF Advisory Panel on High Energy Accelerators, 1954 to 1961; and Project Atlantis of the U.S. Navy, 1959. He was a member of the board of directors of the American Nuclear Society, 1955–60, and president, 1957–58. He is a fellow of the American Physical Society, American Nuclear Society, and the New York Academy of Sciences. Dr. Haworth is also a member of the Cosmos Club, Sigma Xi, Gamma Alpha, Phi Beta Kappa, and Lambda Chi Alpha. He received a certificate of merit from the President of the United States for his World War II research. Dr. Haworth represents the Foundation on the Federal Council for Science and Technology and the Defense Science Board of the Department of

Defense. Dr. Haworth also serves as a member of the President's Committee on Manpower and as a consultant to the President's Science Advisory Committee.

Scientific specialties which are of interest to Dr. Haworth include the study and research in surface structure of metals, secondary electron emission, low-temperature research, nuclear physics, high energy physics, very high energy accelerators, and electronics. He has written numerous scientific papers and is the author of several chapters of the MIT Radiation Laboratory technical series.

Dr. and Mrs. Haworth, the former Irene Benik, reside at 1600 South Joyce Street, Arlington, Va. Dr. Haworth has two children by his marriage to the late Barbara Mottier Haworth—Barbara Jane and John Paul Haworth. Barbara Jane resides in Arlington, Va., and John Paul is a resident of Redondo Beach, Calif.

DR. EDWARD PENDLETON HERRING

Herring, Dr. (Edward) Pendleton, Social Science Research Council, 230 Park Avenue, New York, N.Y. American Government. Baltimore, Md., Oct. 27, 03; m. 33; c. 2. A.B., Hopkins, 25, Ph. D., 28' hon. A.M. Harvard, 44. REV. THEODORE M. HESBURGH, C.S.C.

Rev. Theodore M. Hesburgh, C.S.C., has been president of the University of Notre Dame since 1952. In addition to his many responsibilities as the head of one of America's leading universities, Father Hesburgh holds several important posts in the interrelated areas of education, science, Government, and public affairs.

By Presidential appointment, Father Hesburgh is a member of the U.S. Commission on Civil Rights, the U.S. Advisory Commission on International, Educational, and Cultural Affairs and the National Science Board. As chairman of the Board's Committee on International Science Activities, he visited the U.S. research centers in the Antarctic and at the South Pole in 1962. By appointment of Pope Paul VI and his two predecessors, Father Hesburgh has served since 1957 as permanent representative of the Holy See to the International Atomic Energy Agency in Vienna. He is president of the International Federation of Catholic Universities and a former president of the Association of American Colleges (1961). He is a trustee of the Rockefeller Foundation and a consultant to the State Department's Policy Planning Council.

For his leadership in American higher education and tireless public service, Father Hesburgh was named by President Johnson to receive the Medal of Freedom, the highest civil honor the President can bestow. The presentation took place at a White House ceremony on September 14, 1964.

Father Hesburgh was appointed 16th president of the University of Notre Dame at the age of 35 in June 1952. His administration has been one of the greatest periods of physical growth and internal academic development in the university's 123-year history. Today he heads an institution with a beautiful campus of 1,000 acres, a distinguished faculty of 523 scholars and artists and a record enrollment of 6,983 students from every State in the Union and 44 foreign countries.

Since Father Hesburgh's elevation to the presidency, Notre Dame has erected 20 major buildings including the 13-story, $9 million Notre Dame Memorial Library which opened in September 1963. Among the newer structures are a $3 million computing center and mathematics building; a $2,200,000 radiation

research building, erected by the U.S. Atomic Energy Commission; a $1,500,000 center for continuing education; Lewis Hall, a $1 million graduate residence for nuns; and the Stepan Center.

The new library, believed to be the largest college library building in the world, was the focal point of a 3-year, $18 million Notre Dame development program which was completed successfully in June 1963. Early in 1964, the university inaugurated its $20 million Challenge II program, earmarking $6,500,000 for faculty development and new academic programs; $5,500,000 for student aid; $5 million for an athletic and convocation center; and $3 million for two undergraduate residence halls. In each of these two major development efforts, Notre Dame received a $6 million matching grant from the Ford Foundation as one of the original five participants in its special program in education.

During Father Hesburgh's presidency a freshman year of studies and a sophomore year of studies were created—the latter Notre Dame's first foreign study program in Innsbruck, Austria. Another will be initiated in Angers, France, in 1966. New curriculums were established in the Notre Dame Law School, the college of arts and letters, and the college of business administration, and a comprehensive self-study was completed in the college of engineering. During the same 13-year period professors' salaries have been increased substantially, and a number of internationally recognized scholars have been added to the faculty. Father Hesburgh has encouraged a marked development of student government at Notre Dame, stressing the importance of personal responsibility in campus life. There has been a steady increase in the number of Notre Dame seniors winning graduate fellowships in nationwide competition. During the years 1960–63, Notre Dame ranked 10th among the Nation's private universities in the number of Woodrow Wilson, National Science Foundation, and National Defense Education Act fellowships won by its students (121).

Throughout his administration Father Hesburgh has reaffirmed Notre Dame's conviction that it is not enough for a university to develop mere professional competence in its students. Consequently, whether educating students in the liberal and fine arts, science and engineering, or business administration and law, Notre Dame endeavors to instill in its students a sense of moral responsibility which they retain throughout life.

Prior to becoming Notre Dame's president in 1952, Father Hesburgh served for 3 years as executive vice president of the university. During 1948–49 he was head of the theology department. He is the author of "Patterns for Educational Growth" and "God and the World of Man," a widely used college text. Several of his major addresses in recent years have been published in "Thoughts for Our Times" and "More Thoughts for Our Times."

Father Hesburgh has been associated with several educational, scientific, and cultural organizations in addition to those previously mentioned. He is a former director of the American Council on Education and currently is a member of the National Commission on the Humanities. He is a trustee of the Carnegie Foundation for the Advancement of Teaching and served as its president during 1963–64. A former vice president of the Institute of International Education, he is a member of its board of directors, having been chairman of its national advisory committee on Africa and head of its national advisory committee for Fulbright grants.

Identified with the international atoms-for-peace program from the outset, Father Hesburgh was for several years a director of the Midwest Universities Research Association, which unites 15 campuses in a project of high-energy physics, and a member of the Policy Advisory Board of Argonne National Laboratory.

Notre Dame's president is a director of the Woodrow Wilson National Fellowship Corp., the Nutrition Foundation, the Freedom Foundation, and Educational Services, Inc., of MIT. He is a member of the Advisory Council of the Institute of European Studies and the advisory boards of the National Students Association and the National Federation of Catholic College Students as well as cochairman of the National Catholic Conference for Interracial Justice.

Father Hesburgh has been an early and enthusiastic booster of the Peace Corps and was instrumental in establishing a Peace Corps unit in rural Chile. A fellow of the American Academy of Arts and Sciences, he holds the U.S. Navy's Distinguished Service Medal and has been honored by 16 colleges and universities in this country and abroad. Institutions which have conferred honorary degrees on Notre Dame's president include Columbia University, Princeton University,

Dartmouth College, Northwestern University, Indiana University, Brandeis University, University of California at Los Angeles, the University of Rhode Island, Temple University, Villanova University, Bradley University, Gonzaga University, Lafayette College, LeMoyne College, St. Benedict's College, and the Catholic University of Santiago, Chile.

Father Hesburgh was educated at Notre Dame and the Gregorian University in Rome where he received a bachelor of philosophy degree in 1939. He was ordained a priest of the Congregation of Holy Cross in Sacred Heart Church on the Notre Dame campus June 24, 1943, by the late Archbishop John F. Noll, of Fort Wayne. Following his ordination, Father Hesburgh continued his study of sacred theology at the Catholic University of America, Washington, D.C., receiving his doctorate (S.T.D.) in 1945. He joined the Notre Dame faculty the same year.

Born in Syracuse, N.Y., May 25, 1917, Notre Dame's president is the son of Anne Murphy Hesburgh and the late Theodore Bernard Hesburgh, an official of the Pittsburgh Plate Glass Co. A brother, James Hesburgh, was graduated from Notre Dame in 1955 and Harvard (M.B.A.) in 1900 and is vice president of the Wheelabrator Corp., Mishawaka, Ind. Father Hesburgh has two sisters, Mrs. Robert O'Neill, Cazenovia, N.Y., and Mrs. John Jackson, Syracuse, N.Y. A third sister, Mrs. Alton Lyons, of Oneida, N.Y., died in 1957.

DR. J. HERBERT HOLLOMON

Degrees: B.S., physics, Massachusetts Institute of Technology, 1940; D. Sci., metallurgy, Massachusetts Institute of Technology, 1946; Ph. D., engineering, Worcester Polytechnic Institute (honorary), 1964; Ph. D., engineering, Michigan Technological University (honorary), 1965.

Relations with education: Instructor, Harvard School of Engineering, 1940–41; adjunct professor, Rensselaer Polytechnic Institute, 1950–62. Adviser: Cornell School of Engineering, 1958– ; Harvard School of Engineering and Applied Science, 1959– ; and Massachusetts Institute of Technology.

Military: Active duty, 1941–46, research, physical metallurgy, Watertown Arsenal, final rank: Major.

Industry: General Electric Co., 1946–52; research, metallurgy, General Electric Research Laboratory, 1952–60; manager, metallurgy and ceramics research, 1952–60; general manager, General Engineering Lab, 1960–62.

Author: Textbook on metallurgy; more than 100 articles in professional journals.

Editor: Technical book series published by John Wiley Co.

Technical societies: Fellow, American Physical Society; former director of metallurgy, Institute for Mining, Metallurgical & Petroleum Engineers (AIME); former trustee, American Society for Metals (ASM); American Association for the Advancement of Science; Society for the History of Technology; and American Society of Mechanical Engineers.

Honorary societies: Sigma Xi, American Academy of Arts and Sciences, National Academy of Engineering (founding member), and New York Academy of Sciences (fellow).

Awards: Leadership, Kappa Sigma Fraternity, 1940; Raymond W. Rossiter Award of the American Institute of Mechanical Engineers; Alfred Noble Award of the Combined Engineering Societies; the Rosenhain Medal, Great Britain's Institute of Metals (first receipient from the United States); Army Legion of Merit; selected as 1 of the 10 outstanding scientists in the Nation by Fortune and by the National Junior Chamber of Commerce, 1954.

DR. DONALD F. HORNIG

Dr. Donald F. Hornig was born in Milwaukee in 1920, the son of C. Arthur Hornig and the former Emma Knuth. In 1943 he married Lilli Schwenk and they have four children, Joanna, Ellen, Christopher, and Leslie.

Dr. Hornig became Special Assistant to President Johnson for Science and Technology on January 24, 1964. He was simultaneously named by the President to be Chairman of the Federal Council for Science and Technology. On January 27, 1964, the Senate confirmed Dr. Hornig as Director of the Office of Science and Technology in the Executive Office of the President. Dr. Hornig also serves as the Chairman of the President's Science Advisory Committee.

A graduate of Harvard University, where he received his B.S. degree in 1940 and his Ph. D. in chemistry 3 years later, he was awarded a Guggenheim grant and a Fulbright scholarship for research at St. John's College, Oxford University, England, in 1954–55, and in the same year was appointed the first Bourke overseas lecturer by the Faraday Society of London.

After receiving his doctorate at Harvard, Dr. Hornig spent a year as a research associate at the Woods Hole Oceanographic Institution. From 1944 to 1946 he was a group leader at Los Alamos Laboratory and in the latter year joined the faculty at Brown as assistant professor. Three years later he became an associate professor and Director of the Metcalf Research Laboratory. He was promoted to the rank of professor in 1951 and the following year became associate dean of the graduate school. Subsequently he was acting dean. He was appointed chairman of his department at Princeton in 1958. Dr. Hornig was the first incumbent of the Donner Chair of Science at Princeton established in 1958 by the Donner Foundation, Inc.

Dr. Hornig has been an associate editor of the Journal of Chemical Physics and is a member of the Editorial Advisory Boards of Spectrochimica Acta and Molecular Physics. He was president, from 1945–47, of Radiation Instruments Co.; chairman of Project Metcalf, Office of Naval Research in 1951–52. He was a member of the Advisory Committee, Office of Scientific Research, U.S. Air Force. In 1959 he was appointed to the Space Science Board of the National Academy of Sciences on which he served until February of 1964. In 1960 he was appointed by President Eisenhower to the President's Science Advisory Committee and was reappointed by President Kennedy in 1961. In late 1960 he served on the Kennedy task force on space to help formulate policy in this field for the new administration.

In 1962–63 Dr. Hornig was a member of the delegation headed by Dr. Hugh Dryden which negotiated the agreement with the U.S.S.R. for cooperation in certain space activities.

Dr. Hornig was elected in 1954 to a 3-year term on the executive committee, Division of Physical and Inorganic Chemistry, American Chemical Society. He is also a fellow of the American Physical Society (member, executive committee, Division of Chemical Physics, and chairman, 1957–58); a fellow of the American Academy of Arts and Sciences, and of the Faraday Society, London. He was elected to the National Academy of Science in 1957 and in 1964 was named a member of the board of overseers of Harvard University. He was elected an honorary member of the Rumanian Academy of Sciences in February 1965.

Dr. Hornig has published about 70 papers in the Journal of Chemical Physics, Journal of the Optical Society of America, Journal of Physical Chemistry, Review of Scientific Instruments, Physics of Fluids, Molecular Physics, Spectrochimica Acta, Discussions of the Faraday Society on molecular and crystal structure, infrared and Raman Spectra, shock and detonation waves, relaxati on phenomena and fast chemical reactions at high temperatures.

In 1964 Dr. Hornig was awarded an honorary LL.D. by Temple University, and an honorary doctor of humane letters from Yeshiva University in New York in March of 1965.

FRANCIS KEPPEL

U.S. Commissioner of Education Francis Keppel, came to the U.S. Office of Education from the position of dean of the Graduate School of Education, Harvard University. He served in that capacity from 1948 until his appointment to the commissionship in December 1962.

During his tenure as Harvard's dean of the graduate school of education, Mr. Keppel served in numerous advisory and consultant capacities on the national and international scene, including an educational commission for the Nigerian Government in 1960. As Commissioner of Education he is a member of the U.S. National Commission for UNESCO and of the Board of Foreign Scholarships, and served as Deputy Chairman of the U.S. Delegation to the Third Inter-American Meeting of Ministers of Education, Bogotá, Colombia, in August 1963.

Mr. Keppel was born April 16, 1916, in New York City where his father, the late Frederick P. Keppel, was dean of Columbia College and later president of the Carnegie Corp. He received his A.B. degree from Harvard in 1938 and studied sculpture for a year at the American Academy in Rome.

Mr. Keppel continued his studies while serving as an assistant dean at Harvard College from 1939 to 1941. During World War II, he was secretary of the Joint Army and Navy Committee on Welfare and Recreation (1941–44); he served in the U.S. Army 1944–46, rising from private to 1st lieutenant. He then returned to Harvard where for the next 2 years he was assistant to the provost prior to being named dean of the graduate school of education. In the latter capacity, he directed programs for the preparation of school teachers, administrators, and other educational specialists, and guided research activities.

Mr. Keppel is a fellow of the American Academy of Arts and Sciences. He was married in 1941 to Edith Moulton Sawin. They have two children, Edith Tracy (Mrs. Samuel S. Drury, Jr.) and Susan Moulton.

DR. CHARLES KIMBALL

Dr. Charles Kimball has been president of Midwest Research Institute since June of 1950. MRI is an independent, not-for-profit organization with a staff of 350 persons engaged in contract research and development in chemistry, economics, physics, engineering, biology, and related science and technology programs for industrial and government sponsors.

Dr. Kimball is a native of Boston. After undergraduate work in electrical engineering at Northeastern University, he received his master's and doctor's degrees from Harvard University. He has received honorary degrees from Northeastern, Park College, and Parsons College.

Before coming to MRI, Dr. Kimball was technical director of the Research Laboratories Division of the Bendix Corp., Detroit. Earlier he was a research engineer for RCA, taught in the Graduate School of New York University, and served as vice president and director of Aircraft Accessories Corp.

Dr. Kimball is a member of the board of directors of Trans World Airlines and of Hallmark Cards, Inc. He is a trustee of the Committee for Economic Development (CED), the Hallmark Foundation, the Menninger Foundation, and the University of Kansas City, and is on the board of regents of Rockhurst College. He is a fellow of the Institute of Electrical and Electronics Engineers, and a member of Tau Beta Pi and the American Association for the Advancement of Science.

He is the author of many articles in scientific journals and in business and management publications. He is an ardent amateur artist and greatly interested in educational opportunities for young people.

DR. JAMES RHYNE KILLIAN, JR.

Dr. James R. Killian, Jr., became chairman of the Corporation of the Massachusetts Institute of Technology on January 1, 1959, after nearly 10 years as president. The period of his presidency was marked by great expansion of the institute, by increasing research, including responsibilities for defense research, and by more emphasis on the humanities and social sciences in the education of scientists and engineers.

For a number of years Dr. Killian has been one of the leading spokesmen in behalf of better schools, the importance of science in liberal education, the strengthening of engineering education, and greater attention to basic research. Speaking as an educator, he has been a protagonist for the advancement of science and engineering as a national goal of prime importance.

From November 1957, to July 1959, Dr. Killian was on leave from MIT, serving as Special Assistant for Science and Technology to President Eisenhower, a key position at a time when government, science, and industry required special leadership in the search for solutions to problems of worldwide importance.

Dr. Killian was born in Blacksburg, S.C., on July 24, 1904, the son of the late James Robert and Jeannette (Rhyme) Killian and a descendent of Andreas Killian, who came from Germany to Pennsylvania and in 1749 emigrated to Catawba County, N.C. His father was a textile manufacturer.

After attending the McCallie School in Chattanooga, Tenn., he studied at Trinity College (now Duke University) from 1921 to 1923, when he transferred to MIT. He was a member of the class of 1926 and received the degree of bachelor of science in business and engineering administration. He remained at the institute to become assistant managing editor of the Technology Review, alumni magazine. He became managing editor in 1927 and served as editor from 1930 to 1939, when he was made executive assistant to the president of MIT, Dr. Karl Taylor Compton.

During World War II, when Dr. Compton was one of the Nation's leaders in the application of science to the war effort, and when MIT was undertaking a number of special Government projects, Dr. Killian carried much of the burden of administering the institute's complex affairs. He was appointed executive vice president in July 1943, and was elected vice president in December 1945. At the age of 45, in April 1949, Dr. Killian became president, and Dr. Compton became chairman, of the corporation.

Under Dr. Killian's leadership, MIT has been active in increasing its financial resources, not only to meet current needs, but also, through long-range plans, to provide for continual advancement in education and research.

A stanch advocate of more general education—more basic science as well as more humanities and social science—in the engineering curriculum, Dr. Killian has contended that the problem is to provide a common core of studies which will contribute toward a man's effectiveness as an individual and a citizen, regardless of his occupation.

Dr. Killian, therefore, consistently supported changes to balance the institute's professional curriculum with such courses, activities, and environment as would give the graduate intellectual depth as well as breadth. He maintained that not only does the scientific environment stimulate first-rate work in social science, but also that the presence of such a program enables MIT to turn out more efficient scientists and engineers and citizens better qualified to serve their fellows.

Early in his administration, the institute, in response to a recommendation of a faculty committee formed at his suggestion, established a school of humanities and social studies. The institute was further helped to play its rightful role in the development of potential leaders for industry when, in 1952, a school of industrial management was established through gifts of $6,250,000 from the Alfred P. Sloan Foundation, Inc. The center for international studies is another important unit of MIT established during Dr. Killian's presidency. These extensions of the MIT program were all contributory to the creation of a new kind of university which Dr. Killian has described as a "university polarized around science".

Dr. Killian has an extensive record of service to the Government. He served from 1956 to 1957 and from 1959 to 1961 as chairman of the board of trustees, and he continues as a trustee of the Institute for Defense Analyses, an organization set up by MIT and four other universities for applying scientific methods and analysis to military problems. He was a member of the Science Advisory Committee of the Office of Defense Mobilization, 1951–57, and when this committee became the President's Science Advisory Committee late in 1957, Dr. Killian became its Chairman and served that post until July 1959. In 1961 President Kennedy appointed him consultant at large to the committee. He was a member of the President's Communications Policy Board, 1950–51; the President's Advisory Committee on Management, 1950–52; the Board of Visitors of the U.S. Naval Academy, 1953–55; the Committee for the White House Conference on Education, 1954–56; and was chairman of the Army scientific advisory panel from 1951–56. In 1960 he served as a member of the President's Commission on National Goals. Dr. Killian recently retired as Chairman of the President's Foreign Intelligence Advisory Board after 2 years of service. During the Eisenhower administration he served as the first chairman of a similar board.

Dr. Killian was a director of the Federal Reserve Bank of Boston from 1954–57. He is a trustee of the Alfred P. Sloan Foundation, the Mellon Institute, the U. S. Churchill Foundation, Mount Holyoke College, the Boston Museum of Science, the Mitre Corp., and the Nutrition Foundation. He is a member of the board of American Telephone & Telegraph, the Cabot Corp., General Motors Corp. and the Polaroid Corp. Dr. Killian was a member of the board of trustees of the Carnegie Foundation for the Advancement of Teaching from 1957 to 1958. From 1955 to 1958 he served as president of Atoms for Peace Awards, Inc., and he was elected to this office again in 1959. He was moderator of the American Unitarian Association from 1960–61. Also active in his own community, Dr. Killian is a member of the Board of Education of the Commonwealth of Massachusetts and is chairman of the Cambridge (Mass.) Citizens Advisory Committee.

He has been the recipient of a number of honorary degrees: LL. D., Union College, 1947; Bowdoin College, 1949; Northeastern University, 1949; Duke University, 1949; Boston University, 1950; Harvard University, 1950; Williams College, 1951; Lehigh University, 1951; University of Pennsylvania, 1951; University of Chattanooga, 1954; Tufts University, 1955; University of California, 1956;

Amherst College, 1956; College of William and Mary, 1957; Brandeis University, 1958; New York University and Johns Hopkins, 1959; Providence College, 1960; Temple University, 1960; University of South Carolina, 1961; Meadville Theological School, 1962; Sc. D., Middlebury College, 1945; Bates College, 1950; University of Havana, Cuba, 1953; Notre Dame University, 1954; Lowell Technological Institute, 1954; Columbia University, 1958; College of Wooster, 1958; Oberlin College, 1958; University of Akron, 1959; Worcester Polytechnic Institute, 1960; University of Maine, 1963; D. Eng., Drexel Institute of Technology, 1948; University of Illinois, 1960; University of Massachusetts, 1961; D. Appl. Sci., University of Montreal, 1958; Ed. D., Rhode Island College, 1962; HH. D., Rollins College, 1964.

Dr. Killian received the President's Certificate of Merit in 1948; the Certificate of Appreciation, Department of the Army, 1953; and the Decoration for Exceptional Civilian Service, Department of the Army, 1957; the Public Welfare Medal of the National Academy of Sciences, 1957; Officer, French Legion of Honor, 1957; the Gold Medal of the National Institute of Social Sciences, 1958; World Brotherhood Award of the National Conference of Christians and Jews, 1958; Award of Merit of the American Institute of Consulting Engineers, 1958; Washington Award, Western Society of Engineers, 1959; Distinguished Achievement Award, Holland Society of New York, 1959; the Gold Medal of the International Benjamin Franklin Society, 1960; and the Good Government Award, Crosscup-Pishon Post, American Legion, 1960; Hoover Medal, 1963. He was elected honorary member of the American Society for Engineering Education in 1963. A fellow of the American Academy of Arts and Sciences, and Overseas Fellow of Churchill College, England. Dr. Killian is also a member of Sigma Chi and an honorary member of Phi Beta Kappa and Tau Beta Pi. His clubs include the Metropolitan (Washington), the Club of Odd Volumes, St. Botolph, Union and Algonquin (Boston), the Century (New York City) and the University (Boston, New York City).

Dr. Killian was married in 1929 to Miss Elizabeth Parks of Asheboro, N.C., a graduate of Wellesley College. They have one daughter, Carolyn (Mrs. Paul R. Staley), and a son, Rhyne Meredith Killian.

WILLIAM T. KNOX

Mr. William T. Knox was born in Social Circle, Ga., on August 24, 1917. He has been with the Esso Research & Engineering Co., of Linden, N.J., since 1938, progressing from research chemist through manager, technical information division, in 1957, to manager, corporate planning, in 1962.

Mr. Knox has been a consultant on technical information matters to the National Science Foundation, the Office of Science and Technology, the Engineers Joint Council, and the Department of Defense.

In September 1964 Mr. Knox joined the staff of the Office of Science and Technology in the Executive Office of the President, assuming responsibility for stimulating development of more effective scientific and technical information systems. His new responsibilities also include broad questions of research management.

Mr. Knox holds several patents and has authored many articles on petroleum engineering and on information research and management.

Mr. Knox, his wife, Celia, and their three children, are residents of Cranford, N.J.

DR. LEONARD A. LECHT

Leonard A. Lecht is director, national goals project, National Planning Association. Ph. D., Columbia University, 1953. Taught at University of Texas, 1949–53, Carleton College, 1953–54. Chairman, Department of Economics, Long Island University, 1954–62. Since 1962, director, national goals project, NPA. Author: "Experience Under Railway Labor Legislation," 1955; (with G. Colm) "Requirements for Scientific and Engineering Manpower in the 1970's," 1964; "The Dollar Cost of our National Goals," 1965. Member, American Economic Association, Phi Beta Kappa, Royal Economic Society.

DR. HOMER E. NEWELL

Dr. Homer E. Newell is Associate Administrator for Space Science and Applications in NASA Headquarters. He was the Director of the Office of Space Sciences from November 1, 1961, until he assumed his present position November 1, 1963. Previously he was Deputy Director, Space Flight Programs.

As head of the Office of Space Science and Applications, Dr. Newell administers the following NASA program areas: bioscience, communication and navigation, lunar and planetary, meteorological, manned space science, grants and research contracts, geophysics and astronomy, and launch vehicles and propulsion.

An internationally known authority in the field of atmospheric and space sciences, he is the holder of the American Rocket Society's Pendray Award for 1958; the 1960 Space Flight Award, granted annually by the American Astronautical Society to the person who contributed most to the advancement of astronautical sciences; and the AMVETS Civil Servant of the Year Award for 1961.

He joined NASA in October 1958 from the U.S. Naval Research Laboratory where he was Acting Superintendent of the Atmosphere and Astrophysics Division. In this position he was also the Science Program Coordinator for Project Vanguard, the U.S. scientific earth satellite program for the International Geophysical Year.

Dr. Newell was born in Holyoke, Mass., and earned both B.A. and M.A. degrees in teaching at Harvard University and a Ph.D. in mathematics at the University of Wisconsin in 1940. He was awarded a doctor of science (honorary) degree by Central Methodist College, Fayette, Mo., on September 6, 1963.

From 1940 to 1944 he was an instructor and later assistant professor of mathematics at the University of Maryland, and a ground instructor in navigation with the Civil Aeronautics Administration from 1942 to 1943. From 1951 to 1958, as lecturer in mathematics for the University of Maryland, Dr. Newell participated in the NRL—University of Maryland off-campus education program by teaching graduate courses in mathematics to NRL and other Government employees.

Dr. Newell joined the Naval Research Laboratory in 1944, and became head of the Rocket Sonde Branch in 1947. In this position, he was in charge of the upper atmosphere research program of the NRL. In 1955 he was named Acting Superintendent of the Atmosphere and Astrophysics Division.

His scientific committee memberships have included the Special Subcommittee on the Upper Atmosphere of the National Advisory Committee for Aeronautics (1947–51), and the Rocket and Satellite Research Panel (formerly Upper Atmosphere Rocket Research Panel) since 1947. He was chairman of the Rocket and Satellite Research Panel in 1959 and 1960. He was a member of the National Academy of Sciences' Panels on Rocketry and the earth satellite program for the IGY, and was chairman of a special committee of the rocketry panel for planning and organizing this country's IGY sounding rocket program at Fort Churchill in Canada. In addition, Dr. Newell serves on several committees and working groups of the Committee on Space Research of the International Council of Scientific Unions, of the International Union of Geodesy and Geophysics, and of the International Scientific Radio Union.

Dr. Newell is the author of numerous scientific articles and seven books ranging from technical works to popular treatments of space science and rockets. He is a member of Phi Beta Kappa, Sigma Xi, and the Cosmos Club. In addition, he holds membership in the following professional societies, American Association for the Advancement of Science (fellow), American Institute of Aeronautics and Astronautics, Research Society of America, and the American Geophysical Union (fellow). He served as president of the Planetary Sciences Section of the American Geophysical Union during the period 1962–64.

Dr. Newell, his wife, and son, Andrew, reside in Washington D.C. They have three married daughters.

HERMAN POLLACK

Mr. Pollack was born in New York City on October 22, 1919. He received his undergraduate degree at the City College of New York and, while holding a fellowship in the department of government at CCNY, did graduate work at Columbia University.

Mr. Pollack began his Government service career in 1941 with the Office of Price Administration where he served in a variety of assignments in the personnel field. Following a period of service in the U.S. Army, Mr. Pollack served with War Shipping Administration and the Foreign Economic Administration.

Since October 1946, Mr. Pollack has served with the Department of State. Among the positions he has held with the Department are: Deputy Executive

Director and Acting Executive Director, Bureau of European Affairs; Executive Assistant, Office of the Assistant Secretary for Administration; Director of the Management Staff; and the Deputy Assistant Secretary of Personnel. He attended the National War College in 1963–64 and was appointed Deputy Director. Office of International Scientific Affairs on September 13, 1964, and Acting Director on January 1, 1965.

DR. DON K. PRICE

Born: Middlesboro, Ky., January 23, 1910.

Education: A.B., Vanderbilt University, 1931; B.A., Oxford University (Rhodes scholar 1932), 1934; B. Litt., 1935; LL.D., Centre College of Kentucky, 1961; Syracuse University, 1962.

Married: Margaret Helen Gailbreath, March 3, 1936; children: Don C., Linda G. (Mrs. Keith S. Thomson).

Reporter, Nashville Evening Tennessean, 1930–32.

Staff, Home Owners' Loan Corporation, 1935–37; Social Security Research Council, 1937–39; Public Administration Clearing House, 1939–53; U.S. Bureau of the Budget, 1945–46; Hoover Commission on the Organization of the Executive Branch of Government, 1947–48; Deputy Chairman, Research and Development Board, U.S. Department of Defense, 1952–53.

Associate director, 1953–54, vice president 1954–58, Ford Foundation.

Dean, Graduate School of Public Administration, Harvard University, 1958– .

Served as lieutenant, U.S. Coast Guard Reserve, 1943–45.

Member, President's Advisory Committee on Government Organization, 1959–61; Committee on Foreign Affairs Personnel (Carnegie Endowment) 1961–63; President's Advisory Panel on Federal Salary System, 1962–63; President's Advisory Panel on a National Academy of Foreign Affairs, 1962–63; Consultant to the Executive Office of the President, 1961– ; Chairman President's Task Force on Government Organization, 1964; trustee, the Rand Corp.; Vanderbilt University; the Twentieth Century Fund; Director, Social Science Research Council.

Author: "City Manager Government in the United States" (with Harold and Kathryn Stone), 1940; "U.S. Foreign Policy, Its Organization and Control" (with W. Y. Elliott and others), 1952, also "The Political Economy of American Foreign Policy," 1955; "Government and Science," 1954; ed., "The Secretary of State" (for the American Assembly), 1960; "The Scientific Estate," 1965.

DR. ISIDOR ISAAC RABI

My name is Isidor Isaac Rabi. I am at present university professor at Columbia University in New York City. I am also consultant-at-large on the President's Scientific Advisory Committee, a member of the Naval Research Advisory Committee, a member of the Board of Trustees of Associated Universities, Inc., for both Brookhaven National Laboratory and the National Radio Astronomy Observatory. I have been the U.S. representative on the United Nations Science Committee since its inception in 1954. This Committee has been responsible for the formulation of the three Geneva Conferences on the Peaceful Uses of Atomic Energy as well as the Conference on the Application of Science and Technology for the Benefit of Less Developed Areas in Geneva in 1963. I am also the U.S. member of the NATO Science Committee, and a consultant to the International Atomic Energy Agency and to the U.S. Atomic Energy Commission.

I am a graduate of Cornell University with a B. Chem., 1919; and of Columbia University Ph. D. in physics, 1927.

I am a fellow of the American Physical Society, president during 1950–51, a member of the National Academy of Science and the American Philosophical Society.

During the war I was an Associate Director of the Radiation Laboratory in Cambridge, Mass. and consultant to the Los Alamos Scientific Laboratory. I was a member of the General Advisory Committee to the Atomic Energy Commission for 10 years and Chairman for 4 years. At present, I am a member of the General Advisory Committee to the Arms Control and Disarmament Agency.

Since the end of the war I have interested myself in the application of the universal nature of science in creating stronger bonds between the United States and the nations of the world in order to further peaceful, equitable solutions to the problems of international tension.

DR. S. DILLON RIPLEY

S. Dillon Ripley, biologist and authority on birds of the Far East, is the eighth Secretary of the 119-year-old Smithsonian Institution.

Following in the Smithsonian's tradition of scholarly leaders, Dr. Ripley was appointed chief executive of the Institution on February 1, 1964, after serving for 4 years as director of Yale University's Peabody Museum of Natural History.

He also has served on the staffs of the Academy of Natural Sciences in Philadelphia, the American Museum of Natural History in New York, and Harvard University.

Self-described as an "old-fashioned naturalist of the Darwin school," Professor Ripley was only 13 when he hiked through western Tibet studying birds. At the age of 17, with his family's help, he constructed a small duck pond, and since that time has spent 34 years in observing and collecting waterfowl.

The Smithsonian Museum of Natural History has among its research collections more than 3,000 birdskins collected by Mr. Ripley on field trips to the South Pacific, Ceylon, India, and Nepal.

Today, at 51 years of age, he has written six books on ornithological studies, including "A Paddling of Ducks," "Search for the Spiny Babbler," "Trail of the Money Bird," and his most recent, "Land and Wildlife of Tropical Asia."

During World War II, Dr. Ripley served as a civilian attached to the Office of Strategic Services (OSS).

A native of New York City and a 20-year member of its famed Explorers Club, he holds degrees from Yale University and Harvard University. In addition to numerous academic honors, he has received decorations from foreign countries, including the Order of the White Elephant from the Government of Thailand.

A member of several distinguished honorary and professional organizations, Dr. Ripley is president of the International Council for Bird Preservation. He also is an officer of the American Ornithologists' Union and serves on the Council of the International Union for the Conservation of Nature and Natural Resources.

Shortly after his appointment as Secretary of the Smithsonian, Dr. Ripley was named by President Johnson to the National Council on the Arts. He also is vice president of the American Association of Museums and a trustee of the Winterthur Museum.

In his post as chief administrative officer of the Smithsonian, Secretary Ripley heads a staff of more than 2,000 employees charged with preserving and interpreting the scientific, historic, and cultural heritage of America.

The Secretary, who describes the Smithsonian as "a company of scholars," envisions the Institution's future role as "a center for research and scholarship." His programs are designed to use the Smithsonian's collections creatively and across disciplinary lines.

"Collections—of which the Smithsonian has millions in its vast museum-gallery complex—should be a tool; they should not rule you," Dr. Ripley has said.

Dr. Ripley is married and the father of three children.

DR. WALTER ORR ROBERTS

Walter Orr Roberts graduated from Amherst College, A.B., in 1938 and received his M.A. and Ph. D. from Harvard University in 1940 and 1943, respectively. He also holds honorary doctor of science degrees from Ripon College, Amherst College, Colorado College, and Long Island University.

From 1940 to 1960, Dr. Roberts was director of the High Altitude Observatory at Climax and Boulder, Colo. During that time, the observatory evolved from a one-man operation, affiliated with the Harvard College Observatory and the University of Colorado, to a research division of the National Center for Atmospheric Research (NCAR). Since 1960, Dr. Robert has been the director of NCAR and principal officer of its governing body, the University Corp. for Atmospheric Research, a 21-university, nonprofit corporation.

Dr. Roberts also held the following academic appointments: Instructor, Harvard University and Radcliffe College, 1947–48; associate of the Harvard College Observatory, 1948– ; professor of astrogeophysics, University of Colorado, 1957– , (currently on indefinite leave).

His memberships in professional societies include: American Astronomical Society, International Astronomical Union, American Geophysical Union (fellow), Royal Astronomical Society (fellow), American Meteorological Society,

American Institute of Aeronautics and Astronautics, and International Academy of Astronautics of the International Astronautical Federation.

Memberships in other societies include: Sigma Xi, American Academy of Arts and Sciences (fellow), and Aspen Society of Fellows of the Aspen Institute for Humanistic Studies.

Dr. Roberts is a member of the following boards and committees:

Advisory Committee of the World Meteorological Organization;

Inter-Union Commission on Solar-Terrestrial Relationships (ICSU);

Solar Physics Subcommittee of the Space Science Steering Committee of NASA;

Pacific Science Board of the National Academy of Sciences;

Geophysics Research Board of the National Academy of Sciences;

Advisory Committee on Atmospheric Water Resources, Bureau of Reclamation;

Board of directors, American Association for the Advancement of Science;

Panel 3 (scientific investigation of the Pacific Ocean), United States-Japan Committee on Scientific Cooperation;

AAAS Committee on the Public Understanding of Science (chairman);

Trustee of the MITRE Corp.;

Trustee of the Charles F. Kettering Foundation;

Trustee of Amherst College;

U.S. National Commission for UNESCO;

Board of directors, Fund for Overseas Research Grants and Education, Inc.

Present and past services include:

Editorial advisory board, Journal of Planetary and Space Science, 1958– ;

Associate editor, Journal of Geophysical Research, 1960–64;

Chairman, Solar Technical Panel of the U.S. National Committee for IGY, 1957–60;

Director, World Data Center A for Solar Activity, 1957–61;

Chairman, Colorado Weather Control Commission, 1958–60;

Member of Council, American Astronomical Society, 1960–63;

Member of Council, American Meteorological Society, 1960–63;

Member, ad hoc Committee on International Programs in Atmospheric Sciences and Hydrology of the National Academy of Sciences during 1962–63.

DR. JOHN E. SAWYER

Sawyer, John E(dward), coll. president; born Worcester, Mass., May 5, 1917; s. William Henry and Dorothy (Winslow) S.; A.B. Williams College, 1939; A.M. Harvard, 1941; LL.D. Amherst, Clark University 1961, Wesleyan University 1962, Middlebury College 1964; m. Anne W. Swift, June 28, 1941; Children—Katharine, John, Stephen W., William Kent. With Dept. State 1946; jr. fellow Soc. of Fellows, Harvard 1946–49; asst. prof. econ. history 1949–53; assoc. prof. econ. history Yale 1953–61; pres. of Williams College 1961– . Trustee Williams College; Ensign to lieutenant USNR 1942–46; with O.S.S. Washington and overseas; 1942–45; Recipient Bronze Star medal; Mem. Am. Hist. Assn.; Am. Econ. History Assn. (Trustee 1956–60) Am. Econs. Assn.; Phi Beta Kappa, Author articles profl. jours.; Home: 212 Main Street, Williamstown, Mass.

(From: Who's Who in America, vol. 33, 1964–65.)

DR. GLENN THEODORE SEABORG

Dr. Glenn T. Seaborg was born in Ishpeming, Mich., on April 19, 1912, a son of H. Theodore and Selma Erickson Seaborg. At the age of 10 he moved with his family to Home Gardens, Calif., now a part of South Gate, near Los Angeles. From 1925 to 1929 he attended David Starr Jordan High School in Los Angeles, graduating in 1929 as valedictorian of his class. It was in high school that Dr. Seaborg's interest in chemistry and physics was kindled by his science teacher, the late Dwight Logan Reid.

Dr. Seaborg entered the University of Califronia at Los Angeles in 1929. He was elected to Phi Beta Kappa, national honorary scholastic fraternity, in his junior year and received a bachelor of arts degree in chemistry from the university in 1934. In 1934 he entered the University of California at Berkeley where he received the degree of doctor of philosophy in chemistry in 1937. From 1937 to 1939, Dr. Seaborg was a research associate in chemistry on the Berkeley campus, working as the personal laboratory assistant of the late Dr. Gilbert

Newton Lewis, then dean of the college of chemistry, with whom he published a number of scientific papers.

In 1939, Dr. Seaborg was appointed an instructor in chemistry at the University of California, Berkeley. In this post, he became codiscoverer, in 1940, of element 94 (plutonium), the first of a number of transuranium elements which he was to help discover during the next 18 years. He was promoted to assistant professor of chemistry at the university in 1941 and in that year became codiscoverer of the nuclear energy isotope, plutonium 239. Also, in 1941, he helped to discover the uranium isotope U^{233}. In 1942, he was also codiscoverer at the university of the long-lived isotope of neptunium (element 93), neptunium 237 and of the existence in nature of plutonium in extremely small concentrations.

In April 1942, Dr. Seaborg was given a leave of absence from the University of California to head the plutonium work of the Manhattan project at the University of Chicago Metallurgical Laboratory. He remained at the laboratory until May 1946, as chief of the section working on transuranium elements. One of his principal responsibilities there was directing the development of the chemical process which was used for the separation of plutonium from fuel elements irradiated in the production reactors at the Hanford installation at Richland, Wash. While at the laboratory, Dr. Seaborg, with his associates, also discovered two more transuranium elements, element 95 (americium) and element 96 (curium), both in 1944.

In 1945, although still on leave from the University of California, Dr. Seaborg was promoted from assistant to full professor of chemistry at the university's Berkeley campus. In May 1946, he returned to the department of chemistry at the university and also took responsibility for direction of nuclear chemical research at the Lawrence Radiation Laboratory, operated for the Atomic Energy Commission by the university. In 1945 he was named associate director of the Laboratory, a position from which he resigned upon coming to the Commission.

In postwar research, Dr. Seaborg and his colleagues at the university discovered element 97 (berkelium) in 1949 and element 98 (californium) in 1950. In 1952, working with university scientists and scientists of the AEC's Argonne National Laboratory and of the Los Alamos Scientific Laboratory, he discovered element 99 (einsteinium) and, in 1953, element 100 (fermium). He was codiscoverer of element 101 (mendelevium) in 1955 and element 102 in 1958 at the University of California.

In addition to the discovery of transuranium elements, Dr. Seaborg and his colleagues are responsible for the identification of more than 100 isotopes of elements throughout the periodic table. He also is author of the actinide concept of heavy element electronic structure. In this connection, Dr. Seaborg demonstrated that the heavy elements form a "transition" series of actinide elements in a manner analagous to the rare earth series of lanthanide elements. The concept demonstrated how the heavy elements fit into the periodic table and thus demonstrated their relationships to the other elements.

The body of information assembled in Dr. Seaborg's laboratory has made it possible to predict the radioactive characteristics of many isotopes of elements still to be found. Under Dr. Seaborg's leadership, also, whole new bodies of methodology and instrumentation have been developed and have become a cornerstone of modern nuclear chemistry. Dr. Seaborg is the author of approximately 200 scientific papers, including a number of comprehensive reviews and compilations in scientific publications. He is also author and coauthor of several books on chemistry and the elements, including "Education and the Atom" (with D. M. Wilkes), a U.S. presentation volume at the Third International Conference on the Peaceful Uses of Atomic Energy, Geneva, Switzerland, 1964.

Dr. Seaborg was appointed by President Truman in 1946 to be a member of the Atomic Energy Commission's first General Advisory Committee, a post he held until 1950. He was a member of the Joint Commission on Radioactivity of the International Council of Scientific Unions from 1946 to 1956; of the Committee on Standards and Units of Radioactivity of the National Research Council from 1947 to 1951, and of the President's Science Advisory Committee from 1959 to 1961.

Among other honors, Dr. Seaborg was named, in 1947, as one of America's 10 outstanding young men by the U.S. Junior Chamber of Commerce, and in the same year was made recipient of the American Chemical Society's Award in Pure Chemistry. He was awarded the John Ericsson Gold Medal by the American Society of Swedish Engineers in 1948, and the Nichols Medal of the New York

Section of the American Chemical Society, also in 1948. With Prof. E. M. McMillan, of the University of California, he was awarded the Nobel Prize in Chemistry in 1951. He won the John Scott Award and Medal of the City of Philadelphia in 1953, and the Perkin Medal of the American Section of the Society of Chemical Industry in 1957.

Dr. Seaborg was named recipient in November 1959 of the Atomic Energy Commission's Enrico Fermi Award for his outstanding work in the field of nuclear chemistry and for his leadership in scientific and educational affairs. In 1962 he received an award at the semicentennial convocation at Rice University, Houston, Tex., and the Science and Engineering Award of the Federation of Engineering Societies of Drexel Institute of Technology in Philadelphia. He was named "Swedish American of the Year" by the Vasa Order of America in Stockholm, and was presented the Charles L. Harrison Award by the Cincinnati Post, American Ordnance Association in 1962. He received the Franklin Medal, given by the Franklin Institute of Philadelphia, in 1963.

In 1964 he was the first recipient of the Spirit of St. Louis Award, by the University of St. Louis, for pioneering achievements in a field that benefits mankind. Also in 1964 he was presented the Charles Lathrop Parsons Award for public service by the American Chemical Society. In January 1965, he was presented the Leif Erikson Award of the Leif Erikson Foundation of Los Angeles.

Dr. Seaborg is an honorary fellow of the Chemical Society of London and of the Royal Society of Edinburgh. He is a fellow of the American Institute of Chemists, the New York Academy of Sciences, the California Academy of Sciences, the American Physical Society and the American Association for the Advancement of Science. He is also a member of the American Chemical Society, American Nuclear Society, the American Academy of Arts & Sciences, the American Philosophical Society, the American Scandinavian Foundation, the National Academy of Sciences, the Royal Swedish Academy of Engineering Science, the Royal Society of Arts (England), the Society for the Advancement of Scandinavian Study, the American Swedish Historical Foundation, and an honorary member of the Society of Nuclear Medicine.

Honorary degrees awarded to Dr. Seaborg include doctor of science degrees from the University of Denver, 1951; Gustavus Adolphus College, 1954; Northwestern University, 1954; University of Notre Dame, 1961; Ohio State University, 1961; Florida State University, 1961; University of Maryland, 1961; Temple University, 1962; Tulane University, 1962; Drexel Institute of Technology, 1962; Georgetown University, 1962; the University of the State of New York, 1962; Mundelein College, 1963; and Trinity College, 1963; the degree of doctor of laws from the University of Michigan, 1958; and the University of Massachusetts, 1963; the degree of doctor of humane letters from Northern Michigan College, 1962; and Nebraska Wesleyan University, 1964; the degree of doctor of public service from George Washington University, 1962; and the degree of doctor of public administration from the University of Puget Sound, 1963.

In addition to his membership in Phi Beta Kappa, Dr. Seaborg also is a member of Sigma Xi, Pi Mu Epsilon, Alpha Chi Sigma, and Phi Lambda Upsilon fraternities.

Dr. Seaborg was a member of the board of directors, Nuclear Science & Engineering Corp., Pittsburgh, and a consultant for the U.S. Rubber Co. and Bell Telephone Laboratories. He is a member of the advisory board of the Journal of Inorganic and Nuclear Chemistry, a former member of the advisory board of Chemical and Engineering News and of the editorial board of the Journal of the American Chemical Society. He was a member of the board of directors of the National Educational Television & Radio Center, and of the National Committee on America's Goals & Resources of the National Planning Association.

He is chairman of the Steering Committee of the Chemical Education Material Study, sponsored by the National Science Foundation. He became a charter member of the Dag Hammarskjold Fellowship, Inc., in 1962. He also is a member of the Council on the Education of Teachers in Science of the National Science Teachers Association, as well as a member of the Commission on the Humanities of the American Council of Learned Societies, the Council of Graduate Schools, and the United Chapter of Phi Beta Kappa. He is a member of the Advisory Council on College Chemistry of the National Science Foundation.

In August 1958, Dr. Seaborg was appointed chancellor of the University of California at Berkeley. He served in that capacity until his appointment to the Atomic Energy Commission. He is currently considered by the University of California to be on leave from his post as professor of chemistry.

Dr. Seaborg was nominated to the Atomic Energy Commission by President Kennedy on January 21, 1961, and was confirmed by the U.S. Senate on February 24, 1961. He was designated Chairman of the Atomic Energy Commission by the President on March 1, 1961, which is also the date he took the oath of office. He succeeded former Chairman John A. McCone, who resigned as of January 20, 1961. Prior to the expiration of his term on June 30, 1963, Dr. Seaborg was reappointed by the President for a succeeding 5-year term, to expire on June 30, 1968. This appointment was confirmed by the U.S. Senate on June 24, 1963.

Dr. Seaborg served as the representative of the United States to the Fifth, Sixth, Seventh, and Eighth General Conferences of the International Atomic Energy Agency, Vienna, Austria, 1961, 1962, 1963, and 1964. In May 1963, he was chairman of the U.S. delegation to the U.S.S.R. for the signing of the "Memorandum on Cooperation in the Field of Utilization of Atomic Energy for Peaceful Purposes." In August 1963, he was a member of Secretary of State Rusk's delegation to Moscow for the signing of the Test Ban Treaty. In September 1964, President Johnson named Dr. Seaborg as chairman of the U.S. delegation to the Third International Conference on the Peaceful Uses of Atomic Energy, held in Geneva, Switzerland; Dr. Seaborg delivered the summary lecture at this conference.

As Chairman of the Atomic Energy Commission, Dr. Seaborg also serves as a member of the National Aeronautics and Space Council, the Federal Council for Science and Technology, the Federal Radiation Council, and the President's Committee on Equal Employment Opportunity.

On June 6, 1942, Dr. Seaborg married the former Helen L. Griggs, then secretary to the late Dr. Ernest O. Lawrence. The Seaborg's have six children: Peter, Lynne, David, Stephen, John Eric, and Dianne.

Dr. Seaborg's chief hobby is golf. His favorite spectator sport is football, although he follows baseball with interest. From 1953 to 1958 he served as the University of California (Berkeley) faculty athletic representative.

DR. FREDERICK SEITZ

Frederick Seitz was born in San Francisco, Calif., on July 4, 1911. After attending the public schools there, he entered Stanford University and graduated with an A.B. degree in mathematics in 1932. He earned a Ph. D. in physics at Princeton University in 1934 and remained there another year on a research fellowship. Since then he has been successively instructor in physics, 1935–36, and assistant professor, 1936–37, University of Rochester; research physicist, General Electric Co., 1937–39; assistant, then associate professor of physics, University of Pennsylvania, 1939–42; and professor and chairman of the physics department, Carnegie Institute of Technology, 1942–49. In 1949, he was appointed research professor of physics at the University of Illinois and appointed head of the physics department in 1957. He has since been appointed dean of the graduate college and vice president for research, University of Illinois, effective September 1, 1964. In 1962, he began a 4-year term as president of the National Academy of Sciences.

Dr. Seitz's major professional scientific interest has been in the theory of solids and nuclear physics. In addition to numerous review articles and scientific papers, he wrote "The Modern Theory of Solids" (1940) and "The Physics of Metals" (1943), published by McGraw-Hill. He is coeditor of "Preparation and Characteristics of Solid Luminescent Materials," published by John Wiley & Sons in 1948; coeditor of "Solid State Physics" series, Academic Press, Inc.; and author of the chapter on "Fundamental Aspects of Diffusion in Solids" in "Phase Transformations in Solids" (John Wiley & Sons, 1951). He is also a member of the editorial board of Il Nuovo Cimento.

He was a civilian member, National Defense Research Committee, 1941–45; consultant to the Secretary of War, 1945; director of the training program in atomic energy, Oak Ridge National Laboratory, 1946–47; and science adviser to the North Atlantic Treaty Organization, 1959–60. He is now a member, President's Science Advisory Committee; member President's Committee on the National Medal of Science; chairman, Defense Science Board; Department of Defense; member, Advisory Board to the Industrial College of the Armed Forces; member, Naval Research Advisory Committee (chairman, 1960–62), Office of Naval Research; member, Scientific Advisory Group, Office of Aerospace Research; member, Statutory Visiting Committee for the National Bureau of

Standards; consultant, Education Commission of Enquiry, Government of India; chairman, Science Advisory Council of Illinois; member, Policy Advisory Board, Argonne National Laboratory; member, Scientific Advisory Committees, United Aircraft Corp.; and of numerous other advisory and liaison groups.

Dr. Seitz is vice president of the International Union of Pure and Applied Physics; a member, Governing Board of the American Institute of Physics (chairman, 1954–59); member, Council of the American Physical Society (president, 1960–61); member, Board of the Midwestern Universities Research Association; member, Board of Trustees, Rockefeller Foundation; member, Board of Directors, Graduate Research Center of the Southwest; member, Board of Trustees, Education and World Affairs; member, Board of Trustees, Washington Center for Metropolitan Studies; member, Leopoldinian-Carolinian German Academy for Natural Sciences; and corersponding member, Gottingen Academy, Germany.

DR. JAMES A. SHANNON

Dr. James A. Shannon, Director of the National Institutes of Health, has devoted his professional career to medical research. After receiving his medical degree from New York University, he began his research career there and earned his Ph. D. in physiology. By 1940 he had become director of research at Goldwater Memorial Hospital, a medical division of the university.

Dr. Shannon has conducted original research in kidney function, chemotherapy, and malaria. During the war he played a prominent part in malaria research activities of the National Research Council and was a consultant on tropical diseases to the Secretary of War. In recognition of this work, he received the Presidential Medal for Merit, one of the highest awards for civilian service in the Government.

From 1946 to 1949 Dr. Shannon was directer of the Squibb Institute for Medical Research. He became associate director in charge of research for the National Heart Institute in 1949, and associate director of the National Institutes of Health in 1952. He has been Director of NIH since 1955.

In 1965 Dr. Shannon was elected a member of the National Academy of Sciences. Other awards have included the Rockefeller Public Service Award (1964), the Public Welfare Medal of the National Academy of Sciences (1962), and the Mendel Award from Villanova University (1961).

DR. CHALMERS W. SHERWIN

Dr. Chalmers W. Sherwin was born at Two Harbors, Minn., November 27, 1916. He has been an educator, research administrator, and Government official.

He was graduated in 1937 from Wheaton College, Ill., with a B.S., degree and received his Ph. D. in physics from the University of Chicago in 1940. He was an assistant in physics at the University of Chicago in 1941 and a member of the staff of the radiation laboratory of MIT from 1941 to 1945. He was in the physics department at Columbia University in 1946 before becoming assistant professor of physics at the University of Illinois, where he became an associate professor in 1948 and a professor in 1951. He has been with the Aerospace Corp., Los Angeles, Calif., since 1960.

During 1954–55 Dr. Sherwin, on leave of absence from the University of Illinois, served as chief scientist of the U.S. Air Force. Upon leaving that assignment he was awarded the Medal for Exceptional Civilian Service. He has also served various Government agencies as a consultant.

Dr. Sherwin is a fellow of the American Physical Society.

DR. RICHARD H. SULLIVAN

Dr. Richard H. Sullivan, president of Reed College in Portland, Oreg., graduated from Harvard College in 1939, magna cum laude. He received his master's degree in 1940 from the Harvard Graduate School of Arts and Sciences, and served as an assistant in English and chief proctor of dormitories the following year. He was appointed assistant dean of Harvard College in 1941. Following service as an intelligence officer in the U.S. Navy, Dr. Sullivan joined the College Entrance Examination Board in 1946, where he served as assistant director until 1948. He was appointed assistant treasurer of the Educational Testing Service in 1948, becoming executive vice president and treasurer the following year. Dr. Sullivan became president of Reed College in 1956. He was awarded the honorary degrees, doctor of laws by Pacific University in 1960, and doctor of humane letters by Hebrew Union College in 1961.

Dr. Sullivan is active in educational affairs on the national level. He is a member of the U.S. Office of Education's Advisory Committee for Graduate Facilities and the National Science Foundation's Divisional Committee for Scientific Personnel and Education. He is a trustee of the Committee for Economic Development. In 1955, under the sponsorship of the Carnegie Corp., Dr. Sullivan directed a special study which resulted in the formation of the Office of Statistical Information of the American Council on Education. He is a trustee of the College Retirement Equities Fund, elected by policyholders nationally; he has served as a trustee of the American Council on Education, the College Entrance Examination Board, and the Independent College Funds of America.

In Oregon, Dr. Sullivan has chaired a Governor's committee for the establishment of an Oregon Graduate Center for Study and Research. He is a member of the executive committee of the Metropolitan Interfaith Commission on Race and served on the Portland Public Schools' Committee on Race and Education. He has served as a member of the board of directors of the City Club of Portland.

DR. FREDERICK E. TERMAN

Terman, Frederick Emmons, educator, electronics engineer; b. English, Ind., June 7, 1900; s. Lewis Madison and Anna Belle (Minton) T.; A.B. in chemical engineering, Stanford University, 1920, E.E. 1922; Sc. D. in electrical engineering, Mass. Institute of Tech., 1924; Sc. D. (hon.) Harvard University, 1945; University of British Columbia, 1950; Syracuse University, 1955; married Sibyl Walcutt, March 22, 1928; children: Frederick Walcutt, Terence Christopher, Lewis Madison. Instructor to professor electrical engineering 1925–37, prof. and executive head electrical engineering department, 1937–45, dean School of Engineering 1945–58, Provost since 1955, Vice President since 1959, Acting President Feb.–Aug. 1964, Stanford University; dir. Harvard U. Radio Research Lab. (chief U.S. agency developing countermeasures against enemy radar), 1942–45; Mem. Divs. 14 and 15 Nat. Defense Research Com., 1942–45; Decorated by British Government 1946, awarded Medal for Merit, 1948; mem. Special Technical Advisory Group 1950–53, and TAPEC Committee 1953–56 of Dept. of Defense; mem. Signal Corps Research and Development Advisory Committee 1954–62; mem. Advisory Council Army Electronics Proving Ground 1954–57; mem. Naval Research Advisory Committee, 1956–64 (Chmn, 1957–58); mem. Defense Science Board 1957–58; mem. MPE Div. Committee of Nat. Sci. Fndn., 1955–59 (Chmn. 1958–59); Consultant Pres. Sci. Adv. Comm., 1959–; Board of Foreign Scholarships of State Dept. 1960–; Patent Panel, Dept. of Commerce 1963; director, Hewlett-Packard Company, Stanford Bank, Watkins-Johnson Co., Granger Associates; vice chairman, Stanford Research Institute; Trustee, Institute for Defense Analyses; Graduate Research Center of Southwest; SMU Foundation for Science and Engineering; mem. Nat. Acad. Sci. (Chairman Eng. Sec. 1953–56; Council, 1956–59); founding mem. Nat. Acad. Engrg; mem. Am. Philos. Soc; fellow Inst. of Radio Engrs. (director 1940–43, 1948–49, v.p. 1940, pres. 1941, Medal of Honor 1950; Founders Award 1962); Fellow, Am. Inst. of Elec. Engrs. (first recipient Education Medal, 1956), Am. Soc. Engring. Edn. (v.p. and Chairman of Administrative Council), 1949–51; dir. Research Council, 1948–51; Lamme Medal, 1964; Audio Engring. Soc. (hon. mem. 1955); Eta Kappa Nu ("Eminent Member", 1951), WEMA Medal of Achievement 1963. Bohemian Club. Author: Transmission Line Theory (with W. S. Franklin), 1927, Radio Engineering, 1932, 1937, 1947, revised as Electronic and Radio Engineering, 1955; Measurements in Radio Engineering, 1935; Fundamentals of Radio, 1938; Radio and Vacuum Tube Theory (in collaboration with U.S. Mil. Acad. staff), 1940; Radio Engineers' Handbook, 1943; Electronic Measurements (with J. M. Pettit), 1952; Contr. articles in tech. mags.; Consulting Editor, Electronic and Electrical Engineering Series, McGraw-Hill Book Co., Inc.; Home 659 Salvatierra Street, Stanford; Office: Provost's Office, Stanford University, Stanford, California.

DR. MERRIAM HARTWICK TRYTTEN

Born January 7, 1894, Albert Lea, Minn.

Education: 1916, B.A., Luther College, Decorah, Iowa ;1924, M.S., State University of Iowa : 1928, Ph. D., University of Pittsburgh.

Past experience: 1918–19, American Expeditionary Forces; 1917–24, instructor, phys, Luther College; 1920–21, American Scandinavian Foundation fellow, Oslo,

Norway; 1924–41, instructor, assistant professor, University of Pittsburgh; 1941–43, Office of Scientific Research and Development; 1943–44, War Manpower Commission; 1944—, Director, Office of Scientific Personnel, National Academy of Sciences-National Research Council.

Partial list of committees and advisory functions:

Chairman, Civil Service Commission Advisory Committee on Scientific Personnel, 1946–52;

Chairman, Selective Service Scientific Advisory Committee, 1949–52;

Member, Conference Board of Associated Research Councils, 1949—; chairman 1962–63;

Chairman, Committee on International Exchange of Persons (Fulbright program), 1950—;

Vice chairman, Commission on Human Resources and Advanced Training, 1950–54;

Member, Scientific Manpower Commission, 1959—; President 1961—;

Consultant, Engineering Manpower Commission, 1949—;

Consultant to several Federal agencies;

Fellow, American Physical Society.

Member: AAAS, ASEE, Cosmos Club.

Author, books and articles.

Honorary degrees: LL.D., Luther College, 1950; LL.D., St. Olaf College, 1951; D. Sc., Wesleyan College (Conn.), 1951; D. Sc., Carthage College, 1952; D. Sc., Drexel Institute of Technology, 1956; D. Sc., University of Pittsburgh, 1962.

DR. ERIC A. WALKER

Eric A. Walker was born in Long Eaton, England, April 29, 1910, and came to this country as a young boy. He received his bachelor's, master's and doctor of science degrees from Harvard, and holds honorary doctorates from many universities.

As an engineer, he has made significant contributions in the fields of acoustic properties of liquids, high-voltage insulation, and electromagnetic precipitation. During World War II, he helped develop the acoustic homing torpedo, which was instrumental in breaking the submarine blockade. For this and other war research, he won the Naval Ordnance Development Award and the Presidential Certificate of Merit.

He headed the department of electrical engineering at Tufts College, at the University of Connecticut, and at the Pennsylvania State University, where he also directed the Ordnance Research Laboratory. At Penn State he was later dean of the College of Engineering and Architecture, and since 1956 has been president of the university. He has been a member of the Board of Visitors of both the U.S. Naval Academy and the U.S. Military Academy. He was a founder of the National Conference on the Administration of Research, and has held leading positions in many educational associations and commissions at both State and National levels. He has been president of the American Association for Engineering Education, and of the Engineers' Joint Council.

He was a member of the Army Scientific Advisory Panel, Vice Chairman of the President's Committee for Scientists and Engineers, and Chairman of the National Research Council's Committee on Undersea Warfare. He is currently Chairman of the Naval Research Advisory Committee, Chairman of the Board of the National Science Foundation, and a member of the Defense Science Board. He is vice president of the National Academy of Engineering, having been one of the prime movers in its establishment.

Dr. Walker's accomplishments have been widely recognized by many awards and other honors, including the Horatio Alger Award, the American Legion Distinguished Service Medal, and the Tasker E. Bliss Award of the American Society of Military Engineers. He serves as board member of a number of organizations, and is consultant to various industrial companies.

DR. ALVIN M. WEINBERG

Alvin Martin Weinberg, physicist, was born April 20, 1915, in Chicago, Illinois. He holds the A.B. (1935), the A.M. (1936) and the Ph. D. (1939) from the University of Chicago. He was a member of the President's Science Advisory Committee, 1960–62. Dr. Weinberg received the Atoms for Peace Award (1960). He is a member of the American Nuclear Society and the National Academy of Sciences. He is Director, Oak Ridge National Laboratory.

DR. DAEL WOLFLE

Dael Wolfle is executive officer of the American Association for the Advancement of Science, the large, national, membership society that represents all fields of science. He received the bachelor of science and master of arts degrees from the University of Washington, in Seattle, and, in 1931, the doctor of philosophy degree from the Ohio State University.

Prior to World War II he served on the faculties of the Ohio State University, the University of Mississippi, and the University of Chicago. During World War II he was Civilian Training Administrator with the Army Signal Corps and a technical aide in the Office of Scientific Research and Development.

From 1950 to 1954 he was Director of the Commission of Human Resources and Advanced Training. This Commission was established by the National Academy of Sciences and the research councils in education, social science, and the humanities to study the Nation's resources, potential resources, and supply of persons in science, engineering, and the other professions. It made extensive use of data from the Bureau of the Census, the Bureau of Labor Statistics, and the national rosters, and conducted its own special studies of specialized manpower supply and demand.

He is a member of the National Advisory Health Council, the Commission on Graduate Medical Education, and advisory committees to the National Science Foundation; chairman of the Commission on Human Resources and Advanced Education; and a former member of the Defense Science Board of the Department of Defense, of the Scientific Advisory Board of the Air Force, and of advisory bodies to the Office of Naval Research, the Civil Service Commission, the Department of Labor, and other national and international governmental organizations.

CONTENTS

VOLUME II

APPENDIX 1

Summary of Testimony

June 23, 1965

Witness: Dr. Leland J. Haworth, Director, National Science Foundation.

A. Highlights of statement

1. Issue of NSF and Government participation in basic research raised in Academy report and LRS report relate to problems pointed out in last NSF annual report.

2. Increase in Federal funding for R. & D. from $1 billion with $50 million for basic research in fiscal year 1950 to $15 billion and $1.9 billion in fiscal year 1965 has resulted in (*a*) increased tempo in science and (*b*) qualitative improvement of scientific effort.

3. Three objectives of Federal research support: (*a*) to assure maximum scientific and technological preeminence; (*b*) to develop means required for national programs, such as military defense and space, and (*c*) to contribute to benefit of the people.

4. NSF mission: "the advancement of science in the national interest" through "supporting the extension of scientific knowledge and the strengthening of the educational processes leading to such extension."

5. NSF growth and development:

a. Act of 1950 made NSF responsible for promotion of basic research and education in the sciences, and for pursuit of national science policy.

b. Roles of Director and NSB delineated; delegation discussed.

c. Growth of activities:

(1) Early pattern for support of research in universities established by ONR, NIH, AEC, and others prior to NSF.

(2) Early attention to statistical studies and analyses of national R. & D. and questions related to scientific and engineering manpower.

(3) Review by panels by peers.

(4) Project method, "still the Foundation's major means of supporting research."

(5) Graduate fellowships.

(6) Later programs—national research programs, support of research facilities, establishment and support of national research centers, new mechanisms in science education.

d. NSF emphasizes "investment in people as a broad element of the strategic approach to helping science move forward." Discussion of—

(1) Research support to encourage growth in academic research activities;

(2) Increasing research in areas of national interest;
(3) Upgrading quality of science education;
(4) Attracting students to science; and
(5) Stimulating growth of existing and new centers of excellence.

e. Science education:
(1) NSF interested in improvement at all levels.
(2) Programs have three objectives:
(a) Providing advanced training;
(b) Improving quality of course materials and teaching methods; and
(c) Improving science teachers.
(3) " * * * concern in science education is directed primarily at the qualitative aspects" aiming to produce better students and teachers.
(4) NSF a "trail breaker" in experiments to improve learning.

f. Direct funding of academic institutions for (1) graduate laboratories; (2) institutional base grants; and (3) science development grants.

g. Science information program goes beyond basic research. Does not involve large expenditures, but impact is broad. Translation and dissemination of foreign science information, and development, funded by NIH, DOD, and NSF, of high-speed source of chemical information for scientists—a pioneering effort in government interagency coordination in information systems field.

h. Science resources planning:
(1) More than 95 percent of NSF appropriations devoted to support of science and science education; remainder to science resources planning.
(2) Reorganization Plan No. 2:
(a) Director, OST, given NSF's former policy function concerning advising and assisting the President in achieving "coordinated Federal policies for the promotion of basic research and education."
(b) NSF continues to originate policy proposals and recommendations concerning support of basic research and education in sciences, and provides OST with studies and information on which to base national policies in science and technology.
(c) Factfinding and analysis function expanded to perform latter assignment, and resources planning given greatly enhance organizational position. "Now that we have gathered and have at hand a more nearly adequate base of information, we believe we can launch a major effort to isolate particular road blocks and problems in the path of the Nation's scientific development—and thus assist more effectively in the development of policies to assure healthy scientific progress for the country."

*B. Highlights of charts and tables** (*Nos. 1–11*)

1. "Purposes of the Federal Science Complex" (chart 2)—Shows interrelationship between parts of complex.

2. "Executive Branch Science Coordination" (chart 3)—Elementary relationships within the executive branch. "* * * fair to say that OST, Dr. Hornig and his office, look unusually strongly to the NSF for assistance in helping them develop information and policy both for OST and for the Federal Council * * *."

3. "National Science Foundation Activities in support of Science and Science Policy Development" (chart 1)—Schematic of NSF activities.

4. "Funds Used for Research, Development, and R. & D. Plant, by Source of Funds, 1963" (chart 4)—Calendar year 1963 data for Government and non-Government activities. Federal support for development exceeded total research support.

5. "Research and Development, 1963" (chart 5)—Shows source and use of funds. R. & D. plant is not included. Federal Government provided about 65 percent of total spent on R. & D. About a quarter of funds for academic research provided by universities, including public and private support.

6. "Trends in Federal Obligations for Basic and Applied Research, Development and R. & D. Plant" (chart 6)—Shows some of trends in Federal R. & D. from fiscal year 1956 to fiscal year 1965.

7. "Basic Research, 1963" (chart 7)—of $1.8 billion, 58 percent provided by Federal Government, 22 percent by industry, 12 percent by colleges and universities, and 8 percent from private foundations. Data may be distorted by differences in definition of basic research in academic institutions and in industry.

8. "Trends in Federal Obligations for Basic Research, by Field of Science" (chart 8)—Shows trend of Federal support of science and trend of support of various fields.

9. "National Science Foundation as a Source of Funds" (chart 9)—In 1964 NSF provided about 1 percent of all A. & D. funds in country; about 12 percent of all R. & D. at colleges and universities, but roughly 10 percent of all Federal basic research.

10. "Mechanisms of Support" (chart 10)—Shows how NSF programs may serve more than one function. All institutional programs affect both research and science education. Science information has indirect effect.

11. "Distribution of Funds for Direct Support of Science" (chart 11)—Shows where money goes—to colleges and universities, nonprofit organizations, individuals, industry, other Government agencies.

C. Highlights of questioning

1. Geographic distribution of fellowships directed by enabling legislation; applicants ranked in quality groups; selection for geographic distribution at lower levels; no detriment to merit principle of selection because choosing from "substantially equal ability."

2. Proposed limitation on fellowships according to residence would be barrier to selection on merit; and would penalize students for residence rather than ability.

*Charts referred to by Dr. Haworth can be found in vol. I, pp. 13–30.

3. NSF may pick up slack as mission agencies reduce their basic research.

4. R. & D. figures for industry not distorted by charging R. & D. to production. Notes fuzzy definitions of R. & D. in data gathering. Believe industrial data "accurate within a spread of several percentage points."

5. On statistics: "None of these numbers should be taken too literally except the numbers that represent how many checks the U.S. Government did write for something."

6. Science students can obtain support to become teachers through competitive fellowships program—not through education programs for existing science teachers. Preservice teacher training is being discussed; some small experimental programs at present.

7. Re U.S. support of foreign science: "I personally feel that cooperation in science offers one of the few windows that show any real promise of solving some of our really important problems of the world."

June 24, 1965

Witness: Dr. Leland J. Haworth, Director, National Science Foundation.

A. Continuation of discussion of charts

1. "Science Programs Support, fiscal year 1965" (chart-table 12) which comprise about 75 percent to operational funds, 16 percent for facilities.
2. "Table—Science Programs Support" (chart 12–A)—Breaks down NSF research and education totals in detail.
3. "Total Research Program Funds, by Research Areas" (chart 13)—Relative NSF support of research in different fields. Most funds go to mathematical and physical sciences; social science support has highest growth rate, with engineering close behind.
4. "Distribution of Basic Research Project Grant Funds by Type of Expenditure" (chart 14)—Shows representative use of funds for basic research; salary shown separately.
5. "Science Education Programs Support, Fiscal Year 1965" (chart 15)—NSF's science education programs. Course content improvement materials. Noted:

    O. of E.-NSF relations need for careful delineation of functions;

    Existence of "quite close knowledge and cooperation";

    Belief that graduate science education is predominant NSF responsibility;

    At other levels, especially in high school and elementary schools, NSF should be a leader and innovator.
6. "Funds Directed Primarily Toward Support of Science Education" (chart 16)—Step up between 1963 and 1964 due to initiation of traineeship program as result of PSAC recommendations.

B. Highlights of questioning

1. Social science support began with social psychology and gradually expanded to other fields.
2. Establishment of Humanities Foundation welcome. Might be a "fuzzy edge" for social sciences. Humanities Foundation badly needed—would be complementary to rather than competitive with NSF.
3. No fixed proportion of NSF budget for social sciences.
4. Larger representation of physical sciences on NSB, but social sciences "well represented."
5. Re allocation of funds between different fields, criteria are "rather general and vague"—one important criteria is simply what is the situation with respect to good research that is being proposed.
6. Criteria for evaluation: Proven ability of researcher, value and potential productivity of ideas, and proposed course of action.
7. Funds insufficient to support all good research proposed.
8. NSF charter extends only to basic research in engineering.
9. Delineating O. of E. and NSF responsibilities "will require great care." Sensible guidelines from Congress may be helpful.

June 25, 1965

Witness: Dr. Leland J. Haworth, Director, National Science Foundation.

A. Continuation of discussion of charts

1. "Funds Directed Primarily Toward Support of Science Education" (chart 16)—Effect of support at precollege, undergraduate, or graduate level shown.

2. "Support of Individuals Under Selected Science Education Programs" (chart 17)—Since many took part in more than one program, data does not represent total of individuals participating.

3. "Total Fellowship and Traineeship Awards, Fiscal Years 1952–56" (chart 18)—Adverse effect on quality of proposed percentage limitation on fellowship awards by States of residence discussed. Individual or economic need not factors in selection. Breakdown of NSF predoctoral fellowship and traineeship awards, by program and field, Fiscal Year 1965, submitted for record; list of institutions granting Ph. D.'s to be supplied.

4. "Universities and Colleges Receiving NSF Funds in Support of Science, Fiscal Year 1964" (chart 19)—Note, many institutions receive grants in more than one category.

5. "Support Funds Compared With Degrees Awarded and High School Graduations, by Geographic Division" (chart 20)—Distribution of NSF research funds, excluding facilities, among nine geographic divisions. Mentions numbers of doctoral degrees, of other degrees, and of oncoming students as indicators. State financing in central United States appeared higher than for East. Not certain about comparison with west coast. Five of ten universities that get most Federal support are in north-central region: Chicago, Ill., Wisconsin, Minnesota, and Michigan.

6. "Fellowship Awardees, Fiscal Year 1965, Compared With Two Educational Characteristics, by Geographic Division" (chart 21)—Distribution seen as relatively even.

7. "Total Personnel and Scientific Professional Personnel, 1959–65" (chart 22)—What is spent inside NSF for administration. Ratio of operating costs to total obligations has declined slightly.

8. "Projection of Federal Obligations for Basic Research in Universities and Colleges Proper, Fiscal Years 1966–75" (chart 23)—Federal basic research at universities almost $2½ billion by 1975. Present Federal basic research represents half of total Federal R. & D. support to colleges and universities.

9. "Projection of NSF Obligations for Basic Research in Universities and Colleges Proper, Fiscal Years 1966–75" (chart 24)—If NSF

maintained a constant 15 percent of Federal total basic research support, support would grow from $130 million to a little under $540 million.

B. Highlights of statement[1]

1. Increased role for NSF in basic research:

a. Assumes support of basic research in mission agencies to continue.

b. NSF the logical agency to fund major fraction of new and expanding requirements.

c. General agreement in executive branch, in Congress and in scientific community that Federal Government must continue major support of academic research, and provide for appropriate growth.

d. Increased support necessary because (1) many first-rate scientists not now adequately supported; (2) as enrollments expand, increased faculty and graduate students will need support, estimated 8 to 10 percent annual increase, and (3) costs of more sophisticated equipment and additional supporting personnel constantly rising, 5 to 7 percent.

e. Overall increase of 15 percent or more in support of research in academic institutions needed "to hold our own." Matter is under study by a panel of PSAC; NSF providing major support of staff for project.

f. NSF share of basic research calculated for fiscal year 1966 on basis of 15 percent increase, plus shortfall in other agencies estimated at $50 to $55 million.

g. Continuation, strengthening and expansion of national research centers necessary. Project Mohole expected to become a national research center. Centers necessary to advancement of science and to supplement university resources.

2. Nature of NSF support at academic institutions:

a. How to strengthen individual centers of higher education:

(1) Methods of research support:

(a) Project support best, despite disadvantages.

(b) "Judgment by peers" considered best means to evaluate proposals.

(c) Institutional base grants intended to offset disadvantages of project system—(1) lack of flexibility and (2) decreased freedom of action of academic administrators.

(d) NSF planning to broaden base for institutional grants to include total Federal funds to an institution.

(e) Planning more comprehensive research project grants to support groups of individuals from more than one field.

(f) Notes tendency of project system to concentrate research support in a few institutions.

---

[1] Dated June 24, 1965: NSF in the Federal science structure of the near and low-range future.

b. How to help build stronger institutions of higher education throughout the country:

(1) Maintain and improve existing centers of excellence.

(2) Assist graduate institutions of recognized ability to develop their potential; build up "pockets of strength" in educational institutions.

(3) Assist younger scientific and engineering faculty members from smaller institutions.

(4) Lift general quality of undergraduate science education.

These courses of action adopted by FCST as guidelines for future. First three apply to all Federal agencies, fourth to NSF alone. Courses of action intended to meet different needs and require different criteria in implementation. Must continue to stress quality and at same time work to develop future ability.

Need to develop simpler and less constraining support of university and college research.

c. Science education:

(1) Need to upgrade quality at all levels and in all fields.

(2) Assure future science teachers are well prepared.

(3) Continue emphasis on science instruction at precollege levels.

(4) Maintain and strengthen ties with O. of E. and all other groups, private and public, supporting programs in science education.

d. NSF leadership called for in—

(1) Promotion of basic research.

(2) Weather modification and science information.

(3) Interdisciplinary problems.

(4) NSF to more fully utilize legislative authorization in ways beneficial to Nation.

B. Highlights of questioning

1. NSF predoctoral fellows originally full time on study and research: first allowed to teach in 1955; since academic year 1961–62, university allowed to pay up to $1,000 for teaching. At last count about one-third of fellowship holders from regular and cooperative graduate programs were teaching; believe proportion of traineeship grant holders would be comparable.

2. Maximum teaching allowance by institution originally set at $600; increased to $1,000 in 1964–65 fellowship year. Present figure believed appropriate.

3. Immigration of Ph. D.'s from north-central region to both coasts is result of (1) location of industrial R. & D. and (2) location of in-house Government R. & D. Believes immigration not as common now as formerly.

4. No objective yardstick exists to determine relative quality of various institutions at college educational levels below Ph. D.

5. Does not believe geographic distribution factors of less concern to NSF than formerly, or that NSF distribution of support is more concentrated at present.

6. On criticism that charts do not relate actual distribution of total population to other factors, a counter question was raised about NSF responsibility to strengthen education throughout the country, and use of its funds where some strength already exists. Thought the two objectives should be kept somewhat separate. Initiative and cooperation at grassroots needed.

7. Guideline for giving geographical preference not same for fellowships and research.

June 29, 1965

Witness: Dr. Donald F. Hornig, Director, Office of Science and Technology, Executive Office of the President.

A. *Highlights of statement*

1. Relationships between OST–NSF:

a. Noted difficulties inherent in original legislation that gave NSF overall policymaking and evaluation function, and changes made through reorganization since 1957 to focus policy formulation and central coordination in the Executive Office of the President.

b. Explanation of increased NSF budget—

Fifteen percent increase in total national program in basic research in universities figured on (1) plans of agencies for support of academic research, (2) projected growth of student enrollments, (3) increased costs of education and research. Because much support of basic research in universities comes from the NSF, nearly 50 percent proposed increase for this purpose.

Failure to obtain requested amount will result in declining support for university science students.

c. Present NSF participation in policymaking process consists of—

(1) Making policy recommendations and acting to enhance health of American science.

(2) Organizing and carrying out interagency studies and evaluations when requested by OST.

d. OST–NSF relationships:

(1) Relationships dependent on unique functions and capabilities of NSF:

(a) NSF as collector and analyzer of basic data on science resources and on nature of Federal R. & D. expenditures which OST uses for national science policies.

(b) NSF as executive agent or delegated agent of OST in exercising leadership on programs of broad importance, as for example, in developing interagency assessment of and reaction to NAS report on ground-based astronomy.

(c) NSF as a source of advice to OST on national science policies.

(d) NSF, supported by OST, has increasingly "taken into consideration" extent and character of other Federal agencies in support of academic research, as for example, intent of Foundation next year to use total Federal Government expenditures as base for institutional grant program.

(2) Relationships of NSF with other Federal R. & D. agencies:

(a) OST and PSAC review NSF programs as they do programs of other agencies.

(b) NSF is a full member of FCST and may provide staff for assistance on panels of FCST.

2. Major questions regarding future overall program of NSF:

a. Increase of NSF support of scientific activities directed at particular national goals.

b. Increased NSF attention to applied research presently not the responsibility of research of mission-oriented agencies; e.g., improvement of national systems for dissemination of scientific and technical information, and increased attention to education and academic research in engineering.

B. Highlights of questioning

1. One of the purposes of establishing OST was to provide more effective communication with Congress through appearances at Congressional hearings and through published reports; a report of FCST is now in process.

2. Method of operation of FCST is to coordinate agency activities in particular fields such that the exact location of a particular activity is subordinated to ready availability of end product.

3. Wooldridge report cited as example of evaluation of scientific research programs since this responsibility was transferred to it from NSF. Recommendations translated into action through (1) consultations, (2) submission of legislative programs, and (3) recommendations concerning agency budgets.

4. OST limited in evaluating role by size of staff. Sees committee method excellent for collecting information; but not to provide leadership.

5. OST summer study by a PSAC panel under Dr. Harvey Brooks will seek some rational guidelines for academic research and for its growth, choice among fields to support and coordination of efforts by many agencies. Will consider specifically (*a*) criteria for distribution of funds for research at universities to strengthen and increase number of first-rate institutions and to broaden the base of scientific research and education; (*b*) ways to broaden geographic distribution of support to universities; (*c*) balance between project support and increased institutional responsibility for larger program elements, and (*d*) role of postdoctoral students.

June 30, 1965

Witness: Dr. Frederick Seitz, President, National Academy of Sciences.

A. Highlights of statement

Discussed (1) importance of NSF to science in United States, (2) NSF–NAS relationships, and (3) NSF foreign activities.

1. National importance of NSF:

a. Creation of NSF recognized importance of basic science to the Nation.

b. In developing programs and budget, NSF administrators draw on advice from a large part of the scientific community. In dividing funds between NSF programs, congressional committees should seek advice of the "scientific community."

2. NSF–NAS relationships:

a. Scientists who proposed NSF were for most part closely associated with NAS.

b. President of NAS, Dr. Bronk, also chaired National Science Board for years.

c. Examples of NAS–NSF cooperation: (1) IGY; (2) Committee on Science and Public Policy—major support from NSF; (3) Project Mohole; (4) Office of Critical Tables; (5) Automatic language processing; (6) Scientific personnel—NAS evaluates NSF fellowship applications; (7) continuing study of special fields through special committees; as e.g., Committee on Polar Research, Committee on Atmospheric Sciences, etc.

3. NSF–NAS foreign activities:

a. Support of international scientific conferences and programs, such as IGY, international biological program, and International Indian Ocean Expedition.

b. Management of international scientific activity, through NSF–NAS support of U.S. national committees of international scientific unions, Scientific Committee on Antarctic Research, and Scientific Committee on Oceanic Research.

c. Scientific exchange activities with Academies of U.S.S.R. and of eastern European nations.

B. Highlights of questioning

1. No strong opinion whether NAS and NSF are too close to permit objectivity. During NSF's growth, close NAS ties were valuable. Working relations at present excellent. Sees no conflict of interest in concurrent NAS–NSF memberships "so long as issues discussed were general policy matters."

2. Would like to see scientific community consulted when adjustments are made in the NSF budget. Possible at this time by consulting the Academy, but Academy only one spokesman for the scientific community.

3. Against NSF involvement in any massive way in applied science activities.

4. Mission-oriented agencies must support basic research related to their missions.

5. Greatest concern is that pressure for support of very large programs will result in individual scientist not being adequately funded.

6. Considered 1966 NSF budget very well balanced.

7. NSF draws advice from the scientific community through its Science Board, various advisory panels, from PSAC, OST.

8. Believes private and State sources of basic research support are definitely growing in proportion to the Federal funding.

9. No simple solution to difficulties of small schools in attracting good researchers. Partial solution is for small school to establish relationships with bigger universities wherever possible, for use of facilities.

10. Would like to see a half-and-half allocation of funds between project grant support and institutional grant support.

Witness: Dr. Alan T. Waterman, former Director, National Science Foundation.

A. Highlights of statement

1. Breadth and flexibility of National Science Foundation Act of 1950 a tribute to Congress:

a. Misunderstandings concerning the act, which were later clarified:

(1) Initial decision that NSF should not support all of basic research. Decision confirmed by Executive Order 10521 of March 1954.

(2) Initial decision that NSF should not evaluate the the research programs of other Federal agencies. Evaluation functions in act interpreted to be evaluation of science programs, not agency programs. Agency programs should be evaluated at a higher level.

(3) Coordination of Federal agencies a responsibility of FCST and OST rather than NSF.

2. Suggestions concerning future of NSF:

a. NSF proportion of Federal support in basic research to academic institutions, presently less than 30 percent, should be markedly increased ["to at least 50 percent"].

b. NSF should lead overall consideration of basic research subject matter areas and should continue to develop the programs of its Office of Science Information Service.

c. Increased reliance on National Science Board.

d. Increased responsibility for support of education and training in science and engineering, in close cooperation with O. of E.

e. Continued cooperation with nongovermental scientific organizations.

f. Funds to provide (*a*) continuity of support, and (*b*) contingency funds.

g. Increased international cooperation.

3. Questions involving technology must be decided by society; they cannot be left to scientists and engineers alone.

B. Highlights of questioning

1. Motivations of mission-oriented agencies for engaging in basic research should be requested from agencies themselves. If matter becomes acute, would be a matter for study by OST.

2. No external guidelines exist concerning what basic research particular agencies may support. Individual agencies would have to be queried regarding internal guidelines.

3. Evaluation role of OST must be by categories of projects; panels to deal with matters within a category. Agencies must be made more aware of their review responsibilities. Suggested periodic overall reviews supplemented by closer agency communication and perhaps some delegation of authority from OST.

4. Science education should not in general be spread around among various agencies. Mission-oriented agencies should deal only in education at graduate level and only in specific areas in furtherance of mission. Activities should be coordinated with NSF.

5. Increased use of National Science Board suggested with respect to national policy for science and in educational institutions; could be useful to OST.

July 1, 1965

Witness: Dr. Dael Wolfle, Executive Director, American Association for the Advancement of Science.

A. Highlights of statement: The statistical functions of the NSF

1. Available NSF statistical information inadequate: wants more, in greater detail, more promptly:
2. Reasons for dissatisfaction with NSF statistical data:
   a. Questions can always outrun available information.
   b. Not feasible to collect all information that someone might want.
   c. Inherent limitations of future trends and projections.
   d. Inevitable delays in collection, processing, and publishing information.
3. NSF problems in data collection:
   a. As "focal agency" NSF has no "police power"; can only coordinate agency activities by persuasion and voluntary agreement.
   b. Low priority by NSF, Bureau of Budget, or by Congress.
4. Wolfle's recommendations:
   a. Assign a higher priority, and support, or stop complaining.
   b. Use better data-processing equipment.
   c. Collect manpower "flow" information in addition to information on current status.
   d. Establish a special agency to interpret, synthesize, criticize, and improve methodology of scientific manpower studies.

B. Highlights of questioning

1. If removed from data-gathering and reporting activities, proposed new agency could be established within NSF; function more important than organizational arrangement.
2. As stated in "Science" editorial, believes NSF role should remain in pure sciences, with applied science continuing to be the responsibility of mission-oriented agencies.
3. Shifts in fields or places of employment are related to (1) amount of training received in a field, (2) caliber of individuals involved. Fluctuations in budget support have not resulted in adversely affecting large numbers of persons.
4. While not familiar in detail with data-processing equipment of NSF, understand both NSF and O. of E. are studying their own needs and what newer and better equipment would aid them.
5. Does not believe interest in basic research has resulted in neglect of applied science or loss of leadership; problem rather one of balance or application: perhaps greater attention should be directed to gaps in applied activities, chiefly in nondefense, nonspace applications.

6. NSF stimulation of basic research has been beneficial overall despite resultant diversion from applied science.

7. NSF does not need additional legislative authority to devote more effort to manpower studies; principal need is allocation of more money to this activity; an increase in present allocation of 1½ percent of current budget to 2–4 percent would result in improved situation.

8. As Federal role in education increases, responsibility will have to be divided, either by (1) field of interest or discipline, or (2) between levels of educations. Suggestion in "Science" editorial referred to possibility of an organizational unit which would focus on maintenance of scholarship and education and research at the higher levels, and in all fields.

Witness: Dr. Chalmers W. Sherwin, Deputy Director, Defense Research and Engineering (Research and Technology), Department of Defense, appearing for Dr. Harold Brown, Director, Defense Research and Engineering, Department of Defense.

A. Highlights of prepared statement

1. Interaction between DOD and NSF—aspects of—
   a. At OST–FCST policy level.
   b. Interagency major program planning; for example—
      (1) Antarctic research program.
      (2) International Years of the Quiet Sun.
      (3) International Indian Ocean Expedition.
   c. Coordination on "small projects":
      (1) Problems—
         (a) Cannot be sure right agency is supporting right project.
         (b) Do not know of research proposals which never were accepted and sponsored.
   d. Mutual support of specific projects; for example—
      (1) Stratoscope II: NSF, DOD, NASA.
      (2) Joint radio-astronomy project at Cal-Tech.
   e. Exchange of information on composition of research programs:
      (1) Project ILSE.

B. Highlights of questioning

1. A centralized research agency which has coordinating authority on projects would result in a very cumbersome decision procedure. Preferable to provide for accurate reporting system.

2. DOD providing no direct support for science education. Supporting about $130 million to universities for research programs related to the educational process.

3. DOD giving no fellowships or individual aid.

4. Conclusions from project "Where Do Good Ideas Start?": Most of key advances came from designers and builders of systems equipment, locally financed.

5. No established guidelines in DOD for project acceptance or referral; believed unnecessary.

6. Organized procedure for evaluation by peers applies only to one-quarter of DOD support of research in universities; three-quarters of $400 million total support to universities for contract centers and applied research programs.

7. Public availability of materials from Project ILSE a possibility.

8. Determination of R portion of R. & D. contract very hard to estimate.

9. No DOD policy re geographical distribution of contracts.

10. No clearly established policy in Department of Defense on possibility of making geographic distribution a basis for selection when other aspects of contract selection not clearcut.

11. DOD has no mathematical analysis to predict long-range manpower needs; has studies, analyses, and plans, but they are without mathematical tools.

12. DOD uses NSF's scientific and engineering manpower information to the degree they are related; would like to see improvement in data; DOD would like followup information on persons it previously supported.

July 6, 1965

Witness: Dr. Glenn T. Seaborg, Chairman, Atomic Energy Commission.

A. Highlights of statement

1. NSF and mission-oriented agencies should continue vigorous support of basic research.

2. AEC–NSF relationships:

a. Means of coordinating scientific planning and programs:

(1) Physical research:

(a) Formal interagency committees established under FCST—

(i) Technical Committee for High Energy Physics.

(ii) Coordinating Committee for Materials Research and Development.

(b) Solid State Sciences Panel of NRC of NAS and liaison representatives to Division of Physical Sciences and Division of Chemistry and Chemical Technology of NAS–NRC.

(c) Informal interagency groups (about eight) concerned with program coordination.

(d) Exchanges of lists of proposals.

(e) Telephone contacts.

(2) Multiple agency support to individual scientists especially in chemistry and materials sciences. NSF has collected data from Federal agencies to reduce multiple support in certain fields of science.

(3) Basic nuclear engineering research considered neither basic nor applied research by AEC or NSF. Unsuccessful attempts made by AEC in fiscal years 1964 and 1965 to obtain funds for a separate category of "Basic nuclear engineering"; proposals still being handled within existing programs, as in the past. In role as "balance wheel" NSF could request increased funds for this activity.

(4) Biomedical research relationships vary according to field—e.g. systematic biology is responsibility of NSF; molecular biology, genetics, developmental biology and metabolic studies draw joint NSF–AEC support; in life sciences, AEC deals with NIH. Both AEC and NSF are represented on interagency committees.

b. Education and training activities:

(1) Major emphasis of AEC program is to provide equipment for training graduate students; training undergraduates is secondary; NSF provides equipment grants "for all

fields of science and solely for undergraduate teaching." NSF supplies equipment for general science programs while AEC concentrates on nuclear-science programs. Neither AEC nor NSF has sufficient funds to meet all educational needs.

(2) AEC policy regarding fellowships restricts granting to those whose stated intent is to prepare for careers in atomic energy.

(3) AEC recently instituted a traineeship program, similar to that of NSF which directs funds to specific institutions.

(4) Coordination through meetings of Federal fellowship administrators and re AEC–NSF specifically, through continuous informal exchange of data, plans and problems.

(5) AEC administers two types of faculty institute programs: (1) Short topical conferences for undergraduate and graduate faculty of engineering institutions, funded by AEC through ASEE, and (2) AEC–NSF faculty institutes and conferences for college and high school faculty in specialized topics.

(6) Support of nuclear reactors at universities. Since 1956 by informal agreement, NSF supports university research reactor construction, AEC support specialized training reactors. Neither agency providing level of support recommended by NAS–NRC panel reporting in October 1964.

c. Other more limited interactions AEC–NSF: providing data on R. & D. funding levels, getting NSF assistance on manpower surveys, in technical information area.

3. Future role of NSF:

a. NSF must support areas of research not now receiving adequate attention from mission-oriented agencies.

b. NSF must provide for additional educational opportunities for high school, undergraduate, graduate students and faculty in sciences.

c. Need additional funds—

(1) To support highest quality research.

(2) To support research at less well-known institutions.

(3) To expand science development grants and institutional base grants programs.

d. Additional efforts in curriculum development.

B. Highlights of questioning

1. AEC has had no jurisdictional disputes with NSF that have had to be referred to higher level for settling.

2. Informal day-to-day telephonic contact the most important coordinating device.

3. International scientific activities of AEC include—

a. Support of research abroad.

b. Exchange of information on peaceful uses of atomic energy.

c. Publication of nuclear science abstracts.

d. Support for attendance of scientists at international meetings.

4. Policy on support of research abroad—when it can be done better there than anywhere else.

5. AEC at present at a "sort of crossroads in our controlled fusion program;" panel under Professor Ellison of University of Chicago is expected to report by end of year; may then recommend different directions or possibly an expansion of program.

6. Problems of obtaining large amounts of energy from the fusion reaction not expected to be solved before end of century; more money might shorten time somewhat.

7. Shifting between fields of persons trained in nuclear physics no cause for concern.

8. AEC's research in universities quite widespread. Since isolation was a factor in location of national laboratories, result has been good spread also into remote areas.

9. Supported 15 percent increase per year to continue present level of academic support.

July 7, 1965

Witness: Dr. Hugh Dryden, Deputy Administrator, National Aeronautics and Space Administration, accompanied by Dr. Homer E. Newell, Associate Administrator.

A. Highlights of statement

1. Plurality of Federal research support has been accepted and endorsed by Federal Government and by academic community. Problem is how to coordinate the total Federal research activity in the national interest.

2. NASA–NSF interrelationships—aspects of—

a. Support of basic research.

b. Graduate training.

Coordinating through (1) meetings with heads of agencies and Federal fellowship administrators—an ad hoc interagency group; (2) Federal Interagency Committee on Education; and (3) daily contacts between staff.

3. Suggestions for future role of NSF:

a. NSF must take lead in developing of a broad base of scientific activity in all parts of the Nation, while mission-oriented agencies must continue to give prime consideration to competence.

b. NSF might extend its activity to research and training at undergraduate level, at present receiving too little Federal attention.

B. Highlights of questioning

1. Recommendation for increased education support to undergraduate students not exclusively directed to NSF; NASA has also considered; institutional aid suggested rather than more direct aid to individual undergraduates.

2. Mission-oriented agencies must give prime consideration to competence when selecting proposals for applied R. & H.; not so critical for basic research.

3. NASA sponsors few social science projects; agrees that NSF's responsibility should include social sciences and engineering.

4. NASA and NSF coordination: Information on proposals and actions exchanged; periodic lists assembled; frequent telephone and personal contacts. NASA also cooperates with SIE. OST coordination noted.

5. NASA program managers are responsible for getting their jobs done. They solicit and receive proposals for R. & D. and decide whether work should be obtained from colleges and universities or industry, or from NASA centers. NASA also has a more general program for university research which receives unsolicited proposals.

6. Decision for NASA to support production of 1,000 Ph. D.'s annually was an executive branch decision extending from PSAC: part of a concerted agencywide effort to increase number of Ph. D.'s by 4,000 a year; doubts NASA would continue at same rate indefinitely.

Witness: Dr. Don K. Price, Dean, Graduate School of Public Administration, Harvard University.

A. Highlights of statement

1. Price considered role of NSF, in relation to other Federal agencies including—

   a. Executive branch development of its science policies, and

   b. Relation of applied and basic research throughout the Government.

2. NSF is a "most successful political invention."

3. Main issues debated during establishment of NSF were relation of science to political authority and relation of basic science to applied science. Noted that the former was the more fundamental problem, but the latter has caused more difficulty.

4. Science and political authority:

   a. Broader and more practical support of science by Government raised fears of science being supported for its social utility and being directed by political authority—not advocated by Bush report which stressed basic research in independent institutions. Fears proven groundless. Science supported in United States for its utility since Republic began. Fear of inept political authority overcome by use of advisory panels for project review—"no subsidization without representation" as an established political principle in administration of science programs. National Science Board and National Science Foundation divisional committees, originally constituting a system of checks and balances, have evolved into normal administrative machinery.

   b. Creation of OST and transfer of NSF coordinating functions by Reorganization Plan No. 2 has given NSF greater, not less, range of potential policy influence. Policy a multi-agency and branch concern. NSF's range of potential influence is greater because NSF can be persuasive in its information and advice to OST.

5. Basic and applied science—complexity of problems unforeseen in 1950. Desirable lines for future policy:

   a. Avoid segregation of science into a single department. Science and policy are part of mission of every Federal agency.

   b. Do not confine agency activities to applied research alone. Basic research can make an agency's applied research program more productive; pluralism in sources of support for basic research is fundamental protection for scientific freedom.

   c. NSF should concentrate on its original purposes—support of basic research and science education. No danger that universities will seriously distort their programs to get grants. NSF responsibility for applied research should be exception, not rule.

   d. Closer tie in future between NSF, NIH, and Office of Education; possibility of single department seen.

B. Highlights of questioning

1. Fundamental organizational problems reason why NSF could not coordinate science activities of other operating departments:

   a. An agency headed by part-time board could not exercise continuous coordinating responsibility over other operating departments.

   b. Agency organized to deal with basic research would not understand major operational programs of Government.

   c. Isolation from President's political leadership made it impossible for NSF to exercise same kind of coordinating authority that Executive Office could.

2. Staff for NSB: "If the staff is not serving the Board's purpose, I think the Director ought to be asked by the Board to get a different staff." Suggested strengthening NSF staff to serve Board more adequately; also providing additional staff to work on policy content of problems and on general problems of science.

3. Working relationships between NSF and other agencies involved in research and education is "basically on sound lines."

4. Saw no alternative to NSF's responsibility for weather modification or Project Mohole.

5. Supported NSF decision not to assume responsibility for coordinating oceanography.

6. Establishing an environmental science department makes most sense of all proposals; does not know whether or not Commerce's role in this area should be strengthened.

7. Saw an eventual closer relationship between O. of E. and basic research programs of NSF and NIH—perhaps a loose confederation of agencies.

8. Spoke of open recognition of Federal support of higher education and how to implement policy to spread funds. Advocated continued project grants by NSF at not less than half present budget; agreed some shift may be necessary to make more institutional grants.

9. Concerning overlapping membership between National Science Board, NAS committees, PSAC, etc.:

   a. Saw no conflict of interest, and

   b. Saw no solution to problems caused by same first-rate persons serving in multiple capacities; did not believe this serious for NSB.

July 8, 1965

Witness: Dr. Alvin M. Weinberg, Director, Oak Ridge National Laboratory.

A. Highlights of statement: Future role of National Science Foundation

1. Summarized reasons in recent NAS report favoring greatly expanded NSF, particularly as a source of support of academic research in physical sciences.

2. Mission-oriented support of basic research is necessary (*a*) to maintain necessary environment for doing applied task, (*b*) to make new discoveries, (*c*) to solve problems arising in course of applied task.

3. Tolerant attitude of last decade and past level of academic basic research support cannot be maintained in mission-oriented agencies if support for applied missions does not continue to grow correspondingly. Spending for defense, atomic energy, and space already levelled off; therefore basic research which AEC, DOD, and NASA have been funding cannot continue to increase to levels necessary, with result that university physical and engineering sciences may be inadequately supported.

4. No corresponding problem regarding biomedical sciences. The need is recognized and NIH will continue to expand role as an NSF for basic biological sciences.

5. Three major sources for increased support of physical sciences suggested: (*a*) Expansion of commitment of NIH to physical sciences, e.g., in biochemistry, biophysics; (*b*) new agencies set up for problems such as urban transportation, air pollution, etc., should support some basic physical science, and, most important, (*c*) increase support by NSF.

6. Annual 15 percent increase of NSF budget for university research recommended; by 1970, NSF budget should exceed $1 billion. NIH and NSF foreseen as principal basic scientific agencies—NIH for biological sciences and NSF for physical sciences, especially in universities, and also other aspects of science not funded sufficiently by mission-oriented agencies. Eventually much more than half of university physical science to be supported by NSF (75 or 80 percent).

7. Annual NSF appropriation review seen as future forum for debate on basic research.

8. Government-higher education relationships will have to be debated as universities and Government laboratories compete for basic research funds.

B. Highlights of questioning

1. In light of stabilization of mission-oriented agencies budgets, helpful to have short-term agency guidelines for basic research support.
2. Figure of $1 billion for NSF by 1970 only an estimate—for NSF to become a "very, very major element" may need $1.5 billion or more. Fifteen percent rate of increase for NSF too low.
3. Relative support between physical and biological sciences should be closer to 1-to-1 basis rather than 3-to-1 or 4-to-1 ratio at present. Increased support for biological sciences emphasized.
4. Future new agencies likely to deal with new public problems having a systems character or social science character rather than physical science orientation.
5. Social sciences problems exceed in importance those of biological sciences but do not see where large sums of money can be spent in social sciences. Need a point of departure.
6. Competition between universities and in-house government laboratories a source of increasing difficulty—uncertain whether a serious problem.
7. SIE doing some things very well but not really serving as an operating service as does the U.S.S.R. overall science information service. Fault probably lies in inability of OSIS of NSF to coordinate science information for all Government agencies. COSATI doing good job with some of functions originally assigned to OSIS.
8. Putting NIH and NSF in one agency would dilute mission orientation of NIH with serious consequences.
9. Biological science support should continue by NSF but not at levels of physical sciences.
10. Study of civil defense problems at Oak Ridge a particular case arising out of interest of Professor Wigner, an Oak Ridge alumnus.
11. Not familiar enough with NSF to say whether present organization adequate to handle recommended growth. On present knowledge, believe overall structure could serve a $2 billion agency as well as one of present level.

Witness: Dr. Charles Kimball, President, Midwest Research Institute, Kansas City, Mo.

A. Highlights of statement

1. Not-for-profit institutes—
   a. Principally concerned with application of science and technology to economic growth and social change. Date back to founding of Mellon Institute in 1913; total employment 1964 was 11,000; research volume $150 million; influence very much out of proportion to expenditures.
   b. Effectiveness due to broad approach, objectivity, skill in blending scientific interest with commercial, economic, or mission objectives, and ability to do high-quality research within competitive costs and time limitations.
   c. No appreciable contractual or grants from NSF to not-for-profit institutes, because of NSF concern with basic academic research and because NSF has not regarded applied research as its responsibility.

2. Future role of NSF in technology:

a. Called for university programs to include training of "appliers of science" who can identify and solve problems relating to technology and economic growth.

b. Suggested special summer institutes as initial effort; later incorporate training programs in graduate business schools or engineering schools.

3. Other issues identified:

a. Need for improved technology in certain industries, particularly textiles, construction, metalworking.

b. Geographic distribution of R. & D. and influence of NSF on.

B. Highlights of questioning

1. NSF could be more active in transfer of knowledge by supporting training of people with this ability, and by assisting in exposing basic reseachers to applied research problems and vice versa.

2. Federal funding to assist emerging centers of competence could produce better geographic distribution of R. & D. activity. No criteria for selection to suggest—would hope they would be "other than political."

3. Research institutes might assist NSF in training "appliers of science."

4. Not-for-profit institutes have closer relationship with Commerce than with NSF.

5. No lack of clarity in split between functions of NSF and Department of Commerce.

6. It is the small corporation that needs assistance on technology utilization and transfer; large corporations have own resources.

7. Major task in attracting scientists was to sell idea that Midwest was neither intellectually nor geographically arid.

July 13, 1965

Witness: Dr. I. I. Rabi, Professor, Columbia University.

A. Highlights of statement

1. Covered applications of science to strengthen international relations of United States and open new avenues of communications.
2. Examples of importance of science to international relations:
   a. First Conference of Peaceful Uses of Atomic Energy in Geneva in 1955 where United States and Soviet scientists met was beginning of lessening of tensions between United States and U.S.S.R. Contacts there led to ratification of Test Ban Treaty.
   b. United States proposed formation of high energy physics laboratory by European nations; resulted in CERN.
   c. Scholarship program under NATO Science Committee.
3. Military departments, NIH, private foundations, and National Academy of Sciences support programs abroad or maintain relations with scientists from other countries.
4. No central office or organization exists in United States to maintain continuous international scientific communications.
5. Suggest NSF in cooperation with Division of Science Affairs in State Department expand international program and influence.

B. Highlights of questioning

1. Although Division of Science Affairs in State Department is primarily concerned with international participation in science, termed performance "consistently disappointing" due to lack of use by Secretary of State.
2. Agreed that scientific organization in State Department may be accepted with time and experience.
3. Believes NSF could do a great deal to improve the image abroad of the United States by publicizing the American educational system. As operating agency, can utilize fellowships, cooperative projects, visits.
4. With reference to good job the military agencies have done abroad through grants program, believe if NSF had the quality of personnel to do the job, "it would be easier to do a better job" because of traditional antimilitary sentiment of European scientists.
5. Supports NSF taking over international science needs which must be met as military budgets are stabilized or reduced.
6. On possibility of international cooperation with respect to the landing vehicle for Voyager project, thought it would be "very difficult." "* * * I would be afraid of it, particularly if it were international enough to involve the Soviet bloc * * *" due to differences such as industrial systems, writing blueprints, etc.

7. On evolution of science in China and India, believes Chinese could become the leading scientific nation. "Vital" that a top-level scientific team visit China.

8. Would like to see NSF have research support role comparable to DOD; DOD and AEC should not withdraw support.

9. Favored empirical approach on proportion of research NSF should support. Would increase support and evaluate situation year by year.

10. NSF should enter field of high energy physics "in a very big way"—to support building of a facility of energy higher than 500 million volts and to support additional facilities in lower energies.

11. Does not know whether research on brain and nervous system are receiving adequate attention.

12. On balance between social sciences and physical sciences, believes support is and should be forthcoming in any area which shows progress.

13. Pointed out social sciences get a great deal of support from private foundations; also that equipment needs in physical sciences so expensive, numbers of people supported may not be very big.

14. Science is ultimate challenge for the present and for the future. Thought competition between nations as symbolized by Sputnik had been good for United States in spurring us to a better effort.

15. Did not agree that the bigger problem was the needs of underdeveloped countries rather than spectaculars in the physical sciences. Thought advances in physical sciences would lead to devices which can be applied to other problems.

16. Saw NSF moving gradually into high and low energy physics, perhaps cooperating with AEC and gradually taking over.

17. Spoke feelingly on disadvantages to individual careers of taking positions in Foreign Service or Government—a very serious matter.

Witness: Hon. Francis Keppel, Commissioner of Education.

A. Highlights of statement

1. Office of Education-NSF relationships range from statutory requirements to informal contacts.

2. Informal contacts include staff consultations, informal interchange on advisory committees, and telephone.

3. O. and E. and NSF routinely refer proposals to each other in areas clearly the responsibility of one or other agency.

4. In new curriculum, teacher training institutes and fellowship programs, O. of E. has benefited from NSF experience.

5. Four major areas of O. of E./NSF mutual responsibility:

a. Construction of graduate facilities, under Higher Education Facilities Act of 1963—

(1) Program aimed to develop new centers of excellence in graduate studies.

(2) Managed by advisory committee of educators and representatives from NSF and PSAC.

(3) O. of E. support for facilities for teaching and research complementary to NSF support to research facilities.

(4) Ad hoc committee of O. of E., NIH, NSF, and NASA established February 1965 to coordinate various graduate facilities programs.

(5) Major differences in O. of E. and NSF programs besides NSF research emphasis:

(a) NSF can make matching grants up to 50–50 basis; O. of E. grants are limited to one-third. Administration seeking liberalization of current matching requirements. Amendment sought for discretionary authority rather than a flat amount.

(b) Seventy percent of O. of E. program nonscience.

b. Improvement of qualifications of elementary and secondary school teachers:

(1) Institutes program supplements training in science and mathematics. O. of E. institute program originally for modern foreign languages; in 1963 extended to teachers of English to non-English-speaking students, and in 1964 to above programs and seven new types: teachers of history, geography, reading, English, disadvantaged youth, school library personnel, and educational media specialists.

(2) Intent and implementation of O. of E. institutes similar to those of NSF.

(3) Possible overlap in support for institutes in geography.

c. O. of E. graduate fellowship programs—$2,500 each to institution and to student:

(1) Congressional intent to provide fellowship support to new or expanded doctoral programs. Tried to spread available assistance as equitably as possible.

(2) Program fundamentally altered by Congress in 1964:

(a) Number of fellowships awarded raised from 1,500 in 1964–65 to 3,000 in 1965–66, 6,000 in 1966–67 to 7,500.

(b) Awards vacated made available to its institution for reallocation.

(c) Half of fellowships for fiscal year 1965 and two-thirds in fiscal year 1966 released for allocation to doctoral programs which had capacity to enroll additional students with existing staff and facilities.

(3) Policy in awarding Ph. D. fellowships changed upon recommendations of a statutory advisory committee and a group of university advisers to provide for allocation in concentrated blocks to institutions exhibiting promise of excellence.

(4) Criteria for determination of promise of excellence (*a*) judgment of peers, (*b*) proposal reviewed as institutional whole by overall advisory committee.

(5) Distribution of program, 60 percent in humanities, education, and social sciences, 40 percent in biological, physical, and engineering sciences.

d. Other legislation authorizing O. of E. to conduct research in education—

(1) Handicapped children.

(2) Modern foreign languages.

(3) New educational media.

(4) Adult and vocational education.

(5) Cooperative research program—most extensive and one with which NSF is most involved.

6. Criteria for review: significance research design competence of staff and facilities, and economic proficiency of proposed project.

7. Curriculum improvement program—may concern whole curriculum, or a particular course or subject at any level. O. of E. tries to identify and stimulate projects to fill gaps created by specialized courses or curriculum or provide alternatives to existing curriculum improvement effort.

a. O. of E. and NSF agree on necessity to have available several types of new curriculum which local school authorities may use as a guide.

b. Wide variation across country in State control of curriculum; State legislative actions usually limited to a particular subject.

c. Coordination between NSF and O. of E. on curriculum improvement by (*a*) appointment of NSF staff member to O. of E. curriculum improvement review panel, (*b*) joint site visits by two agencies, and (*c*) joint review and funding of proposals relating to both.

8. NSF and O. of E. relationships which need further consideration—

a. Continued cooperation in course content improvement projects, to insure curriculum choice and experimentation at local level.

b. Institute and curriculum improvement programs of both agencies will need to be more intimately related.

B. Highlights of questioning

1. Spoke of the applicability of new techniques under educational media program. Was asked to supply information about research in program instruction, educational TV, and satellite communication.

2. O. of E. fellowship support of 60 percent to humanities and social sciences intended to reflect balance between numbers of college teachers in humanities and social sciences on one hand and sciences on other. Since O. of E. program is intended to increase number of college teachers, a statement of intent of applicants is requested—it is not an indenture.

3. Do not believe, putting all various agencies and fellowship programs together, that the need and supply for teachers in both social sciences and physical sciences is being balanced.

4. Supported present 60–40 balance for distribution of additional funds.

5. Agreed to obtain for record amount of total support, for graduate education and institutions which comes from all Federal agencies. Amount of State contribution also requested. Undergraduate totals as well as data on elementary and secondary levels also mentioned.

6. Did not say whether percentage of NSF fellowship support should be increased. With respect to O. of E., needs more money for libraries. Did not think it wise to greatly increase number of Ph. D. fellows in title IV of NDEA.

7. Opposed setting up a Department of Education encompassing Federal education functions:

a. Various agencies have used university resources for their goals; should not be prevented from direct relations.

b. To channel all activity through a central office would "probably slow up the paperwork."

July 14, 1965

Witness: Dr. Harvey Brooks, Dean, Division of Engineering and Applied Physics, Harvard University.

A. Highlights of statement

Statement directed to (1) criteria for support of basic research; (2) NSF role as viewed by individual investigator; (3) NSF statistics, and (4) role of NSF in applied sciences.

1. Criteria for support of basic research.

a. For views on subject, referred to paper in Academy report, "Basic Research and National Goals."

b. Proposed three classifications of basic research—

(1) Establishment basic research—performed in Government laboratory or Federal contract research centers.

2. Programmatic basic research—"big science." Two types: (*a*) Centered around complex and expensive equipment or (*b*) centered around cooperative attack on a problem by scientists from different disciplines.

(3) Academic research—both basic and applied research in connection with training of graduate students or other research personnel. Two types: (*a*) Mission-oriented academic research and (*b*) discipline-oriented academic research. All qualified students should be supported, at levels set by national policy. Fields to be supported should in general be determined by scientists, in contrast to programmatic research where applied needs take precedence. Need to be only indirectly oriented toward national needs.

c. Funding of establishment and programmatic research are more explicitly political than of academic research, although the total of academic research is also political.

d. NSF current funding of academic research should rise from approximate level of 13 percent of the total to 25–35 percent, with not more than 80 percent in any one field to come from NSF, to preserve competition. Percentage of NSF support suggested established from a number of qualitative considerations—a "visceral feeling"—three times the present 13 percent and still under 50 percent.

e. While NSF may have been too conservative in past in developing new fields or transferring funds, would not like to see it err in other direction.

f. "Proposal pressure" still best measure of relative needs and should continue as primary although not sole basis of judgment in allocation of funds within basic research support grants.

g. Science development program will lose its purpose if basic research support grants are not increased to take care of new capabilities which program is expected to create.

h. Non-Federal sources of support for university basic research and "little science" have kept pace with Federal funding. Proposition of Federal funding has increased for university research, due to increases in applied research. Federal proportion of funding for industrial R. & D. has increased from about 40 percent to 60 percent in last 10 years. Expect to find out more about State funds from the PSAC summer study.

i. Criteria for establishment research should be "primarily a decision of the local management" influenced by (1) Agency dependence on advances in basic science, (2) relevance of basic research to long-range goals of agency, (3) integration of basic research with the applied research, (4) past performance of agency in its mission, and (5) competence of personnel for basic research.

j. Criteria for establishing new programmatic research institutions: (1) Availability of scientists who will support program, (2) inability to meet need through existing facilities, (3) insufficient funding, (4) expected novel and intrinsic intellectual significance of scientific results, (5) contribution to other areas of basic science, (6) potential contributions to future technology, and (7) contributions to education and training of future scientists and technologists.

k. Criteria for academic research: (1) Promise of significant scientific results from project, (2) novelty, originality, and uniqueness of work proposed; (3) degree to which results likely to influence other research, (4) educational value of work, and (5) possible relevance to future applications.

2. NSF role as viewed by individual investigator:

a. Academic research should be NSF's major concern.

b. NSF should support programmatic research only to provide opportunities to university scientific community not otherwise available.

c. Project support should continue for academic research with a better balance between it and institutional grants.

d. Project support also broadens perspective of panel members in own fields, makes them aware of projects elsewhere and to avoid undesirable duplication or overlap, and recognizes outstanding performance of investigators wherever they are, especially in smaller or lesser known institutions.

3. NSF statistics:

a. NSF leads world in collection of statistics.

b. Suggested areas of improvement:

(1) More effective use of sampling.

(2) Closer ties between planning and statistical groups with program officers in NSF.

c. Needs of OST and of Congress will strengthen data collection program by giving it focus and policy relevance.

4. NSF and applied science: NSF should support applied science only where it would make important contributions to advanced training of technologists.

B. Highlights of questioning

1. Division of support between NSF and mission-oriented agencies varies with dependence of the mission on basic research. Suggest 60- or 70-percent support by mission-oriented agencies for solid state physics while in astronomy, NSF share might be 70 percent.

2. Individual excellence should receive higher priority in academic research than in establishment research.

3. Very little institutional basic research today done without outside funds from private or Federal sources. University and Federal funding so merged, difficult to separate.

4. All academic research is selected in some fashion. "Even that which is selected by the individual is selected in a sense." "* * * the idea that the university faculty member is completely free to do anything that he wants is inversely proportional to the cheapness of what he wants to do." A certain amount of flexibility is provided by institutional base grants.

5. Academic research criteria are applied "somewhat intuitively, perhaps not explicitly" by NSF panels and university deans and department chairmen.

6. Did not know whether NSF methodology in statistics is up to date. Has heard comments that methodology is good.

6. Did not know whether statistical problems could be met by funding. Believed more funds necessary in next 5 to 10 years but uncertain how funds would be used best. PSAC summer study may provide some additional information.

Witness: Dr. James A. Shannon, Director, National Institutes of Health.

A. Highlights of statement

1. NSF position central in structure of Federal science organization. Any changes in concept or functions will affect ability of mission-oriented agencies to discharge their roles and, in fact, will make necessary modifications in the total Federal science support role.

2. Reviewed present NIH activities showing interrelationships with NSF programs and responsibilities, described joint NSF–NIH effort, and discussed present and future role of NSF in science and education.

3. Present NIH activities and interrelationships with NSF:

a. Primary NIH mission is understanding of behavior and biological requirements for health and for an understanding of disease. NIH has major role in support of research in institutions of higher education and an indirect through major role in graduate education, through principle that effective research support implies an obligation to assure manpower resources for continued future growth.

b. NIH research arm of PHS. Institute concept stems from creation of National Cancer Institute in 1937; broad authority for extramural research project grant support made available in

Public Health Service Act of 1944. By time of creation of NSF in 1950, seven of nine present research institutes had been established, and Federal Government was heavily involved in support of academic sciences through mission-oriented agencies.

c. Nature and extent of NIH–NSF relationships: Collaboration on (1) specific scientific studies; (2) terms and conditions of support for research, training fellowships, and facilities programs; (3) use of peer group review system for academic research; and (4) on coordinating activities and programs focusing on same institutions.

4. Examples of NSF–NIH cooperation mentioned at top, intermediate, and working levels. Informal and formal relationships noted. Purposeful overlap in programs to avoid inadvertent gaps. NIH–NSF have jointly financed studies re scientific manpower, graduate education, and university activities of common interest.

5. Future role of NSF:

a. Continuation of present support patterns with flexibility.

b. NSF should fill gaps and deficiencies in science structure left by mission-oriented agencies.

c. Looks to NSF to support science as a national resource and to carry out "balance wheel" role.

d. Aspects of NSF, NIH, and O. of E. relationships in Federal support for academic sciences:

(1) Although O. of E. dominant in training and construction of educational facilities, role in support of science is minor.

(2) In face of declining DOD expenditure, NIH and NSF support is critical for university research.

(3) NIH future growth seen in—

(a) Basic science research relating to major diseases.

(b) Bringing physical, behavioral, and mathematical sciences in closer relationship with biomedical sciences.

(4) NSF increasingly will be involved in direction and management of large-scale science projects; this is sound only so long as increasing resources to growth of academic research are available. Of concern is the constantly rising cost of large-scale science projects.

e. Contradictions in NSF budget:

(1) Increased support for science development program concurrently with cutbacks in NSF project support.

(2) Inadequate attention to long-range consequences of certain funding decisions.

f. Optimum utilization of intellectual resources will determine position of United States in future.

B. Highlights of questioning

1. NIH/NSF show surprisingly little overlap. Only a small portion of total proposals could go to either. All large program expenditures receive at least informal joint consideration. Fifty percent of NIH funds go to professional schools related to health professions; 25 percent to universities, in areas of biophysics, biology, veterinary schools, etc. NSF clientele predominantly nonmedical in universities.

2. NIH only agency supporting behavioral sciences until NSF established. Has continued through Mental Health Institute and recent Institute of Child Health and Human Development.

3. NIH has no category of support for social sciences. However, about 10 percent of total resources being spent in psychology, cultural anthropology, etc., which are areas of social sciences relevant to health.

4. Establishment of environmental sciences group "highly desirable."

5. Both NIH and NSF support psychologists.

July 15, 1965

Witness: Dr. Augustus B. Kinzel, President, National Academy of Engineering.

A. Highlights of statement

Statement on Federal support of engineering and the need for increased NSF support.

1. Need for Federal support of engineering

a. Application of science through engineering stimulates the economy.

b. Although engineering primarily is responsibility of industry, Government support essential when—

(1) Objective is for a governmental function, as defense.

(2) Subject is so broad that one organization cannot finance.

(3) Costs of studies on special use requirements for materials cannot be justified by industry.

(4) Basic engineering advances are needed.

2. Need for increased NSF support

a. Proportion of NSF engineering support unchanged from fiscal year 1964 to fiscal year 1966 (11.2 percent versus 11.8 percent) despite announced intention of increased emphasis.

b. Government support of engineering sciences was 7.4 percent of total Federal basic research for fiscal year 1966; for fiscal year 1965 it was 6.6 percent.

c. Noted lack of engineers on Foundation staff.

d. "Woeful lack" of NSF engineering fellowships at graduate level.

e. Suggested budget increase and executive action to increase engineering research.

B. Highlights of questioning

1. "Executive action" refers to formal or informal NSF directives concerning increased engineering support.

2. While formation of National Academy of Engineering will increase emphasis on engineering, this will take time.

3. Does not agree that United States has lost world lead in applied science.

4. Emphasis on basic research may have been one of factors in lack of interest of NSF in engineering.

5. Believes United States still preeminent in engineering. Quality, not number, of engineers is the problem.

6. Agrees NSF's role in mission-oriented basic engineering should be only filling gaps. NSF has important role in fundamental engineering and systems engineering.

7. Agreed with Dr. Brooks concerning applied science education role of NSF in advanced technological training and retraining. Training should also extend to fundamental engineering.

8. While industrial scientists and engineers are fairly well represented on panels of NSF, representation could be better.

9. Mission agencies have responsibilities to retain technologists and engineers for specific functions; updating technological knowledge should be a function of NSF.

10. Difficulties of training engineers in design might be partially met by specific designation of certain number of fellowships for this purpose.

11. Concerning an interim program for engineers similar to that for doctors, referred to existing cooperative education programs.

12. NAE hopes to advise NSF as does NAS.

13. NAE would accept responsibility for applied research; task of actually doing the research would be referred to the National Research Council.

14. Believes more engineering representation helpful to NSB.

(NOTE.—Statement by Dr. Leland Haworth in testimony of August 19, 1965, presents certain data which is at variance with Dr. Kinzel's testimony.)

Witness: Dr. J. Herbert Hollomon, Assistant Secretary of Commerce for Science and Technology.

A. Highlights of statement

1. Commerce-NSF relationships:

a. Formal arrangements:

(1) Through national research programs, e.g. NBS, Weather Bureau, and USCGS participation in IGY, Antarctic research program, International Indian Ocean Expedition, United States-Japan cooperative science program, and International Year of the Quiet Sun.

(2) Through NSF initial funding of new programs in Commerce, e.g., National Standards Reference Data System and Clearinghouse for Federal Scientific and Technical Information.

b. Wide range of casual contacts between Commerce and NSF analytical and funding groups.

2. Questioned NSF role for applied science or operating large projects, except in fields of education and science information:

a. Weather modification: (1) Believed assignment of responsibility to NSF for information gathering on weather modification has resulted in loss of initiative by other agencies to develop programs. Matters now being studied by Commission of National Science Board and Interdepartmental Committee for Atmospheric Sciences.

b. Atmospheric research: (1) Questioned support of National Center for Atmospheric Research wholly by NSF. NCAR has tended to become a "creation of NSF without either educational or mission responsibility."

c. Meteorology: (1) Large-scale program of worldwide weather observations will be necessary to determine whether improved

predictions are possible. Should this be responsibility of NSF or of agencies "that will have to put the results to work."

3. NSF's long-term objectives should be focused on building the "institutions of science," rather than on solution of specific scientific questions.

a. NSF view of science, as an institution, too restrictive:

(1) Should have greater concern with science of people and their behavior, with institutions people create, and with interaction of people with environment and society.

(2) Should focus national efforts on problems such as transportation, communications, shelter, urban society, education, industrial production, and economy.

b. Educational institution-building:

(1) Need broader base of support for greater variety of scientific subjects—urged development of many centers of excellence.

(2) Support for institutional programs should be expanded and strengthened.

B. Highlights of questioning

1. Believed NCAR should be supported by other interested Government agencies in addition to NSF.
2. Weather research should be supported by all agencies who have a "real interest" in it.
3. Did not say who should have scientific responsibility for world-wide meteorological study. Suggested this is an appropriate question for "this committee" to examine: Should NSF (1) fund and/or (2) operate experiment.
4. Agreed that emotional response to atom bomb responsible for emphasis on physical science.
5. Agreed that 19th century interest in science was motivated by need for food and agricultural research.
6. Urged consideration of who should have predominant role in contemporary science problems closely tied to the economy, e.g., industrial production, transportation, communication, urban development, house and building construction.
7. Agreed consideration should be given to need for some other agency (suggested by Mr. Brown) to focus on problems dealing with the relationships between science, the people, and the economy.
8. Suggested three steps to advance a new program: (1) establish institutions throughout country to carry on program, (2) provide for support for research, and (3) provide means of connecting research with the recipients. State Technical Service Act would provide means to implement step (3).
9. Did not give opinion whether NCAR should have been included in the environmental sciences group. Said present situation "not necessarily" criticizable.
10. Deferred opinion whether or not NSF should have responsibility for Mohole. Did not know whether environmental science grouping would be a "fairly logical place" for Mohole.
11. Did not know of consideration to possibility of leasing Federal facilities for industrial research. Mentioned limited research associate program where industrial associates can utilize facilities of NBS. Will try to furnish information on industrial firms or nonprofit organizations being allowed to use Government facilities.

July 20, 1965

Witness: Dr. Herman Pollack, Acting Director, International Scientific and Technological Affairs, Department of State.

A. Highlights of statement

Discussed (1) interaction of science with foreign affairs; (2) how State Department deals with science; and (3) NSF involvement in international activities.

1. Science and foreign affairs:

a. Successful foreign relations requires utilization of all resources, including science. Hesitance to so use science caused by fear of identifying science with politics thereby destroying its integrity.

b. If interests of good international science and good foreign policy are contradictory, neither scientific nor political goal will be attained.

c. Suggested authority comparable to that in Public Law 86–610, July 12, 1960, for international cooperation in health research be obtained for international status of science in general on behalf of President or an agency such as NSF.

2. NSF's role in international participation: NSF might supply "seed money" for international activity of agencies until these can be continued with other funds.

B. Highlights of questioning

1. State Department has no authority to transfer funds to NSF; does transfer $25,000 annually to National Academy of Sciences for advice on the Department's international scientific programs.

2. NSF and State cooperate on scope and size of Antarctic program; NSF acts at State's request on United States-Japan cooperative science program. No nation-by-nation review made to identify needs or roles nor is there an organization to do so.

3. Only two specific instances of employment of Public Law 86–610 recalled. Under consideration with respect to medical science in Japan.

4. Will supply record of funds in research grants to foreign investigators justified by their expected contribution to U.S. efforts—for NSF, military, and other agencies. Admitted State Department inability to provide guidance to NSF.

5. Have predictions for Western Europe of future position in "economic and political spectrum" by analyzing support for science education and industrial research; do not have for China or U.S.S.R.

6. Could not say whether China might become top scientific nation in world.

7. Guidelines for behavior of delegates at international conferences vary according to the organization. State Department controls statements of policy of Government agencies sending delegation or representatives to international meetings.

8. Information on State Department funds for scientific cultural exchange will be supplied.

9. Exchange program with Soviet Union and bloc countries carried out by National Academy of Sciences with NSF funds and State Department advice. Will find out if funding adequate.

10. Teachers exchange program carried on by Bureau of Cultural Affairs. Both O. of E. and State Department fund teachers exchange programs. To furnish a summary.

11. Science attachés maintained in 16 countries. Present funding adequate in all but three posts.

Witness: Dr. Pendleton Herring, President, Social Science Research Council.

A. Highlights of statement

1. Emphasized social sciences as great American development. Touched on (*a*) social science program in NSF, (*b*) broader view of Social Science Research Council, (*c*) more stable support for social sciences, (*d*) more effective representation of the social sciences, and (*e*) significance of social sciences for future—their national and international contributions.

a. Social science program in NSF:

(1) Received token support until Sputnik.

(2) 1960 background paper on creation of NSF Division of Social Sciences seen as move to attract support proposals from leading social scientists.

(3) Grants in social sciences have increased from $2 million plus for 1961 to over $10 million in 1965. While rate of increase has been steep, NSF support of social science research is very modest.

b. Broader view of social sciences: (1) Federal Government a great consumer of social science. Support has been modest—on occasion too much supplied too fast, and cut off too soon. Mission-oriented agencies support of social sciences only a byproduct of their activities.

c. Increasing stability of support:

(1) Problem is not the absolute amount of support but the conditions under which given—continuity and spirit.

(2) Hopes for direct and open support of social sciences.

(3) Social Science Research Council took lead in bringing together university personnel and private foundations to build up centers for social sciences.

(4) Social science research can produce results relatively quickly, given a sense of purpose, and reasonable financial support and national need.

d. More effective representation of social sciences:

(1) Broaden base for social science support in NSF.

(2) Create foundation for humanities and the arts—some overlap exists between humanities and some social science fields.

(3) Called for clear relationship between consuming public and organizational structure set up to serve it. Suggested multiple support pattern.

(4) Social sciences should be represented on PSAC and on National Science Board.

B. Highlights of questioning

1. "By and large" NSF has tended to select social science projects which lend themselves to scientific method.

2. To extend that it is possible, quantification methods are used. Tendency is to seek objective and analytical approaches.

3. Broad consensus of need not required to produce results. Cited efforts of Wesley Mitchell through National Bureau of Economic Research on study of business cycle.

4. Social science needs—

(a) Organization to make best use of available funds.

(b) Strengthened departments within universities.

(c) More social scientists; cannot now meet requests from abroad for specialists.

5. Atom bomb seen as sociological and political problem.

6. Social science proposals presented to NSF reflect assumptions of what would be favorably received. As scope of programs is broadened, proposals expected to increase.

7. Agreed low level of support might be laid to social scientists for not bringing the problem to a head.

8. To extent that underdeveloped countries have infrastructure on which to build, social science contributions of United States can compete with those in physical sciences in competition with Communist bloc.

9. In general, United States needs to augment support of social sciences, both because of national and international aspects.

10. Could not say whether NSF is proper body to provide increased support for basic research in social sciences. Suggested inviting comments from well-informed persons.

July 21, 1965

Witness: Dr. Walter Orr Roberts, Director, National Center for Atmospheric Research.

A. Highlights of statement

Discussed National Center for Atmospheric Research and its relationship with NSF and with universities.

1. The National Center for Atmospheric Research (NCAR):

a. Study of atmospheric science developed after World War II when analytical tools were developed, particularly the electronic computer.

b. "Interdisciplinary" approach characteristic of atmospheric sciences.

c. NCAR origin was NAS study of 1958 which recommended creation of a National Institute for Atmospheric Research. NCAR established in 1960, by NSF, through a contract between NSF and University Corp. for Atmospheric Research. Management details reviewed; 13 original university members in NCAR, 21 today.

d. Facilities and visitor programs of NCAR open to all atmospheric scientists from member and nonmember universities, from private nonprofit and Government laboratories, both here and abroad.

e. Staff now 380, about two-thirds eventual size.

f. NCAR devoted to basic research, although need oriented:

(1) Laboratory of Atmospheric Sciences researches atmospheric dynamics, cloud physics, and atmospheric chemistry.

(2) High Altitude Laboratory studies atmospheres in outer space, and extraterrestrial influences on earth's atmosphere.

(3) Advanced study program—sponsors postdoctoral study in various research fields.

(4) Facilities program provides balloons, aircraft, and computers.

2. NSF-NCAR relationships:

a. NCAR has maximum scientific freedom.

b. Difficulties caused by insufficient funding, by contract restrictions, and regulations.

c. Saw need for experimental global observing network to be managed by Environmental Science Service Administration.

d. Discussed need for supercomputer, 100 times more powerful than any existing computer.

B. Highlights of questioning

1. University members of NCAR provide representative to council and/or trustees, and a cash contribution. Members must meet criteria for graduate instruction offered in atmospherics.

2. NCAR maintains wide contacts with agencies involved in weather science; NCAR scientists available to advise Government, industries, universities—anyone with scientific need to know about NCAR research.

3. Creation of NCAR reflects national realization of need for research in atmospheric sciences. Continuing NSF support of NCAR justified so long as it fills basic research needs not met otherwise.

Witness: Rev. Theodore M. Hesburgh, President, University of Notre Dame.

A. Highlights of statement

Statement presented a noncritical review of Foundation activity based on 11 years on the National Science Board and as president of the University of Notre Dame for past 13 years.

1. Board-Director relationships:

a. Harmonious relations between Board and Director.

b. Board has been well informed in detail of actions taken by Director under delegated authority.

c. Revised Board committee structure already proving useful. Sees Board as becoming even more effective in strengthening national science.

2. Concerning substantive aspects of NSF operations:

a. Common agreement that basic research support has had "enormous beneficial influence" on "national science enterprise."

b. Social science research support by NSF reviewed. Experience has shown that one agency can support both social and natural sciences. Problems and methodologies may differ but objectives and intentions are similar. In all fields, research is university-based, and standards and criteria "very much alike."

c. NSF educational activities of "very great significance to our national interest": (1) Fellowship and traineeships programs; (2) improvement of education through institutes to improve the teachers, and curricula revision. Two problems of teacher training: Half of high school teachers of science and mathematics have not applied for the teacher programs and many of new teachers are inadequately prepared.

3. Relationships between NSF and institutions of higher education—

a. Harmonious and mutually beneficial.

b. Foundation's careful and just evaluation of project proposals and honest administration recognized.

c. Institutional concentration of funds a problem. Need to maintain and support high-quality institutions and also to help raise levels of other institutions. Science development program has great promise.

B. Highlights of questioning

1. Concerning teaching by fellowshipholders, university experience has proved advisable not to have first-year graduate students teaching; also a danger that teaching may slow research and dissertation work. "* * * one of greatest needs in graduate students in all departments today is to get students through. Some students become perpetual students * * *."

2. Believes a majority of graduate students at Notre Dame go into teaching except in certain areas of chemistry and engineering.

3. Approved making Director a member of Board.

4. Special committees meet monthly; Board now meets about six times a year.

5. Staff turns out "enormously well prepared" papers. If special information is desired, have only to ask the appropriate staff person through the Director.

6. No problem getting information from people who are advocating a position. Usually alternative possibilities are offered to accomplish a purpose.

7. Concerning balance of representation on Board, what is really needed are "people who will take public responsibility with some background and knowledge and expertise on the total scientific effort as regards education and research."

8. NSF relations with NAS, OST, PSAC—very amicable relations with Academy which has guided Board in many areas; haven't felt any great tension in relations with OST and PSAC; "enormous support" from President's Science Adviser. PSAC and Federal Council offer "sounding board" for decisions which Foundation must make.

9. There ought to be relation between geographical distribution of centers of excellence and Federal research funds. NSF research distribution shows "fairly good correlation."

10. Always a danger that concentration of Federal research funds in certain areas will affect adversely others. Science development program expected to spread research and research support; must continue to support excellence.

11. Drop in percentage awards to social sciences since 1962 in relation to physical sciences not a reflection of waning interest but rather of fixed commitments in physical sciences.

12. Since social sciences do not require expensive physical equipment, more assistance and attention could be given to smaller colleges and universities in this area.

13. Board not too large; has great cohesion, very good committee structure, good geographical spread.

14. Board constantly concerned about need to support large projects such as Mohole, but aware that such support cuts into NSF's primary purposes with regard to basic research and education.

15. NSF must assume responsibility for gap filling. No other agency can.

16. No problem seem in Director's being responsible both to the President and to the Board.

17. President's Science Adviser attends Board meetings only on special occasions, when there was a question about his office or on broad matters of national policy.

18. No insurmountable conflicts between Board and PSAC or OST.

July 22, 1965

Witness: Dr. S. Dillon Ripley, Secretary, Smithsonian Institution.

A. Highlights of statement

NSF-Smithsonian relationships for basic research roles and the Science Information Exchange.

1. Basic research role of Smithsonian:

a. Smithsonian in basic research since establishment; a "forerunner" of modern graduate laboratory. Maintains "general concern" for basic research by in-house activity.

b. Research focused on specific needs, e.g., national program of salvage archeology in western United States in cooperation with Interior Department, on activities of Smithsonian Astrophysical Observatory and its Radiation Biology Laboratory, National Zoological Park, and the Smithsonian Oceanographic Sorting Center.

c. Present missions of Environmental Science Services Administration, Fish and Wildlife Service, and NASA originated in Smithsonian.

d. Program of grants of excess currencies for museum programs and relevant research recently started.

e. NSF support for Smithsonian activity include (1) funding visiting research appointments for undergraduate science students, (2) support of Science Information Exchange, (3) projects in oceanography, (4) Antarctic research, (5) endorsement of activities by NSF panels, and (6) use of Smithsonian staff to review proposals.

2. Basic research role of NSF:

a. Smithsonian concerned with institutional needs; NSF is concerned with national needs.

b. Agreed on necessity for increase in NSF budget to billion dollar level: (1) Supported 15 percent national basic research growth rate; NSF budget will have to be increased even more to accomplish its objectives; (2) agreed that mission-oriented agencies cannot be expected to support adequate basic research; (3) spoke to national need to support basic research to the limits of the public's need for new knowledge; (4) NSF must retain administrative freedom in management of funds.

3. Science Information Exchange:

a. Traced development since 1949 and current need for highest priority support.

b. Since NSF assumed total funding in 1963, former operating board of SIE is now advisory; policy, scope of activity, and procedures set under NSF agreement with Smithsonian.

c. Described "current awareness" information problem and rise of little "invisible colleges"—small groups of specialists in advanced fields who maintain mailing lists to keep informed of activity within field.

B. Highlights of questioning

1. Mission agencies need not confine activities to applied research; saw basic research as spinoff of benefits of applied work. Nor should NSF support applied research on theory it would sharpen objectives.
2. Discussed process by which SIE and individual investigator are kept reciprocally informed.
3. Wide public coverage given space program not now accorded to other aspects of science. More a lack of funds than of authority.
4. Lack of sufficient progress in certain fields not due to organizational problems. Was referring to lack of results rather than effort toward achieving objective.
5. About 35 percent of Smithsonian budget goes for natural science and research in addition to grants from agencies for performing certain activities.
6. Smithsonian's astrophysics activities "keeping up very nicely with general field."
7. Would increase financial base for basic research for which 15 percent growth would be applied.
8. Called "critical" the 5-year lag to achieve base which results from a 15 percent annual increase.
9. The subcommittee can help NSF achieve its goal by setting a "mood of generous willingness to support the science rather than specific details" of accounting procedures, etc.
10. Concerning coordination of SIE activities with other agencies, SIE focuses on basic research in process, while other agencies deal with completed basic and applied research and technology.
11. Prohibition against transfer of NSF funds for research to other agencies has adverse effects. Resulted in Smithsonian setting up its own grant program for original research, with selection made by ad hoc panel. System operating satisfactorily except that necessity to duplicate procedures of NSF has increased cost of program.

(Note that this is the only time in the hearings that congressional prohibition of NSF transferring funds to other agencies was brought up.)

12. On question whether information storage and retrieval should be centralized, deferred to COSATI. Inclined to allow competing groups. Problem of such urgency that there should be more rather than fewer attempts to solve problems.
13. Uncertain whether social science research projects included in SIE.
14. Criticism in Elliott Committee report referred to problems of input and feedback, due to failure of agencies to cooperate thereby reducing end use. Report has served to spur efforts by COSATI toward urging more complete participation.

July 27, 1965

Witness: Dr. Eric Walker, Chairman of National Science Board and President, Pennsylvania State University.

A. Highlights of statement

1. NSF responsibility and control:

a. NSF responsible to Congress through hearings and to Administration through the Director, Science Adviser, and Budget Bureau.

b. NSF responsibility to scientific community through National Science Board and advisory panels not as clearly defined or as continuously maintained.

c. Judgment by "peers" may have man judge proposals of friends or associates; dangers obvious but no alternative.

d. Reorganization Plan No. 5 of 1965 intended to increase flexibility in NSF relations with scientific community; uncertain of impact of divisional committees on operations under new arrangements.

e. Operation of National Science Board:

(1) National Science Foundation Act gave to Board major planning, policy, and operating responsibilities; some since delegated to the Director. Board "may delegate authority but not responsibility." Cannot delegate responsibility for (*a*) establishing general plans for NSF; (*b*) deciding direction NSF should go; and (*c*) making major decisions where specific Board concurrence is required.

(2) Since 1963, Board reorganized itself by establishing committees (*a*) to deal with present balance of effort, (*b*) to do planning for future, and (*c*) to deal with current administrative problems.

(3) Further steps believed necessary to maintain Board effectiveness:

(a) Assignment of full- time staff to Board—possibly one staff member for each of the Board's committees—among functions would be preparation of policy papers for committee discussion and action.

(b) Make Chairman of Board a full-time position—Chairman to establish policies and represent NSF in scientific community and among other Federal agencies; the Director to have full-time responsibility for management of operations. Could be implemented by making present Director the Chairman and put Deputy Director in charge of operations.

(c) Believe NSF has grown to point where there must be a "clear cut" separation between policymaking and operations.

(d) Full-time staff might assist in channeling divisional committee recommendations for Board consideration.

2. Uneven distribution and "apparent" concentration of NSF funds a problem:

a. No simple cure for the spiraling situation; both difficult and undesirable to fight excellence.

b. NSF programs to help correct situation are (1) science initiation grants, (2) institutional grant program, and (3) science development program. These means preferable to alternative of placing top limit on percentage of university's funds from Federal Government.

3. NSF and engineering:

a. Speaking as former president of Engineers' Joint Council, believe engineering has not received proper recognition from NSF.

b. Lack of understanding of true nature of engineering in Government and engineering educational institutions.

c. Federal Government role seen as financing and supporting necessary engineering design and testing of devices and systems where there is no immediate prospect of profit or major interest by a single company. Examples: instant mail delivery, transportation, water retrieval.

B. Highlights of questioning

1. Could not say whether it would have been better to strengthen Board earlier, rather than turn over authority to Director.

2. No specific date mentioned when Board's workload had reached a point where it could not function as it should. As NSF added programs and activities, work of Board increased—growth like an inverted pyramid.

3. His suggestions for Board revision could pose difficulty—clear definition of jurisdiction of staff needed as well as compatibility between Chairman and Director.

4. Legislative action to establish Board staff not believed necessary.

5. Agreed that complete separation of policy and operations impossible, but pointed out policy needs to be based on long-run considerations, while operations deal with problems of today.

6. Board may be at fault for lack of closer communication between Director's policy planning staff and Board's planning staff.

7. Confirmed existence of definite relationship between Federal funding and industry both being attracted to the best universities.

8. Existence of R. & D. in certain area not thought a factor in NSF distribution of funds to institution there through science development program.

9. Distribution of funds to industry has only indirect effect on institutions in that area.

10. Imbalance in distribution of Federal research funds cannot endanger existing centers of excellence—"* * * the excellent universities are so strong that things like this really cannot affect them."

11. Balance among fields of science represented by present Board "is very good."

12. Expressed personal belief that Board has been "very timid" in support of social sciences and also engineering. Establishment of Foundation for arts and humanities should make clear that social sciences are an NSF concern.

13. NSF role in solving major engineering problems is decision for Congress, the Board, and Administration to share. Believe NSF "could" and "probably should" do it. Real problem was absence of decision by Congress that these matters merited concern.

14. Was not aware of unresolved disagreement between Board and Director. In event of impasse about an activity, Board could insist on line item in request to Budget Bureau and the Congress.

15. If disagreement between NSF, Budget Bureau, and President's Office, disagreement would be resolved at President's Office level.

16. (Answered by Dr. Haworth.) Budget Bureau has turned down various NSF requests for program support. No single denial was a "significant" fraction of a total budget. New programs have been turned down or postponed. Reductions made for financial reasons.

17. Agreed that Board has not exercised its full authority. "Instead of innovating, it has been filling needs."

18. Agreed that Board's role with reference to overall scientific interest of Nation limited by (1) inability to dispute Presidential decisions on major expenditures and (2) failure to represent the overall scientific community of Nation including industry as well as universities and institutes.

Witness: William T. Knox, Chairman, Committee on Scientific and Technical Information of Federal Council for Science and Technology.

A. Highlights of statement

1. Statement dealt generally with NSF's relation to Federal Government's overall information program. Focused emphasis on information programs of COSATI and OST.

2. COSATI being reorganized into eight panels: Operations Techniques and Systems, Information Sciences Technology, Education and Training (already in existence). Under consideration are: International Activities, Information Generation, Information Users, External Relationships, and Budget and Statistics.

3. Size of Federal information program not easily determined because of difficulties in distinguishing between information activities and the research or engineering activities of which they are a part.

4. Rough budget estimates for information programs of executive branch agencies for fiscal year 1966 totaling $380 million discussed. Does not include public relations activities, nor actual experimental procedures, laboratory work, hardware costs, or procurement of items. Also publication not dealing with science and technology is not included.

5. NSF will support an estimated total of $18.4 million, or 4.5 percent of the $380 million total in fiscal year 1966, as shown in comparative functional breakdown.

6. COSATI's main functions have been to (*a*) identify multiagency problems; (*b*) develop an interagency consensus on amelioration or solution of problems, and (*c*) exchange information among Federal agencies.

7. Agency actions to improve information systems: (*a*) payment of "page charge" policy; (*b*) standardization of "microfiche" for technical reports; (*c*) uniform identification method for Federal reports; (*d*) subject category list for announcement of reports.

8. New central organizations set up with special functions: (*a*) Clearinghouse for Federal Scientific and Technical Information (Department of Commerce); (*b*) Science Information Exchange (NSF and Smithsonian); (*c*) National Referral Center for Science and Technology (NSF through Library of Congress); (*d*) National Standard Reference Data System (Department of Commerce).

9. Interdepartmental COSATI task group working on top-level effort to develop framework for improvement of complex of scientific and technical information activities:

a. Congressional committees assisting have been House Committee on Science and Astronautics, House Select Committee on Government Research, Ad Hoc Subcommittee of House Committee on Education and Labor, and Subcommittee on Government Reorganization of Senate Committee on Government Operations.

b. Task group has held special meetings with non-Federal organizations.

c. Efforts focused on formalized document-handling communication mechanisms.

d. Study team from System Development Corp. assisting.

e. Anticipate a report by fall 1965.

f. Approach has been to divide information systems into (1) complex of library systems and (2) complex of information evaluation and retrieval systems. Tentative courses of action in each component suggested.

10. Problems to be resolved:

a. Congressional decision will be needed about which parts of information network are Federal-responsibilities and which should belong to private enterprise.

b. Cost-controlling mechanisms.

c. Skilled manpower to man the information network.

d. Adequate information facilities on college and university campuses.

e. Most important, creation of a permanent mechanism for insuring optimum management of components of national information network. Several possibilities mentioned: (1) COMSAT-like corporation actually operating information network; (2) new Federal agency to handle all Government information functions; (3) new Federal agency for top-level planning and evaluation functions; (4) assignment of top-level planning and evaluation to an existing agency; or (5) continuation of present organization.

B. Highlights of questioning

1. On relationship of NSF to entire information problem, see agency as having responsibility in accordance with its mission—the support of basic research and education in sciences and engineering.

2. On question whether NSF should not have a more important rather than lesser role in the future, said NSF will be a serious candidate for task of top-level planning and coordination of the complex of information systems.

3. Question why in reorganization of 1962 NSF was not left with coordinating responsibility for information not fully answered.

July 28, 1965

Witness: Dr. Thomas F. Bates, Science Adviser, Department of the Interior.

A. Highlights of statement

1. Research role of Department of the Interior:

a. Interior's research relates to its primary mission as technical consultant and trustee of Nation's natural resources.

b. Federal R. & D. expenditures for natural resources program believed to be inadequate both to carry out responsibilities and in comparison with other Federal programs.

c. Interior's research programs diversified in kind, character and amount. It varies among bureaus, with some relying on in-house work while others rely more on extramural research.

d. Details of Interior's present and future research programs, including key issues, were presented in 1964 letter from Secretary Udall, and covered water resources, energy resources, minerals and geology, land resources, fish and wildlife resources, and ocean resources and ocean engineering.

e. Key issues identified were (1) strengthening and increasing Interior's extramural research effort with universities and industry; (2) establishment of information centers for resource fields; (3) need for analytical groups in resource fields to study resource analysis methodology, ascertain resource needs, and formulate national plans; (4) additional ecological surveys and research; (5) acquiring operational ability for ocean resources research.

2. NSF-Interior relationships:

a. Association varies, e.g., very little contact with Bureau of Land Management or Bureau of Outdoor Recreation; multiple contacts with Bureau of Commercial Fisheries, U.S. Geological Survey, Office of Saline Water.

b. NSF and Interior share mutual interests in life, physical and engineering sciences; also in (1) reciprocal use of NSF and Interior scientists on advisory panels; (2) Interior's utilization of NSF facilities, such as oceanographic vessels; (3) use of data collected and collated by NSF; (4) membership on interagency coordinating committees; (5) Interior's participation in NSF national research programs; and (6) attendance of Interior scientists at NSF-sponsored summer institutes and a limited use of Interior laboratories by NSF fellows.

c. Problem areas: (1) Lack of communications between Interior, NSF, and the universities; (2) lack of sufficient research support by NSF for areas of major concern to Interior; (3) NSF fellowship and traineeship programs attract best students from

Interior's research, and (4) lack of NSF management policy to assure adequate coverage of all science areas.

d. Suggestions for improvements included (1) establishing NSF-Interior coordination and planning groups for mutual problems; (2) setting up NSF-Interior-university committees to identify gaps and imbalances and seek ways to rectify situations; (3) increasing use of Interior scientists on NSF review and advisory panels; (4) attracting students to Interior's areas of research concern through (*a*) cooperative programs whereby NSF-supported students use Interior's laboratories and equipment, and (*b*) increase in traineeships allocated in areas of "environmental" and applied sciences.

B. Highlights of questioning

1. Formal and informal relationships needed to improve communications between NSF, Interior and universities. Limited funds and specific missions have contributed to difficulties, as has insufficient cooperative effort.
2. Supported increased NSF involvement in research of interest to Interior's mission; e.g., support of students at geology field camps, use of Interior laboratories and facilities by NSF supported students.
3. Research needs should be met in a logical, planned manner rather than allowing the direction of research to be determined by submission of proposals.
4. "Engineering sciences" cannot be precisely defined, in terms of "fundamental science" and "applied engineering." Agreed on importance of guidelines to redefine "engineering sciences."
5. Research constitutes a major part of Interior's R. & D. expenditures; will supply figures.
6. Congressman Brown suggested that expansion of research funds for mission-oriented agencies plus greater interagency coordination and integration might be preferable to expansion of NSF.
7. Although private funding for earth sciences is important in total support picture, it is largely for applied rather than basic research.

July 29, 1965

Witness: Dr. Arnold B. Grobman, Director, Biological Sciences Curriculum Study.

A. Highlights of statement

1. NSF and scientific education. NSF has significantly improved science education through support of curriculum study groups; but much remains to be done.

2. BSCS group programs:

a. "Debilitating" deletions from content of NSF texts because of content determination by the nonacademic marketplace contrary to majority of informed opinion.

b. Principal contribution of recent curriculum study groups has been opportunity for scholars and teachers of a discipline cooperatively to decide course content. Because of NSF support the materials are free of nonacademic pressure.

c. Have been able to get publisher contractual clause proscribing any changes. Biological sciences curriculum study (BSCS) books widely accepted.

d. BSCS work financed by NSF grants totaling $8 million over 7-year period. Have earned over $1 million from sales and royalties. BSCS summarized.

e. NSF contributions include (1) initial support for the idea; (2) arranging for scholars and leaders in various disciplines to become acquainted with each other's work; (3) sympathetic funding; (4) suggestions for improvement from NSF personnel.

3. Difficulties in BSCS relationships with NSF:

a. In absence of policy guidelines prolonged NSF indecision has adversely affected program.

b. Grants awarded for short and variable periods making well-organized planning difficult.

c. Delay until last possible moment in awarding grants.

d. Improper interference in internal operations by NSF officials.

e. Adverse decisions on grant proposals without opportunity for discussion between reviewers and BSCS.

f. National Science Board has not taken full advantage of experiences of NSF grantees.

g. Undue policy control exercised through fiscal controls.

B. Highlights of questioning

1. Influence of nonacademic marketplace agreed to affect teaching more in areas where controversy possible, e.g., less in mathematics and physics and more in biology, social sciences.

2. Re summer institutes, most important weakness is that many of those who instruct the teachers are not interested in changing their methods. Other problem is the people who need the institutes most do not or cannot attend.

3. Too early to observe more than beginnings of "wave effect."

4. Too much standardization is avoided by producing different versions, each of which allows choice and by encouraging use of any materials teachers want.

5. Objective is to prepare model materials. When other materials become equally good, BSCS will cease operations.

6. Examples of problems: NSF refusal to fund revision in 1965 of books written in 1963. Arguments over copyrights.

7. O. of E. and NSF roles. NSF began curriculum revision support first. Both now support curriculum projects, but in different fields.

8. Re questions of NSF general support of education via curriculum improvement, and examination of basic structure of elementary and secondary education, commented on need for better science courses and for widespread curriculum studies, with latter under more representative body than NSF.

9. NSF should increase its involvement in curriculum development "until there is some other way of handling this problem."

10. Alternative sources of support are private foundations or O. of E. "I suppose on balance, the best home would be the Office of Education, but I am not enthusiastic about it."

11. No other curriculum program of NSF has been as extensive as BSCS. Methods of NSF support are similar to BSCS.

12. Responsibility for curriculum of each subject as taught rests with local school boards. Federal attempts at guidance would be deemed Federal control.

13. Use of BSCS materials nationwide—slow in South, in New England, and New York.

14. Expect three-fourths of the schools to use BSCS materials by 1968.

15. Funds spent on comparable textbooks by commercial enterprise negligible compared to BSCS program.

16. For BSCS to operate as continuing organization, would require about $800,000. On alternative sources of funding BSCS has not requested funds from NIH; asked O. of E. for one grant but have not received it. Policy committee decided not to ask mission-oriented agencies for money.

17. Believes general curricula recommendations could come more properly from a Presidential adviser on education rather than from O. of E.

18. BSCS materials cannot be translated for use in other countries unless adapted in particular country. Adaptation committees have been established in a large number of countries. Philippine book off press, supported by AID, foundations, and NSF. Funding is major problem.

19. BSCS "as a group rather cool" toward audiovisual devices. Prefer to concentrate on materials so that student working in laboratory can learn by discovering for himself.

August 3, 1965

Witness: Dr. Jerome B. Wiesner, Dean of Science, Massachusetts Institute of Technology.

A. Highlights of statement

Made general observations on research in our society, and the role of NSF. Commented on important and pertinent testimony of previous witnesses.

1. Research and society:

a. Recent discussions, in which subcommittee has taken lead, have clarified thinking on various roles of science and technology, applied science and engineering.

b. National motivation for spending for basic research based on realization that basic research is investment in continued national well-being and progress.

c. General social problems: (1) Proper level of effort, (2) proper balance among various possibilities, (3) who should make the decisions, (4) how should Government intervene, (5) dangers of Government intervention.

d. Proper level of R. & D. expenditure:

(1) Discussions with economists inconclusive; precise answer impossible. "Rule of thumb" for R. & D. expenditures: "* * * one should go on making increased research and development expenditures until the marginal increases in productivity in the society equal the increased expenditures."

(2) Difficulty: impossible to measure contribution of basic research to economic growth of our society.

(3) If assume productivity increasing 3 percent annually, get a $20 billion increase in GNP as result of R. & D. Could afford "very much larger" increases in R. & D. budget than have been making.

(4) Doubtful that annual 15 percent increase in R. & D. expenditures of past 15 years can be continued.

(5) "In the basic research areas, I think this is presently the Government's policy, the administration's policy, and I hope the Congress will support it, to see that basic research continues to grow at something like 15 percent a year. I am not convinced that even that is enough * * *."

2. Role of NSF within general framework:

a. Concur with majority of witnesses that NSF share of basic research support is probably too small.

b. Does not know what NSF share should be—"* * * shouldn't be 80 percent and * * * 14 percent is too low. I think one can start to let it grow, in fact I gather this is happening, and watch it and see where we think we have reached a healthy balance."

c. Would preserve multiple sources of basic research support (1) to preserve quality of mission-oriented activities, (2) to allow experimentation, and (3) to preserve competition.

d. Geographic distribution one of most serious problems of NSF and the Government: Involves reconciliation between economic well-being of geographic areas, and agency mission demands to find the best competence wherever it exists and to support most promising persons where they are found. Useful to "push * * * very hard" programs to increase number of first rate teaching institutions.

e. Slow growth of NSF has been criticized. Timidity of Board and lack of aggressiveness of management may be partly responsible. Main reason is lack of strong Executive and congressional support because NSF lacked mission-oriented functions until it became involved in science education.

f. Increasing control, redtape, and bureauracy in NSF and other agencies criticized. Suggested examination to see whether bureaucratic trend can be reversed without relinquishing executive and legislative responsibilities. Part of problem is that Government fiscal practices necessitate frequent applications for support, wasting time and effort.

g. Fifteen-percent annual increase for basic research a composite of (1) natural rate of growth of science; (2) rate of educational process; (3) increasing salary scale of scientists and engineers, estimated at 5 percent per year; (4) increasing costs of apparatus. No alternative to this rate of increase if accept criterior to support "good basic research activities."

h. Inadequate support of engineering in general, and engineering research by NSF. Scientific and engineering community at fault in failure to recognize opportunities. Increased engineering research could solve major problems not likely to be undertaken privately and would train students in these fields.

i. Agreed NSF educational activities and new curricula development should be increased.

j. NSF and other federal funding inadequate for behavioral sciences, including communication sciences, economics, and social sciences.

k. Use of computers in science and engineering education has created a crisis in American universities:

(1) Must provide more computers on campus.

(2) Must support academic use of computers—uncertain whether NSF or O. of E. should do.

l. Agreed that some sciences are undersupported or underequipped.

m. Problems of small schools in teaching science need increased NSF assistance with curriculum development and possibly support of science faculties.

n. Government Science Corps suggested as source of teachers for small institutions, also assistants in Government laboratories, science attachés abroad, and part-time work in the larger universities and in industry to stay current.

o. Agreed NSF should increase international science activities, particularly cooperative projects.

B. Highlights of questioning

1. Despite multiplicity of Federal research activity, NSF can assume a larger role if a dominant position in policy and support of basic research is made clear through support for the fields of science for which it is responsible.

2. Concerning NSF organization—

a. Staff should be increased for some activities, e.g., educational R. & D. and in curriculum development.

b. Certain policy issues will have to be solved, e.g., how to support large scientific projects such as Mohole.

c. Director should be stronger vis-a-vis the Board. Although not recommended in Reorganization Act, consideration given to making Board a policy adviser and giving operating responsibilities directly to Director. Concept still worth consideration.

d. Negative reaction to suggestion for full-time Chairman of Board.

e. Any full-time staff for Board should be carefully limited in responsibilities.

3. Major overhaul of organization not needed. Board and Foundation staff have been reviewed, and Board has changed its structure.

4. Dr. Wolfle's suggestions for improvement of NSF's statistical functions "ought to be taken every seriously." Important for both NSF and OST, and other agencies.

5. Difficulties in support of behavioral sciences due partly to interpretation of "science," fear of criticism of work that suggests manipulation of public opinion, and uncertainty among behavioral scientists concerning their needs.

6. Did not believe that NSF should recapture coordinating functions now in OST.

7. Computer problem is "several times the scope of the Science Foundation's ability to deal with."

8. The 15 percent increase will not attract too much scientific manpower into basic research.

9. No opinion about balance between NSF support for basic research and science education. Balance satisfactory except insufficient support of educational R. & D. while he headed OST.

10. Impatient with rate of growth of NSF which has not yet compensated for the slow growth during first decade.

11. NSF international science role could include leadership in education abroad. Other agencies such as AID should have interests.

12. NSF mechanisms are "really fairly good" for allocation of funds among various fields.

13. Primary function of NSF should remain the support and stimulation of basic research and quality scientific education.

14. Supplied for record views on combining OST and NSB and the Foundation to coordinate scientific research of Federal Government.

15. Not necessary to amend National Science Foundation Act to strengthen activity in certain areas.

16. Board authority sufficient to go directly to President or to Congress in opposition to the NSF.

17. Re roles of NSF, O. of E., and NIH. NIH has no legal responsibility or authority for education. NSF has looked to NIH to support health-related research and has concentrated its effort in other fields. NSF might not have developed its educational program if O. of E. had been more aggressive in science.

August 4, 1965

Panel Discussion on Scientific and Technical Manpower

A. Highlights of statements

Bryce Crawford, Dean, Graduate School, University of Minnesota

Sees research assistantships, teaching assistantships and nonservice appointment fellowships all important. Notes benefit of teaching experience. Ideal system would encourage any graduate student doing research to do some teaching with also an adequate amount of nonservice support to take an "undistracted slice of time" for his studies. Would not make teaching mandatory.

William A. Douglass, President, Careers, Inc.

If some 60,000 engineers and scientists apply to his concern for change in jobs in the last 2 or 3 years, there is something in need of discussion. Identifies as subjects needing attention: technical obsolescence, continuing education, mobility, proper use of skilled aliens.

James Killian, Chairman of the Corporation, MIT

Re supply and demand for scientists and engineers, shortages more likely to occur in science, engineering, medicine, and mathematics than in humanities, social science, and law. Summarizes Killian Report (NAS study): risk is having too few rather than too many students choose science and engineering; proportion of colleges committed to science and engineering not robbing humanities and other fields.

Adequate manpower information is a problem. Repeated recommendations for single agency or office with responsibility and authority for coordinating the various Federal efforts to provide adequate and continuing information on scientific and technical manpower. More interpretation and projections needed. NSF should be a partner in such a central effort.

NSF could have taken earlier initiative in aid to potential centers of excellence and "creating new innovative programs." These are needed now, take a long time to build. We are overdependent on a few centers today which cannot turn out enough high quality graduates without growing too big.

Identifies NSF teacher training and curricula development as "breakthrough" in improvement of education. Calls for more support.

Leonard A. Lecht, Director of the National Goals Project, National Planning Association

NPA studies of national goals anticipate total spending of $39 billion a year by 1975 (in 1962 dollars) for R. & D., an increase of almost 2.5 times from 1962 to 1975, with largest increase in the civilian economy area—health, transportation, air pollution, water, and small business. Forecasts 125 percent increase in number of scientists and engineers from 1960 to 1975, requiring an increase in manpower pool of 1.75 million between 1962 and 1975.

Calls for national priorities planning in Executive Office of the President to identify the scientific and engineering skills required for all major national activities—public and private. Demands previously balanced by the market, but large public programs have distorted balance and make Government action necessary.

More information needed. Why the relative decline in degrees in engineering—from 10 percent in 1958–59 to 7.5 percent in 1962–63: how convertible is technical manpower from defense and space to civilian use.

Foresees increasing need for trained and educated manpower. Improve supply by positive steps to develop and expand manpower research and planning.

Frederick Terman, Vice President, Stanford University

Re manpower shortage, thinks much concern misdirected toward numbers rather than quality. No real lack of warm bodies, but there is. and has been, continuing shortage of engineers and scientists with high training and ability. Too few students continue into graduate study. As a result, jobs often filled with people with less training than needed, which downgrades effectiveness of our industrial economy, causes overruns and failures, weakens our position in international competition in science and technology.

Notes actions to carry out PSAC recommendations: new training grant program of NSF, NASA trainee program, NDEA activity. But these not enough and fall below PSAC targets.

Financial support essential for graduate students. Thinks NSF educational spending distorted; would prefer to see money going to high school science program invested instead in support of graduate education in mathematics, physical sciences, and engineering.

M. H. Trytten, Office of Scientific Personnel, National Academy of Sciences

Notes need for more study in depth of manpower. NSF data collection so demanding that it has little opportunity for studies in depth about what the statistics mean. Favors Wolfle's proposal to establish a separate entity to determine the meaning and significance and relationship of the factual information being gather. Calls for future NSF support of the present privately financed Commission on Human Resources to do this.

Notes increased flow of students into graduate study because of various Government financial support but wonders about adequacy of information concerning the quality factor. Suggests some sort of post audit to qualify, perhaps via the graduate records examination.

Bowan C. Dees, National Science Foundation

Defends NSF statistical services in face of absolutely insatiable desire by users for more information. NSF has known what was needed, wanted to do it, but could not always get resources. Warns of bringing low quality students into the science education program and the need for a long term view.

B. Highlights of discussion period

1. *Undergraduate education.*—Killian thinks science preparation in precollege schools and improvement of curriculums at undergraduate level is of fundamental importance, and should not be delayed.

2. *Retraining.*—Needed by men 35 years of age and older. Notes most industrial education is for younger men, not older ones. Government will not pay costs of preemployment retraining of competent people for work on contract projects. Better fundamental science and engineering education seen as remedy to obsolescence. No Government responsibility to the individual for retraining; Government, however, should provide opportunities for better training to produce more versatile people, and to recognize problem of additional graduate study. Proposal for free public retraining from ages 35 to 38 to everyone who wishes it. Seconded by Douglass for a demonstration.

3. *Centers of excellence.*—Needed so that those with the greatest potential must be supported right now wherever they may be, with attention to geographic distribution later. More centers needed because there isn't enough capacity now in graduate schools for future requirements. Developing new centers takes a lot of effort over a long period. Need to upgrade other institutions to become potential centers. Warning against forced growth and premature furnishing of fellowship support.

4. *Two-year training.*—Too many people in 4-year college who should be in 2-year institution. Excellent 2-year men needed as well as excellent 6-year men.

5. *Single manpower agency.*—NAS recommendation recalled by Killian for central responsibility for stimulating and coordinating planning by Federal Government for scientific and engineering manpower, and developing integrated collection and analysis of information. No present place to initiate, instigate, and stir up. NSF had considered this before NAS report and a group has been set up to concern itself with science resources of the country generally, is beginning to make progress. President's Manpower Committee has Cabinet rank and responsibility to consider ways and means of setting up more centralized evaluation.

6. *Econometric models.*—Gross absence of adequate mathematical models of the economy. NSF trying to develop growth models in two areas: one at Ann Arbor and one still unassigned. Relationship of R. & D. and economic growth a very important level of research.

August 5, 1965

SEMINAR ON SCIENCE ON SMALL COLLEGES

A. Highlights of statements

1. Dr. Sanford Atwood, Emory University:

a. Small colleges valuable source of graduate students in sciences; act as "grassroots centers for the selection and training of scientifically superior students."

b. Eighty percent of Emory's B.A. and B.S. male graduates go on to graduate study.

c. Illustrates importance of NSF High School Institutes, NSF undergraduate research participation program, and teacher training activities.

d. Strongly endorses NSF programs, wants them expanded to develop competency of small colleges as well as large universities.

2. Dr. James P. Dixon, Antioch College:

a. Small liberal arts college seen as an important source for recruitment and pretraining in the disciplines of physical and social sciences.

b. NSF concentration on undergraduate support on preprofessional training may miss potential creative scientists who are pursuing general education at undergraduate level.

c. NSF failing to support education of citizen leaders equipped to "manage humane science policy."

d. Small college physical and social science faculties viewed as second class by universities because of limited research opportunities; extremely difficult to hold faculty of quality needed to train students for graduate study.

e. Proposes:

(1) Institutional grants to small colleges to develop undergraduate students and faculty.

(2) Teaching interns.

(3) Groupings or consortia of small colleges.

3. Dr. Katherine McBride, Bryn Mawr College:

a. Presents case study of variety of NSF programs in Bryn Mawr.

b. Looks to NSF to support basic research and graduate students. Cooperative fellowships and graduate traineeships very helpful.

c. Discusses NSF undergraduate research assistance and NSF institutional base grants.

4. John E. Sawyer, Williams College:

a. More capacity for Ph. D. training than there is supply of students. Small colleges a needed source.

b. Sustaining science in small colleges emphasized and also importance of liberal arts education to scientists.

c. Small colleges cited as source of science teachers.

d. Endorses emphasis on excellence and ability in selection among proposals.

e. Mentions five areas needing NSF support:

(1) Science buildings.

(2) Equipment and research assistance.

(3) Balancing teaching loads.

(4) Professional contact and development.

(5) Summer compensation.

5. Dr. Richard H. Sullivan, Reed College:

a. Praises NSF competence.

b. Stresses small colleges as source of science teachers.

c. Favors institutional and undergraduate support programs of NSF.

d. Calls for strengthening of faculties with NSF support through faculty programs and curricula development programs.

e. Favors undergraduate research participation.

f. Suggestions:

(1) NSF support to small colleges get more involved in information transfer by feeding scientific information through undergraduate faculties. NSF support for small college education of citizens in public issues of science.

(2) Establish central data bank for information of small college faculty seeking research support. Provide orientation for all Federal science support.

(3) Discretionary funds to colleges to support students that fellowship and traineeship support "may have overlooked," through reliance on impersonal indicators.

(4) Expand institutional support for centers of excellence.

B. Highlights of questioning

1. National Science Board:

(a) Meetings: Monthly meetings of NSF special committees provides extensive opportunity for discussion and exchange of opinion with NSF. (McBride)

(b) Full-time chairman opposed. (McBride)

(c) NSF staff: NSF staff found time to prepare materials and meet with Board. (McBride)

2. Fellowship limitations: Will cause loss of talent unless other support available. (Sullivan)

3. Undue dependence on NSF: NSF supports only 2 to 3 percent of small college budget versus 20 to 30 percent in large universities. No undue or inappropriate Federal influence. (Sawyer)

4. Consortia: Favored by Dixon; possibility of NSF support via contracts with consortia. Could be used to administer programs. (Dixon)

5. Disadvantages of matching requirements. (Sullivan)

6. Subprofessional training: Technical schools not in competition with small colleges. (Atwood)

7. Overhead: Smaller colleges can live with present limitations. (McBride and Sawyer)

8. Computers: Important to university research and training. (McBride) Training needed. (Sawyer)

9. Social and environmental science support: Research opportunities needed. (Dixon) Social sciences starved. (Sullivan) Restraints on social science in world affairs. (Brown)

10. NSF-university relations: Should be two way. Presently, colleges and universities go to Washington as supplicants; would have NSF actively seek to interest colleges and universities in its programs through regional offices. (Atwood) Field visits and regional conferences noted. (Sullivan)

11. Teacher training: The most rewarding of NSF's programs. (Atwood)

12. Starter grants for young faculty. (Atwood)

August 19, 1965

Witness: Dr. Leland Haworth, Director, National Science Foundation.

A. Highlights of concluding statement

1. Social science: NSF support increasing proportionately more rapidly than other programs; up 6.6 times since 1960.

2. Fellowships in engineering: Ratio of successful applications for engineering fellowship to total applications very close to ratio for applications in sciences. Gives details and growth trends. Text of statement on graduate education in engineering.

3. Royalties on texts: Actual royalties received for BSCS about one-half million dollars. Additional public benefit is printing of extra copies of preliminary books at cost for use by nonparticipants. Total royalties for all texts about $2 million with another million in escrow.

B. Highlights of questioning

1. Student support: Defined and discussed graduate fellowships, traineeships and cooperative fellowships. Plan to drop cooperative fellowships, if National Science Board concurs, and shift this support into the regular fellowship and traineeship programs.

2. Authorizing legislation: Haworth has no opinion on benefits of authorizing legislation. Endorses interchange of information between executive and congressional committees. Tells of experience with Joint Committee on Atomic Energy probing in depth into some phases of AEC program each year. These were unquestionably of great value to the Commission. Penetrating hearings in depth on the various aspects of an agency's programs are a good thing.

3. National Science Board: Opposes separate staff, would prefer to see present staff given more time to assist Board. Advisory role considered, Haworth has no strong feeling pro or con. Notes problems of daily decisions relieved by delegation of operating authority from Board to Director. Thinks academic community prefers present role of Board.

(Text of W. W. Houston's letter about Board.)

4. NSF self-examination stimulated by hearings. Regular self-examination through NSF Planning Council and NSF Associate Director for Planning. Notes science development program a product of this planning. Presently considering long-range role in science education.

5. Scope of NSF Charter: "* * * the broad charter that the Foundation has has been a very fine thing, * * * would hate to see it restricted in any sense."

6. Balance function: Self-examination caused by hearings has led to change in view of balance wheel idea from hole plugging to desire that NSF be in the forefront in taking account of the capabilities and sup-

port of other agencies in meeting its responsibilities for scientific health of the country.

7. Mohole and applied research: Justifies large-scale engineering for project Mohole because basic research is its final purpose. Would not be appropriate for NSF to go into engineering development except as means to end of doing basic research. "This is, to my mind, one of the reasons that we have to be cautious about thinking about getting into applied research."

8. Mohole project: Haworth stresses mantle penetration is only one of many assignments for Mohole facility and that whole cost should not be charged against the mantle project. Says present estimate to get facilities into being is $75 to $80 million. Analogy with Brookhaven and Berkeley accelerators.

9. Big science: NSF has basic research role in big science. Notes fear that big science competes with academic research for funds, but thinks NSF must support its share of big projects. Re NSF future support for big science, can answer this better when all NAS reports are in. Mentions astronomy and computers. Note question of Mr. Vivian about specific big projects.

10. Growth trend for basic research: Allocation of the 15-percent increase recommended for academic research would be determined largely by activity of various fields of science in submitting proposals. Expects biochemistry to be active. Sees self-governing mechanism. Notes NSF can and does recognize areas not being supported and seeks to attract attention and proposals.

11. International science: Four areas of NSF participation:

a. International cooperative ventures; e.g., IGY, etc.

b. Procurement of special research capability available only abroad.

c. Support of science and science education in developing countries as foreign policy objective.

d. Grey area where for foreign policy reasons it may be desirable to support foreign science even though capability exists here.

12. Reorganization Plan No. 5: Haworth has not yet crystallized plans to delegate his authority to staff. Mentions delegations to his Deputy Director. Authority delegated to Director by NSB seems redelegable.

APPENDIX 2

RESPONSE BY WITNESSES TO QUESTIONS SUBSEQUENTLY SUBMITTED BY THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

RESPONSE BY DR. LELAND J. HAWORTH, DIRECTOR, NATIONAL SCIENCE FOUNDATION, TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

NATIONAL SCIENCE FOUNDATION,
OFFICE OF THE DIRECTOR,
Washington, D.C., August 16, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research and Development, Committee on Science and Astronautics, House of Representatives, Washington, D.C.

DEAR MR. DADDARIO: Please find attached my responses to the questions that you sent me on July 17. Extra copies are included for you to provide your subcommittee members and staff.

I am sorry that I was not able to complete my answer to question A-3 regarding any possible role of the Foundation in applied research in time to include it with this transmittal. Question A-4, the answer to which is dependent on that to A-3, has also been omitted. I hope to have these responses available by the time I testify on Thursday, August 19.*

In preparing my replies, the Foundation staff and I have, of course, been influenced by our knowledge of past actions taken and points of view expressed by the National Science Board. However, I should make it clear that the opinions are my own and do not necessarily represent the views of the Board. Indeed, except for a few fragmentary conversations with a very few individual members, I have not been able to discuss the questions with the Board.

I shall be happy to provide additional comments on any of the questions if you so desire.

Sincerely yours,

LELAND J. HAWORTH, *Director.*

*This material, subsequently provided, is included on p. 914.

CONTENTS OF RESPONSE BY DR. LELAND J. HAWORTH

A. General Policy and Authority

A-1. In the light of your participation in the committee hearings, would you please review for the record what you consider the National Science Foundation's basic role is or should be in formulating, coordinating, or evaluating national science policy?

"National science policy" is a constellation of interrelated policies. These policies may be grouped together under this singular term because they affect, directly or indirectly, the level, substance, and conduct of scientific activities in the United States, the opportunities for and content of education in the sciences, and the utilization and development of the Nation's resources for science. Science policies are also shaped by State and local governments and by nongovernmental institutions, enterprises, and organizations. It is appropriate, therefore, to speak of a constellation of both public and private science policies.

I make this point because I believe that the Foundation has a role to play not only in connection with the science policies of the Federal Government but also with those of non-Federal public and private sectors of the Nation. The scope of the Foundation's role is dictated by its statutory responsibility "to develop and encourage the pursuit of a national policy for the promotion of basic research and education in the sciences." The Foundation's overriding concern is to assure the progress of scientific knowledge and the strengthening of the manpower and institutional capabilities for science in the United States through policies and programs directed toward basic research and education in the sciences. But this concern does not rest with the Foundation alone. It is one which the Foundation shares with other Federal agencies, levels of government, and organizations and institutions in the private sector.

The Foundation's own policies and programs are designed to maintain and enhance the health and vigor of basic research, and to expand the opportunities for education of high quality in the sciences. It is our hope and belief that NSF can assist, through these efforts in strengthening the scientific and educational capabilities of academic institutions. I believe that what NSF does directly through its own operations it should complement by an active leadership role in developing, evaluating, and proposing alternative policies by which the Federal Government as a whole, the State and local governments, and private institutions and organizations could contribute to the realization of these primary objectives. This in my view is a basic and continuing Foundation role. It should and can be fulfilled in several ways.

One is by providing improved essential information about the Nation's resources for science and their development and utilization. Another is by undertaking analytical studies of the dynamic, diversi-

fied system by which research and education in the sciences are supported. A third is by conducting or arranging for the conduct of investigations dealing with the resources required to capitalize on science and to guard against the neglect of any one field or subfield in the sciences. Still another is by designing, and where possible testing, experimental programs of a pioneering and innovating character with respect to research and education in the sciences.

In short, the Foundation should, in terms of the Nation's overall stake in science, play a vital part in developing an understanding of the possible courses of policy action open to it. NSF should lay the basis for, and point the way toward, policy recommendations of a broad, overall character.

On the coordination of national science policy, where specific responsibilities fall to OST, FCST, and BOB, the Foundation has a basic role to fulfill. This, too, takes several forms. The Foundation should continue—and where possible strengthen—its formal and informal cooperative relationships with governmental agencies, academic institutions, and concerned voluntary organizations and professional societies. It should continue to contribute to, and help strengthen, the coordinating functions performed by OST, FCST, BOB, interagency committees, and PSAC through the provision of essential data, staff assistance, and analytical studies on significant policy problems and issues. Finally, it should undertake to initiate and propose policy guidelines in the Nation's total effort to upgrade its research and education in the sciences.

With the Reorganization Act of 1962, the responsibility for evaluating the scientific and technological policies and programs of Federal agencies was assigned to OST. In this area, consequently, NSF's role must be defined as a contributory one. This role is expressed in its responsibilities for providing: information on the funding of research and development and knowledge about the Nation's resources and requirements of manpower and institutions for science; assessments of the probable consequences of existing policies for these resources; and suggestions for improvements.

A-2. To what extent is the Foundation limited in functioning as an operating agency? Why? Should it be given greater operational authority?

The Foundation's operating authority is limited by section 15(c) of the National Science Foundation Act of 1950, as amended, which states:

> The Foundation shall not, itself, operate any laboratories or pilot plants.

This restriction extends only to Foundation operation of laboratories or pilot plants with the aid of Federal personnel. Since any operations which the Foundation might desire to have carried on can be accomplished satisfactorily through the grant or contract mechanism, we see no particular need for greater operational authority. Our experience with the national laboratories (and analogous experience by the Atomic Energy Commission) demonstrates the feasibility of meeting operational requirements through contract arrangements.

A-3. Should the National Science Foundation be given added authority to concern itself with applied science? If so, to what extent?

A-4. Should any added authority along the lines of A-2 or A-3 be made a directive—or merely permissive?

The National Science Foundation, in the national interest, must consider means to foster the overall development of science, including education, in academic institutions. While the role of applied research enters into this consideration in many disciplines, it arises with particular urgency with respect to engineering and the social sciences.

Many people today believe that more applied research at engineering schools is necessary to develop the type of engineers needed to adapt new scientific knowledge to engineering applications for the welfare of the country. Limiting support for research to that which is purely basic interferes with the ability of these schools to enrich their theoretical curriculums with more applied research opportunities. Similar considerations apply in certain of the social sciences.

Moreover, it is the nature of scientific research that findings may be unexpected. It is important, therefore, for an investigator to be able to follow promising leads developed in the course of a basic research project even though this takes him into applied science. In this way, totally new and fruitful frontiers in basic science and applications of great value to the country may become evident.

I think, therefore, that in the national interest it is important that the Foundation more broadly support research at educational institutions, both to assure better training for young scientists and engineers and, also, so that worthwhile research which scientists and engineers at academic institutions wish to pursue may be undertaken on a broad spectrum.

In an effort to define basic research in the engineering sciences so as to best meet these needs of science and engineering within the original intent of Congress as expressed in the NSF Act of 1950, the National Science Board, in 1962, resolved that:

> * * * the National Science Board considers that intellectual pursuits at educational institutions intended to advance significantly the basic engineering capabilities of the country are eligible for support by the National Science Foundation as basic research in the engineering sciences. Such work must be of a true scientific nature and not routine engineering practice, and must meet the usual NSF standards of originality and excellence.

While this clearly covers substantial parts of the research which should be supported in the field of engineering, it does pose many problems of application to particular situations which lie in a gray area of permissibility. Furthermore, similar problems are increasingly arising in supporting research in the social sciences, as the Foundation's programs in this area grow.

I have discussed this situation with the Executive Office of the President and it was agreed that these problems connected with the broad support of research at educational institutions warrant serious consideration within the next few months in the light of the Foundation's responsibilities for improving the caliber of educational institutions. In any event any legislation in this area should be permissive and not mandatory. I would like to stress further that even if the NSF Act were amended to permit support of applied research in academic institutions, I am confident that the Foundation will continue to regard

its primary research mission as the support of basic scientific investigations.

Apart from the particular considerations involved in the support of applied research at educational institutions, opportunities which need to be pursued in the national interest outside academic institutions will arise in areas of applied research where adequate support is not available. Industry may fail to initiate or support such research, for example, because of the expense involved coupled with the remote likelihood of the results of the research being of benefit to any single company. Government may fail to support the research because it does not fall clearly enough within the mission of any particular agency. However, this area needs much more consideration. As a first step in this consideration, the Foundation is contemplating sponsoring studies to examine the contribution which augmented and organized applied research might make toward solving some of the pressing social problems, how such efforts might be marshaled and what role various agencies of the Federal Goverment might play in them.

A-5. Should NSF assume a more active role in the support of international science programs? In basic research only? In applied research? In scientific development? Might not U.S. aims, other than the development of pure science, be furthered thereby?

Several witnesses have testified in this series of hearings to the effect that the United States should be playing a more dynamic role in using science as a means of furthering our foreign policy objectives, and that our own domestic programs in science and science education would benefit from a larger number of cooperative scientific ventures. I believe that both of these points are well taken. With respect to the role of NSF in creating a more satisfactory situation in this regard, it would be necessary to provide both broader authority and increased appropriations if NSF were to add new responsibilities beyond its present scope, which is primarily limited to support of domestic activities.

NSF has never been heavily engaged in the support of international scientific activities, but almost since its inception there have been elements of its efforts which have involved it in international matters to a degree. NSF has, of course, participated very actively in a number of international cooperative science programs, such as the Antarctic research program, the International Year of the Quiet Sun, and the International Indian Ocean Expedition. These are programs in which each participating nation has funded its own work. In this response to question A-5, we will mainly deal with other kinds of international science programs.

NSF has had enough experience to be able to foresee some of the challenges that lie ahead. To some extent, with no change in its present mandate, the Foundation will find it desirable and at times necessary to further extend its international role; it may be helpful to review some of these activities in order to gain perspective.

With regard to basic research abroad, NSF could assume a more active role; but an increase in such support raises two issues. First, the Foundation now funds only about two-thirds of the meritorious domestic research proposals submitted, and the allocation of funds for support of research abroad might be questioned by U.S. scientists

and the Congress. Second, the gold outflow problem is involved. In fiscal year 1965 NSF was limited to $700,000 for support of research in certain foreign countries; the Foundation spent about $637,000 in *all* foreign countries.

The Federal Council for Science and Technology has requested all agencies to examine their support of research abroad and to support only those projects within the agency mission which will contribute to science in the United States. Other agencies of the Federal Government, including the Department of Defense, support mission-oriented research abroad, some of which is of such a nature that it could also be supported by the NSF. The President's Science Advisory Committee has suggested that our foreign relations would be better served, at least in some countries, if research support were given by a civilian rather than a military agency.

One way of increasing NSF research support abroad which would not involve a large increase in direct grants to foreign institutions would be to encourage more cooperative programs between American and foreign universities. The foreign university would be expected to contribute significant funds to the project, NSF funds going only to the American university. Programs of this sort not only tend to increase support of research in foreign universities by the government involved, but also enable outstanding scientists in the two countries to work more closely together. Science everywhere profits from such endeavors.

NSF could also play a more active role in science education. Developments in science and science education in any country are of universal interest. This has been demonstrated by the interest aroused abroad by the new developments in science education in the United States. For example, the new course content materials may turn out to be one of America's most valuable exports. At least 40 countries are now using these materials, or modifications of them, in their school systems; and many texts and laboratory manuals have been translated into other languages. Some scientifically sophisticated countries are finding these course materials of great interest. The United States could profit if there were even greater cooperation than now exists between American scientists and their foreign colleagues in this field.

NSF could also increase its activities with international and regional organizations which have scientific programs of importance. At present there is no central point in Government which has the responsibility for U.S. participation in and "backstopping" for their science programs. NSF could make a significant contribution if it were assigned such responsibilities.

The question of a more active NSF role in the support of international science programs in applied research is, of course, dependent upon whether NSF's domestic program is expanded to include more applied research. In any event, however, I do not believe that NSF should become involved in the support of applied research abroad in the near future.

NSF hopes to be able to work more closely with AID to help improve science education, scientific research, science in general, and to a certain extent, technology in the developing countries. In this area

the Foundation could also work much more closely with multilateral agencies (such as UNESCO) which have relevant responsibilities.

Through two agreements with AID, NSF now has programs designed to help improve science education at the secondary level in all of Latin America and in higher education in the five Republics of Central America. Experience in Latin America suggests that NSF has a most unusual opportunity to help developing countries adopt modern methods in the teaching of science. Under present law this can be done only with money supplied by AID. Discussions with AID staff, in Washington and abroad, suggest that requests will be made for NSF advice and help in science education in several developing countries. NSF will respond as fully as it can to any such requests.

One important area in international science closely related to science development is now being neglected. NSF, with congressional approval and a modest appropriation, could make a positive contribution. This is in the so-called gray area—which may be defined as the support of scientific activities abroad where foreign policy considerations are at least as important as scientific ones. There are many good scientists in developing countries whose research is hampered by lack of equipment or research assistants. In many of these cases a modest grant would pay dividends in terms of research results and international amity. For example, many foreign scientists do graduate or postgraduate work in the United States. Hundreds of them do not return to their countries because of the lack of opportunity to do research there. A program designed to give properly qualified foreign scientists a modest grant would encourage these able people to go back to their own countries and develop scientific research and education centers which their countries need.

A-6. The charts you presented at the hearings included a graph on trends in Federal obligations for scientific research (chart No. 8) and a bar diagram on the total NSF program by research areas (No. 13). Do you see a need for any change in the modest Government participation in social science research? Should NSF concern itself with the social or behavioral sciences; or should its role, in your judgment, be confined to support of the natural or physical sciences?

> *C-5. In view of your statement that the Foundation's role in the promotion of basic research should be a more active one, how has the Foundation currently defined its role for the support of research in the social sciences? What is the scope of coverage in this area and the subareas supported, and what are the plans of the Foundation for future support of the social sciences in relation to other fields?*

Government participation in social science research should increase, and NSF should play a significant role in that increase.

NSF programs in this area have now reached a stage where further expansion is warranted. The attached chart provides data on the relative increase in support for the social sciences as well as the other sciences supported by NSF. NSF support of research in the social sciences has been limited to support of that element of investigation in these fields which can be designated *scientific*; this means that the major area which has been excluded from eligibility for support by

NSF is "policy-oriented research." This is consistent with the NSF role as an agency concerned with the promotion of science.

NSF should not be confined to the support of the natural or physical sciences. It is not now so confined. Experience has shown that the social sciences have many areas of overlapping interest with the natural sciences and profit by association with them. Subjects and techniques of investigation vary among the many different sciences, but the spirit of objective, analytical inquiry is common to all. Moreover, the social sciences are regularly established parts of the academic scientific enterprise, and as NSF assumes responsibility for the health and growth of college and university-based research and training in the sciences generally it should respond in a way which conforms to the patterns chosen by the academic community at large with as few artificial boundaries as possible.

The basic research and related activities which the Foundation currently supports in the social sciences include scientific archeology, social and physical anthropology, economic and social geography, demography, economics, the history and philosophy of science, linguistics, political science, psychology, and sociology. Within these broad disciplines the Foundation strives to support activities that are scientific in method. The proportion of research in social science subjects that is objective, independently verifiable, and subject to useful generalization has been growing in recent years. Indeed, we believe that the support afforded by the Foundation has been a factor in accelerating this important advance. The role of the Foundation, therefore, is to further encourage the development of scientific methodology in the social sciences and provide adequate support for scholarly research and studies—especially in the academic setting.

The Foundation's involvement with the social sciences has been a gradual development over the past decade. The pattern of seeking NSF support for basic studies, while well established in the natural sciences, is just beginning to emerge in the social sciences. For this reason the scope of the Foundation's interest in the social sciences is not completely known to the academic community, and as a result the Foundation is not yet fully aware of all of the important needs in the social sciences as a whole or in the separate disciplines. We, therefore, cannot confidently assess the degree to which the Foundation is currently meeting such needs.

The pattern of Foundation support in the social sciences in fiscal year 1964 appears in the following table:

Grants for basic research in the social sciences, fiscal year 1964

Subfield	Number of grants	Total amount
Anthropological sciences [1]	108	$2,699,305
Economic sciences [2]	48	2,207,164
Sociological sciences [3]	60	2,620,307
History and philosophy of science	36	572,800
Special projects and resources	9	1,278,600
Total	261	9,378,176

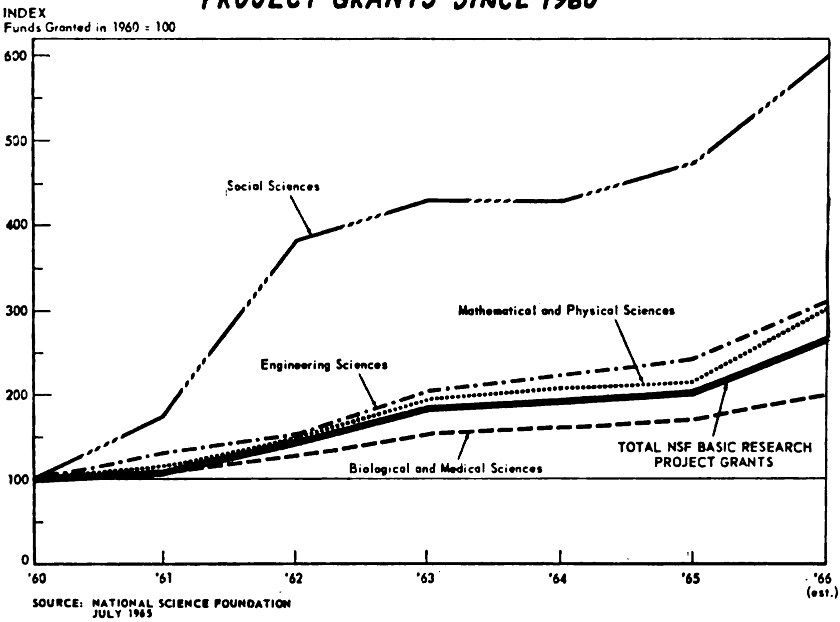
[1] Includes archeology, social, cultural, and physical anthropology, and linguistics.
[2] In addition to economics, economic and social geography is included.
[3] Includes sociology, social psychology, political science, and demography.

The future level of Foundation support for research in the social sciences will be dependent upon a number of factors. Among these are:

1. Total funds available to the Foundation.
2. The intellectual quality of proposed research.
3. The importance of the research relative to its impact on education, the social sciences, and other sciences.
4. The levels of support available to these disciplines from other sources.

NATIONAL SCIENCE FOUNDATION

RELATIVE INCREASE IN BASIC RESEARCH PROJECT GRANTS SINCE 1960



A-7. In your concluding remarks on June 25, with reference to the NSF Act, you stated:

> ***As we survey the past policies and procedures of the Foundation, however, we recognize several areas in which there exists authorization over and above that which we have fully utilized heretofore. I believe that we can use these additional elements of our authority in ways which are beneficial to the Nation.***

Specifically, what sections of the NSF Act have not been "fully utilized heretofore," and how do you plan to utilize them in the future?

In my earlier remarks quoted in this question I did not say or intend to imply that there were whole sections of the NSF Act which have not been utilized. I had intended to say that, because our mandate is a broad one, there are other things that we can do under it that we have not yet done. Let me give a few examples of the kind of thing I had in mind.

The science development program that we initiated last year is beginning to have a significant impact in the institutions that might be

designated as "fast-rising universities." But there are many institutions of higher education—both 4-year colleges and struggling universities—which need a kind of assistance, a type of financial boost, which is based on criteria different from those used in evaluating science development plan proposals. Thus we need to work hard—and we are doing so—to develop ideas, plans, and programs to help institutions in this category. I like to refer to the still undescribed program we are trying to invent as a "junior science development program." The relevance to the question in this case is: we have the authority to do virtually anything that would help institutions in the category I have mentioned to develop their capabilities for educating students in science or for doing research—but we do not have a specific program directed especially toward helping them solve, institutionally, some of their problems. This is a prime example of where we have and hope to use authorization "over and above that which we have fully utilized heretofore."

We are currently trying to develop a new approach to the matter of assuring substantial, up-to-date education in science for young people planning to become elementary and high school teachers *before* they enter the classrooms where they are to work. This problem of preservice education of teachers is one which we have been concerned about for several years, for it is and has long been clear that we need to find ways of avoiding the present situation under which many of those who enter the teaching profession realize immediately after doing so that their training has been inadequate and, therefore, they have to begin at once (or should do so) to rectify a situation which should not have been allowed to develop. Again, NSF has the authority to cope with this problem: what is needed are the ideas and the funds to attack it in sensible ways. We are looking assiduously for the ideas, and hope to be able to present them (when they have been refined) in an early budget request so that we can get on with the important job of making sure that the young people who enter teaching careers are as well trained as possible when they begin to teach.

Another area is that of encouraging research in problems of current social and economic importance. Given such pressing problems as urbanization and population growth, it is possible, and well within the Foundation's authority, to support more basic research projects directly related to them. Because of the complexity of many of these problems this will, I am sure, require more concerted planning and aggressive leadership than most of our programs in the traditional scientific disciplines. Hence, one of the more effective ways that NSF might contribute to the Federal approach to such broad problems is by supporting studies on the nature of these problems and the types of research activities which can best lead toward their solution.

A-9. Why did the National Science Board recommend that NSF's original coordinating and evaluation functions go to a new group, the Office of Science and Technology?

The National Science Foundation Act of 1950 authorized the Foundation to evaluate scientific research programs undertaken by agencies of the Federal Government, and to correlate the Foundation's scien-

tific research programs with those undertaken by individuals and by public and private research groups; but did not specifically authorize or direct the Foundation to coordinate the programs of other Federal agencies. Thus, while the Foundation clearly had the authority to evaluate the programs of other agencies, it could only have assisted in securing coordination of the programs of other Federal agencies by making recommendations to the President. As the Foundation managed programs of its own, the Board and the Director did not believe that it would be feasible for the Foundation to evaluate or to endeavor to coordinate the work of other agencies while engaging in comparable operations not subject to the evaluation of another body. The Foundation, therefore, at no time attempted to exercise its evaluation function; as noted, it never had any statutory authority to itself coordinate the research activities of other agencies. Accordingly, when the establishment of an Office of Science and Technology was being considered, the National Science Board gave general endorsement to the report of a special Board committee which recommended that a continuing competence be established at a high level, such as in the Executive Office of the President, to coordinate, assess, and evaluate the state and conduct of Federal science and technology.

(See also A–10.)

A–10. How can the NSF assume a more active role in the support of science in view of Reorganization Plan No. 2 which transferred its broad policy functions elsewhere? Does the present law permit such latitude? If so, cite the part of the law which is pertinent.

Reorganization Plan No. 2 of 1962 transferred from the Foundation to the Director of the Office of Science and Technology so much of the policy functions of the Foundation authorized in section 3(a)(1) of the act as would enable him to assist the President in achieving coordinated Federal polices for the promotion of basic research and education in the sciences. In addition, the reorganization plan transferred to the Director of the Office of Science and Technology the function of evaluating scientific research programs undertaken by agencies of the Federal Government as authorized by section 3(a)(6) of the act. As the President made clear at the time, the Foundation is still expected to originate, for the consideration of the President, policy proposals and recommendations concerning the support of basic research and education in the sciences. The Foundation had never been authorized to require other Federal agencies to alter their support of science activities. The transfer of the above responsibilities made no change in the Foundation's authority to itself support scientific activities or in its obligation to strengthen basic research and education in the sciences (sec. 3(b)).

With additional funds, the Foundation could expand its activities in support of basic scientific research and programs to strengthen scientific research potential. Through the authority which it retains to initiate and support programs in the support of basic science (sec. 3(a)(3) of the National Science Foundation Act of 1950) there is ample statutory authority to assume a more active role in the support of science.

(See also A–9.)

A-11. Could copies be made available to the committee of science policy studies conducted by the Foundation in the last few years? What is the current schedule for the completion of such NSF studies now in progress?

The answer to this question is, of course, that all science policy studies conducted by the Foundation can be (and for some time past have been) made available to the committee when published. So can these for which NSF provides support, as in the case of the studies of scientific fields under the auspices of the National Academy of Sciences Committee on Science and Public Policy, when they appear. The Foundation would be happy to forward to the committee any such reports which are not now in its possession.[1]

The Foundation now has underway a series of studies which focus directly upon theoretical and empirical aspects of science policy problems. These are being conducted by members of NSF staff, consultants, and through grants to university research units. They deal with the allocation of Federal support for scientific research, case studies of allocation decisions, the question of priorities for science, the underlying assumptions in science policy planning, and related subjects. It is our hope and expectation that all or most of these studies will lead to findings or analyses that will be of interest to this committee.

Interpreting the term "science policy studies" broadly, I can list the following studies now being conducted by the Foundation, together with the current schedule for the publication of preliminary and final reports:

Title	Estimated date of publication	
	Preliminary report	Final report
Scientists and Engineers in Colleges and Universities, 1961	Issued	August 1965.
High School Backgrounds of Doctorates, 1959-62	None	Do.
Scientist and Engineer Immigration, 1962-63	do	September 1965.
Federal Funds for Research, Development, and Other Scientific Activities, Fiscal Years 1964, 1965, and 1966, vol. XIV.	do	October 1965.
Study of 1964 Graduating Classes	do	Do.
College and University Policies Governing Consulting Activities of Faculty.	do	Do.
Geographic Distribution of Industrial R. & D. Performance Funds, 1962-63.	do	Do.
Education and Training of America's 1960 Scientists and Engineers.	do	Do.
Basic Research, Applied Research, and Development in Industry, 1962.	Issued	November 1965.
America's 1960 Scientists and Engineers: Employment and Other Characteristics, 1960 and 1962.	None	Do.
Graduate Study Patterns of College Graduates	do	Do.
Current and Future Supply of Technicians	do	Do.
The College-Degree Population, 1960	do	Do.
Trends in Immigration of Scientists and Engineers, 1950-64	do	December 1965.
American Science Manpower, 1964	Issued	Do.
American Engineering Manpower, 1964	None	Do.
Employment Patterns of College Graduates	do	January 1966.
Basic Research, Applied Research, and Development in Industry, 1963.	Issued	Do.
Research and Development in Smaller Manufacturing Firms	None	February 1966.
The Recruitment of Academic Scientists	do	March 1966.
Geographic Distribution of Industrial R. & D. Performance Funds, 1964.	do	Do.

[1] We have just reissued a brochure entitled "Publications of the National Science Foundation" which lists all such studies; copies of this brochure have recently been supplied to the committee.

Title	Estimated date of publication	
	Preliminary report	Final report
Followup Study of 1961 Freshmen Classes	None	April 1966.
College and University Policies Governing Support of Graduate Students.	do	Do.
College and University Policies Concerning Nonfaculty Professional Staff.	do	June 1966.
State Government Expenditures for R. & D. Performance, 1964 and 1965.	do	Do.
Scientific Activities of Institutions of Higher Education, 1963–64	December 1965	July 1966.
Basic Research, Applied Research, and Development in Industry, 1964.	October 1965	Do.
Research and Development of Nonprofit Organizations—Expenditures and Manpower, 1964.	March 1966	November 1966.
Characteristics of the Engineering Profession	None	December 1966.
Analysis of Classification of Scientists and Engineers	do	Do.
Characteristics of Science Information Personnel	do	Do.
Estimating Engineering Manpower Needs	do	Do.
Academic and Financial Status of Graduate Students	do	January 1967.

NOTE.—See also A-13, A-14.

A-12. As a former member of the Atomic Energy Commission, whose funds must be authorized annually, do you see any advantage or penalties to this procedure as compared to the continuing authorization now available to the Foundation?

There are many significant differences between the purposes and objectives of the Atomic Energy Commission and those of the National Science Foundation. The act establishing the Atomic Energy Commission predates by only a few years the act establishing the National Science Foundation. In establishing the Atomic Energy Commission, the Congress very wisely perceived the need for specific legislation relating to the development, use, and control of atomic energy. Science had produced a new and awesome energy source which required Government regulation at the highest level.

During the period when I was one of the members of AEC, only the component of the Commission's budget related to major new facilities construction was subject to annual authorization action. In those days, therefore, authorization hearings before the Joint Atomic Energy Committee were not completely parallel to the current situation under which all Commission appropriations are subject to annual authorization. Even so, they did provide important opportunities to exchange information and views with the Congress, particularly in view of the fact that the Commission's involvement with large facilities was then (as it is still) a very significant facet of its entire operation. These appearances to review plans for major facilities usually permitted the members of the committee to explore some problems in reasonable detail. But of at least equal value, in my view, were the numerous special hearings on substantive issues—hearings which explored technical and administratively difficult matters in great depth and with a spirit of genuine mutual interest. During these interchanges, the Commission was able to share ideas with and to learn from the Congress; and, in turn, the Congress was able to develop a fuller appreciation of the agency's programs and problems.

The Congress, in enacting the National Science Foundation Act, recognized the principle that basic science progresses best in an at-

mosphere of free intellectual inquiry. This broad legislation has enabled the Foundation to develop a highly productive relationship with working scientists and academic institutions. Many fine programs have evolved from this cooperation and some of these programs influenced recent Federal aid to education legislation.

Both as a scientist and as a public official concerned with the administration of scientific programs, I naturally would prefer to retain the broad continuing authorities contained in the National Science Foundation Act. Generally, I do not believe that authorizing legislation would materially affect the management of appropriated resources. This committee, like the Joint Committee on Atomic Energy, would, I am sure, give careful consideration to scientific judgments in connection with its consideration of authorizing legislation. The key point in answering your question depends, to a large extent, on the manner in which the Congress would implement such legislation. One of the strong points of the present legislation is the flexibility which is afforded the Foundation in working out the most effective programs with academic institutions and scientists. Annual authorizing legislation in addition to appropriation legislation, potentially at least, has the prospect of curtailing this flexibility—thus leading inevitably to some additional administrative rigidity. The extent of this rigidity is dependent in part upon the nature of the provisions of authorizing legislation. An offsetting factor on the plus side of the question is the fact that hearings on annual authorization legislation would offer an opportunity to discuss Foundation goals and related programs in a broader context than is possible during an appropriation hearing. This would provide a decided benefit by promoting a wider knowledge and improved understanding of the Foundation's programs on the part of a greater number of members of the Congress. I would like to point out here, however, that my experience during the period I served on the Atomic Energy Commission clearly demonstrated that substantive hearings in depth, not directly coupled to the appropriations process, can provide the opportunity for valuable exchange of information and views.

Whatever course of action is adopted by the Congress, I sincerely hope we may have the opportunity of presenting our programs to you in substantive detail and with somewhat greater frequency than heretofore.

A-13. Can you give examples, both before and after the establishment of OST, of the formulation by NSF of science policy guidelines that have been applied across the Government?

A-14. Is there any system, formal or otherwise, of check or follow-through on NFS's reports and recommendations to OST for example, or to other agencies? How are the Foundation's findings generally implemented?

There have been a number of instances in which policies for science, formulated and recommended by the Foundation, have been adopted as Government-wide policy. In addition, of course, there have been many instances in which the Foundation collaborated with other agencies of the Government, including the Bureau of the Budget, OST, the Federal Council for Science and Technology, and agencies which support scientific research, in the development of policy. Among the latter

may be cited, for example, policies pertaining to reimbursement of indirect costs, establishment of fellowship stipends, cost-of-education allowances, etc.

The following are examples of the first type, that of direct policy formulation and recommendation by the Foundation followed by adoption for Government-wide use.

Federal support of "nonsensitive" research.—Early in its operations, the Foundation established its policy relating to support of nonsensitive (unclassified) research not involving considerations of security. Briefly stated, the policy developed was that, in appraising proposals submitted by or on behalf of scientists for support of unclassified research not involving considerations of security, the Foundation would be guided by the judgment of scientists having a working knowledge of the individual's qualifications as to experience, competence, and integrity. However, the Foundation would not knowingly support the work of an avowed Communist or anyone established as being a Communist by judicial proceedings nor that of an individual convicted of sabotage, espionage, sedition, subversive activity under the Smith Act, or a similar crime involving the Nation's security.

This policy was endorsed by the American Association for the Advancement of Science in December 1954. Later, the White House requested the National Academy of Sciences to appoint a special committee to study the problem. In its report to Sherman Adams, assistant to the President, that committee essentially endorsed the Foundation's policy. The assistant to the President responded by indicating that the policy appeared satisfactory to all concerned and stated, in part, "It is noted that these principles are essentially those which support the policy of the National Science Foundation. The departments and agencies will, therefore, follow practices consistent with the recommendations contained in the report of the Academy's Committee." This national policy has remained in force since that time.

East-West exchanges of scientific information.—A Foundation report in 1955 "Preliminary Report on Role of the Federal Government in International Science," National Science Foundation, December 1955) recommended the necessity "to increase the flow of scientific and technical information received from Russia on an exchange basis." As is well known, this concept later became national policy which was formalized in the U.S.A.-U.S.S.R. agreement (the so-called Bronk-Nesmeyanov agreement) of July 9, 1959, for exchange of scientists between the United States and Russia. This agreement has been renewed several times and continues to date.

Government role in research on synthetic rubber.—In December 1955 the Foundation made a series of recommendations ("Recommended Future Role of the Federal Government With Respect to Synthetic Rubber," Report of Special Commission for Rubber Research, National Science Foundation, December 1955) with regard to the Government-sponsored rubber research program which had originally been started as a World War II effort. These recommendations included (*a*) termination of the program, (*b*) substitution of a new program of basic research in related areas, and (*c*) sale of the Government laboratories which were then being used for the synthetic rubber research program.

The Foundation's recommendations were accepted and were fully implemented during calendar year 1956 by administrative and legislative action.

Extension of grant authority to other agencies supporting university research.—On a number of occasions the Foundation recommended that all Federal agencies which support research at institutions of higher education should be authorized to use the grant mechanism, as well as contracts, for support of such research. This recommendation was formally stated in April 1958 ("Government-University Relationships in Federally Sponsored Scientific Research and Development," National Science Foundation, Apr. 1, 1958) as follows:

> It is recommended that, where such authority does not now exist, legislation be sought to authorize Federal agencies, where appropriate, to support scientific research, including facilities and equipment, by means of grants as well as contracts.

This recommendation was enacted into law by the 85th Congress, 2d session, in the form of Public Law 85-934 and was signed by the President on September 6, 1958.

Criteria for support of scientific publications.—A set of criteria for support of scientific publications, journals, monographs, etc., was developed by the Foundation for use in its own programs. These criteria were presented to other Federal agencies and the Federal Council for Science and Technology. They were adopted by the Federal Council on August 1, 1963, and were then disseminated by the Office on Science and Technology as a Federal policy on Federal support of nongovernmental scientific and technical publications.

Strengthening academic capabilities for science throughout the United States.—In a statement presented to the Federal Council's Long Range Planning Committee on May 28, 1964, I reiterated a comment (which I first made to this subcommittee 3 weeks before) concerning the desirability of all agencies of Government seeking out "pockets of strength" wherever they may be located in universities throughout the country and providing support to help develop further the scientific capabilities in such institutions.

I noted that (*a*) helping to develop research potential throughout the Nation is a prime responsibility of the National Science Foundation, but that other agencies must play their part; (*b*) NSF is convinced that additional steps can be taken to assure a wider distribution of research support in academic institutions throughout the country; (*c*) the Foundation, therefore, plans to seek support for a new program designed to attack this matter directly, but it also is determined to reexamine its present evaluation procedures to make sure that they do not have built into them any elements which discriminate against developing institutions. I concluded by saying, "We believe that other agencies might profitably engage in a similar exercise."

Later, I reformulated and particularized these ideas, and submitted them to the Federal Council itself for consideration; these were the ideas embodied in the "four courses of action which should be followed in the effort to optimize academic science and science education throughout the country" to which I referred in my testimony before this body on June 25, 1965.[1] As I mentioned at that time, these sug-

[1] This appeared on pp. 151-154 of the transcript of the hearings.

gestions, modified as a result of FCST discussion, have been adopted in principle by the Federal Council, and plans are going forward to have them enunciated in an appropriate fashion as guidelines for all science-supporting agencies.

The most readily available channel for consideration of NSF recommendations are the committees and panels of the Federal Council for Science and Technology. This mechanism provides a formal means for consideration leading to action on the part of Federal agencies. Although there is no formal system for "checking" on the use made of reports which the Foundation provides to OST or any of the Federal agencies, this does not mean that the Foundation is deprived of knowledge on this score. Such knowledge is obtained in three ways: Through an informal system of continuing communication maintained by staff members of the Foundation with those of other agencies, through the work of interagency committees, and through references made to NSF reports in published and unpublished documents of other agencies which are made available to the Foundation. There are presently no compelling reasons for believing that the cost of creating other procedures and mechanisms for checking on the use made of Foundation reports would be justified.

Findings of the Foundation's varied studies are taken into account in a variety of ways. For example, the work of the President's Science Advisory Committee which led to the recommendations embodied in "Meeting Manpower Needs in Science and Technology" was based in large measure on a number of studies carried out by the Foundation. Special studies and analyses of the manpower situation in the field of oceanography have led to detailed consideration by the Interagency Committee on Oceanography of mechanisms for motivating more students toward training in oceanography and closely related fields.

On a somewhat different plane, Foundation studies of the investment in research and development serve as a widely used body of reference material for all those concerned with making decisions on the future of the scientific enterprise in the United States.

Special staff studies and recommendations for action—on the part of the Foundation itself or other agencies—are prepared from time to time, and the ways in which these documents are dealt with are specific to the nature of the case.

A–15. The point was brought out during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency "x," agency "y," or both. What guidelines or criteria has NSF established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the agency's jurisdiction and, therefore, should, or should not, be supported by the agency? If written criteria have been established, please submit a copy thereof to the committee.

It would not be inappropriate for us to reply to this question in full by saying:

> The NSF Act of 1950 "directs and authorizes" the Foundation to initiate and support basic scientific research * * * in the mathematical, physical, medical, biological, engineering, and other sciences * * *" in a wide variety of ways. Thus,

Congress, in our basic law, established for us the criteria under which we must and do operate in determining whether a project is or is not "within the purview or scope" of our jurisdiction.

Although this is an accurate and (in a sense) complete response, I feel that it would be useful to analyze the implications of this question in some detail.

From a consideration of our statutory authority, it is clear that NSF can support (with a few special exceptions) only *basic* research projects. In our discussion below, therefore, we will be focusing on this area; in effect, this means that we have assumed the word "basic" precedes "research" at each point where the latter is used in question A-15.

The principal guideline that has been established to provide a somewhat more specific delineation of jurisdiction in supporting basic research projects is Executive Order 10521, section 4, which states:

As now or hereafter authorized or permitted by law, the Foundation shall be increasingly responsible for providing support by the Federal Government for general purpose basic research through contracts and grants. The conduct and support by other Federal agencies of basic research in areas which are closely related to their missions is recognized as important and desirable, especially in response to current national needs, and shall continue.[1]

Furthermore, one of the functions of the Federal Council for Science and Technology, which was established by Executive Order 10807, is to—

* * * consider problems and developments in the fields of science and technology and related activities affecting more than one Federal agency or concerning the overall advancement of the Nation's science and technology, and shall recommend policies and other measures (1) to provide more effective planning and administration of Federal scientific and technological programs, (2) to identify research needs including areas of research requiring additional emphasis, (3) to achieve more effective utilization of the scientific and technological resources and facilities of Federal agencies, including the elimination of unnecessary duplication * * *.[2]

These criteria and mechanisms assist in defining, in general terms, the role that each Federal agency will take with regard to scientific research—particularly basic research. However, in considering the day-to-day determinations that must be made in the administration of research programs, it is important to bear in mind that each proposal is an individual case and each has its own special characteristics and dimensions which may or may not be appropriate to the emphases and goals of a particular agency. These considerations continually guide agency administrators in assessing how or where a particular project might best be reviewed and (possibly) funded.

When the Foundation receives a proposal that might be of greater interest or be more appropriate to another agency, such as the Office of Naval Research or the Atomic Energy Commission, the Foundation staff normally checks to see whether the proposal has been submitted to that agency. Conversely, the program officers of mission-oriented agencies frequently suggest that basic research proposals submitted to them be sent also (or instead) to NSF. Section 4 of Executive Order 10521 (quoted above) is obviously an important guid-

[1] Mar. 17, 1954.
[2] Mar. 13, 1959. This Executive Order 10807 amended Executive Order 10521 in part, but did not change sec. 4 (quoted above).

ing statement in such cases. When a proposal is submitted both to NSF and to another possible sponsor, the coordinating mechanisms dealt with in our response to question B–14 are of major importance in the further handling of the matter. Jurisdictional disputes are very rare since there are more meritorious projects to be supported than the combined funds of all the agencies can take care of.

The above discussion deals with general unsolicited proposals for basic research. A notable exception is the case of proposed Antarctic research projects, where the determination of agency responsibility has been made clear through Bureau of the Budget Circular A–51, dated August 3, 1960. Section 4.b. of this circular states:

> Federal agencies interested in scientific activities for Antarctica, either to be conducted by their own staffs or by other agencies and personnel, should inform the National Science Foundation of their interest and of the content of proposed scientific activities that might be included in the U.S. scientific program to be developed and funded by the Foundation. (See also the response to question F–8.)

All proposals regarding Antarctic research received by other agencies are, therefore, immediately referred to the National Science Foundation.

As noted at the beginning of this response, within the National Science Foundation the basic guideline used by all personnel to determine whether a proposal falls within the Foundation's purview is our basic act, Public Law 507, 81st Congress, as amended. This act constitutes the fundamental body of policy which guides all actions. Various subsidiary "interpretative" actions are of course necessary. (See A–19 for an example.)

For practical purposes, guidelines for basic research support are summarized in the booklet "Grants for Scientific Research," which is issued both to guide scientists who are interested in submitting proposals to the Foundation and to provide a "frame of reference" for our own staff. This booklet can be viewed as a summary in operationally useful language of many policy decisions, since it defines the areas supported and discusses ground rules for different classes of applicants; the following relevant excerpts from it may be useful:

TYPES OF BASIC RESEARCH SUPPORTED

> The National Science Foundation will entertain proposals for support of basic research in science. The fields of science supported include but are not limited to: astronomy; atmospheric sciences, including weather modification; biological and medical sciences, including developmental, environmental, genetic, metabolic, molecular, regulatory, and systematic biology, also psychobiology and biological oceanography; chemistry; earth sciences, including physical oceanography; engineering sciences, including chemical, civil, electrical, and mechanical engineering, metallurgy, engineering mechanics, and associated interdisciplinary activities; mathematical sciences; physics; and social sciences, including anthropology, archeology, social psychology, sociology, economics, demography, linguistics, economic and social geography, and the history and philosophy of science.[1]
>
> Foundation support of basic research is given not only to specific projects, but also to programs covering a coherent area of science. Support for graduate thesis research may be included in proposals of either type * * *.

[1] Since the latest version of the booklet was printed, we have announced that political science is now explicitly included also.

WHO MAY SUBMIT

The Foundation considers all requests for support of basic research, regardless of source. Normally, proposals are initiated by the scientist interested in doing the work, and in most instances a formal proposal is submitted on his behalf by his organization. The proposal may, prior to formal submission, be the subject of informal discussions between the scientist and the Foundation staff, either by letter or in person, but this is not required. Graduate students are not encouraged to submit proposals for support of research; instead, they should normally apply either for fellowship support or arrange to serve as research assistants to faculty members holding grants.

Proposals are submitted by five different categories of applicants.

(1) Colleges and universities: The great majority of proposals received by the Foundation are submitted by U.S. universities and colleges on behalf of their staff members * * *.

(2) Nonprofit research institutions: The Foundation's present policy is to emphasize support of research which also contributes to graduate and postdoctoral education in the sciences. Hence, grants will normally be made to nonprofit institutions only when they can demonstrate a close relationship to such education. However, special consideration will be given when the proposed research is judged to be of exceptional significance or where the institution has unique capabilities * * *.

(3) Private profit organizations: The Foundation does not normally give support to basic research performed in private profit organizations. However, under exceptional circumstances support may be considered if one or more of the following criteria are met: (*a*) The research is of special concern from a national point of view and shows unique promise of solving an outstanding scientific problem; (*b*) unique resources are available for the work; or (*c*) the research is of outstanding excellence and will make significant contributions to the training of scientists. Such support is accomplished through the execution of an appropriate form of nonprofit contract rather than by grant.

(4) Foreign institutions: The Foundation provides a limited amount of support to foreign institutions for the conduct of basic research when such action is consistent with the Foundation's responsibilities and objectives * * *.

(5) Individual scientists in the United States: Under special circumstances grants may be made to individual scientists. Before a formal proposal is submitted it is suggested that preliminary inquiry be made to the Foundation.

(See also B-14-E-8; C-4; F-8.)

A-16. We are learning by experience and technical study that land drainage is in truth a science, involving much more than hydrology and soil mechanics—such as, for example, in agricultural areas the chemistry of soils under the influence of fertilizers and pesticides, and the complex reactions which rainfall or irrigation runoff from the land produce in our rivers and bays; and, of course, in urban areas the resulting problems of water pollution by detergents, sewage, and industrial waste. The question is, Do you consider such research within the purview of the National Science Foundation? If so, will you venture into this field at all?

Any proposal for the support of basic research can be submitted for consideration by the Foundation. Therefore, we have supported projects that relate to hydrology, soil mechanics, stream erosion, chemistry of natural waters, biological problems associated with land drainage, etc. Because water resources and land drainage are interdisciplinary in character these proposal are handled in a number of our program offices, e.g., chemistry, engineering, earth sciences, environmental biology, etc.

Many of the types of problems listed in the question fall within the purview of the Public Health Service or the Agricultural Research Service. In addition the recently established Office of Water Resources Research in the Department of Interior also sponsors research in water

resources. All of these agencies are represented on the Committee on Water Resources Research, FCST, and the development of the national program and coordination to avoid duplication is accomplished through the Committee. The Committee is acutely aware of the need for a broader and more cohesive approach to the planning and management of water resources. Indeed, the Committee is currently drafting a recommended long-range program in this field. It seems wise to await the recommended long-range plan before deciding what further step should be taken in the field of water resources. For the present the Foundation plans to continue supporting good proposals in this field, but has no plans to set up a special office dealing with this subject.

A–17. How does the Foundation encourage the acceleration of those areas of science for which it believes growth is needed in the national interest?

When an area of science has been identified by the Foundation as being in need of accelerated growth, the Foundation first attempts to ascertain the nature and extent of the need. This assessment may be done through our own efforts, through consultations with the appropriate advisory committees of the Foundation, or through advisory groups which may be convened by the National Academy of Sciences or other qualified scientific organizations. When the extent of the need has been established, a determination is made as to whether the expanded effort can be accomplished through increased support of scientists already trained in the research area in question and at the institutions where they are located at the time. If this is not the case, it may be decided that scientists from related areas of research should be encouraged to turn their attention to one that needs encouragement, and new organizations created for the purpose of managing the research. The attached memorandum to the Foundation staff provides details on these procedures.

The area of systematic biology provides an excellent example of Foundation encouragement of neglected science areas. When, early in its existence, the Foundation examined the areas of biology which needed special assistance, it determined to establish a systematic biology program as means of providing special support. More recently it became apparent that rising costs and space shortages had caused many universities to donate their systematic research collections to museums. Furthermore, major natural history museums, all nonacademic, were beginning to bear a heavy burden in supporting these collections, and graduate students, for lack of support, were inhibited from using them. The Foundation therefore started to foster cooperative arrangements between these nonacademic museums and nearby universities such that interested students could pursue their academic research work at, and gain support through, the museums—while still retaining traditional ties and curricular control through their universities.

Some 7 or 8 years ago it was determined that university research in inorganic chemistry was lagging in this country. On the recommendation of the Foundation's Advisory Panel for Chemistry, a separate program was established with responsibility for inorganic and analytical chemistry. In this case, enough trained manpower

51–204—65—vol. II——7

was available at universities so that the desired acceleration of effort could be obtained by providing more support through research grants to these people.

At about the same time, it was decided that the national interest required a marked increase in the basic research effort in the atmospheric sciences. To meet the need, a program for atmospheric sciences was established in the same manner, but it was felt that because of the importance and complexity of this type of research, more people having a broad spectrum of abilities in physics, chemistry, and astronomy should be brought into the effort and that special facilities and laboratories should be provided for their use. In order to accomplish this, the National Center for Atmospheric Research was established at Boulder, Colo.

A fourth example relates to the Gilliland committee report on the needs for engineering manpower. The NSF traineeship program established in fiscal year 1964 for engineers and subsequently expanded to the other sciences, is a direct outgrowth of the deliberations of a panel established to define a national problem.

(See also C-4.)

A-18. Does NSF now assert a higher degree of control of its grants than it did in earlier years? Do grants tend to shorter duration? If so, why?

Through the years the Foundation has taken specific steps to bring about a more systematic control of the fiscal and managerial—as contrasted with the scientific—aspects of its grants. In the early years of the research grants programs only grants that were for unusually large amounts or for unusually complex projects were accompanied by budgets specifying the amounts intended for various cost categories. As appropriations and programs grew larger, the early guidelines which had been promulgated primarily for basic research, but which were also frequently used for science education proposals, were supplemented by more specific suggestions which experience had shown to be desirable in evaluating proposals. This became more important during the period fiscal year 1958 to fiscal year 1960 as the Foundation's appropriations increased and the variety of program activities was expanded. In 1958 certain of the larger science education programs began utilizing budget forms to facilitate administrative review of proposals.

In addition to these suggestions regarding the development of proposals, the Foundation systematically prepared guidelines for the administration of specific aspects of projects by grantees, particularly in science education. These evolved from meetings of university representatives, science education project directors and Foundation program administrators. One of the earliest meetings of this nature was held in 1955. From this early start has grown a series of published guides for project directors which cover all major aspects of the financial and administrative "understandings" that relate to NSF grants in the area of science education, and the fellowship and traineeship programs.

As early as fiscal year 1957, letters notifying institutions of the award of grants in certain Foundation programs were routinely accompanied by a detailed budget specifying the grant amounts intended

for various cost categories, such as salaries, equipment, supplies, stipends, travel, and the like. Early in 1963 a decision was made to include such specific budgetary information with all Foundation grant notifications. In fiscal year 1966 a study will be initiated to attempt to determine whether or not our present practices introduce too great a rigidity, especially in research grants.

The Foundation has found it particularly essential to adopt systematic administrative controls with respect to its grants for the construction of facilities. It is now the practice to review final working drawings to determine specifically what is to be constructed with Foundation support. Where two or more Federal agencies join in the support of a new facility, it is now incumbent upon the institution to delineate those components of the facility which are to be supported by each. The Foundation established an architectural unit in fiscal year 1964 to serve both the institutions and the Foundation in these matters.

Because of limitations on the availability of funds, grant durations for support of some basic research areas, notably in the mathematical and physical sciences, have declined during the last 4 years from an average of more than 2 years to less than 1¾ years. During this period, the funds available in the Foundation for the support of research remained nearly constant, while the number of investigators (particularly young ones) meriting support continued to increase. At the same time the cost of research per investigator also increased. In order to provide support for additional investigators during this period, some funds which would ordinarily have been used to provide longer grant durations were used instead for support of new investigators. Nearly all projects for education in the sciences have been funded for only 1 year at a time, and therefore the average duration of this type of grant has not significantly changed. This decline in the average duration of grants is inconsistent with the longer-range nature of basic research activities, and increased the administrative costs involved in reviews and renewal of support for activities which would normally be funded over longer periods. The Foundation is seriously concerned about this and is seeking means to reverse the trend. We are currently developing plans for instituting a type of "continuing grant" which, by means of a letter of intent will assure continued support (for periods up to 5 years) for outstanding basic research investigations with a minimum of administrative review. By means of such "continuing grants"—typically involving an initial award for 2 years, followed by annual extensions—leading scientists would be given commitments by NSF of longer-term support for their studies (provided that funds are available), even though funds would rarely be committed for more than 2 years at any one time.

A-19. How can you support basic research in engineering? Doesn't the term "engineering" by definition run counter to basic research? What is NSF's policy in this regard?

Under section 3(a) (2) of Public Law 507, 81st Congress, the Foundation is authorized and directed—

> To initiate and support basic scientific research and programs to strengthen scientific research potential in the mathematical, physical, medical, biological, engineering, and other sciences, by making contracts or other arrangements (including grants, loans, and other forms of assistance) to support such scien-

tific activities and to appraise the impact of research upon industrial development and upon the general welfare; * * *

Thus, support of the "engineering sciences" is specifically authorized by statute. The accepted engineering sciences include, for example, mechanics of fluids and solids, thermodynamics, transfer processes, electrical theory, and the nature and properties of materials. (More lengthy definitions can be found, for example, in the Journal of Engineering Education, vol. 45, No. 1, pp. 37–91.)

In order to clarify still further the Foundation's operating definition of basic research in engineering, the National Science Board on May 15, 1962, adopted the following resolution:

***Resolved,* That the National Science Board considers that intellectual pursuits at educational institutions intended to advance significantly the basic engineering capabilities of the country are eligible for support by the National Science Foundation as basic research in the engineering services. Such work must be of a true scientific nature and not routine engineering practice, and must meet the usual NSF standards of originality and excellence.**

This definition includes types of research and engineering such as:

(*a*) The development of principles and techniques in a systems engineering design;

(*b*) The development of principles and a philosophy for creative engineering;

(*c*) Interdisciplinary research related to such matters as biomedical engineering, transportation, urban planning, fire prevention, etc.;

(*d*) The principles of generation and control of energy systems and information systems;

(*e*) Analysis and synthesis of processes and systems which contribute to mastery of the environment.

As always, the merit and importance of the proposed research continue to be essential factors for favorable action.

A–20. Are there fields of basic engineering in which the Foundation might play a much larger role than in the past? Can you envision NSF research grants to study such problems as the functioning of columns, rotating machinery, and energy transmission by fluids? How about long-distance energy transmission by extra high voltage electric powerlines? Would the Foundation support technoeconomic research of the national problem of intermodal transportation?

There are areas of basic engineering for which grant support could be increased, within the quality criteria now employed. Grants to study such problems as the functioning of columns and energy transmission by fluids have been made. The following examples are listed from grants made in fiscal years 1963 and 1964:

I. Functioning of columns

1. "Stability of Compression Members," Nicolaas Willems, University of Kansas, GP–3064.

2. "Dynamic Stability of Beam Columns With a Fixed Distance Between Supports," Nicholas F. Morris, New York University, GP–2245.

3. "Stability of Columns and Plates Subject to Time Dependent Loads," Ross M. Evan-Iwanowski, Syracuse University, GP–840.
4. "Experimental Postbuckling of Elastic Plates," C. H. Chang, University of Alabama, GP–551.
5. "Stress Distribution in Prestressed Members," Joseph H. Moore, Clemson University, GP–347.

II. Energy transmission by fluids

1. "Heat Transfer to Non-Newtonian Fluids," B. Goodwin, Northwestern University, GP–3007.
2. "Thermal Conductivities of Fluids," R. Graff, New York City College, GP–3129.
3. "Magneto-Fluid Dynamics," H. Ahlstrom, University of Washington, GP–3065.
4. "Fundamental Studies in Viscous Flow," S. Kline and W. Reynolds, Stanford University, GP–2720.
5. "Turbulent Jet Mixing Considering Effects of Initial Boundary Layer," Morris E. Childs, University of Washington, GP–2038.

The extra high voltage power transmission problem is not now the subject of a grant, but suitable proposals in this area could be considered, subject to the usual criteria for research quality. As for technoeconomic research of the national problem of intermodal transportation, NSF could support high quality university-type research on selected aspects of the transportation problem, but it obviously could not at present support a major applied or developmental effort on this subject. NSF could probably support (and indeed is currently considering the initiation of) a study designed to provide a better understanding of present (and probable future) technical and economic characteristics of national and regional transportation systems involving all modes of transport as a possible framework for applied research supported and carried out by other organizations and of basic research in universities, to be supported, in part, by the Foundation.

A–21. Would you please provide data on the geographical distribution of all the applications for support which the Foundation receives; that is, for fellowships, traineeships, research grants, and institutional grants, in each of the following categories: (1) Those requests which are found to be not qualified for support; (2) those requests which are qualified, but are not supported because of insufficient money; and (3) those requests which are qualified and supported. This information is desired in terms of numbers and dollars for the past 3 years, if possible.

The attached tables include information on the geographic distribution of grants and declinations for fiscal years 1963, 1964, and 1965. Declinations have not been allocated to categories (1) and (2) of the request since data have not been recorded in this precise form in the data processing center. Our experience indicates that only a minor percentage of the proposals we consider could be judged to be completely without merit and, therefore, would not have been eligible for some support had sufficient funds been available.

Tables are included for (*a*) fellowships; (*b*) traineeships;[1] (*c*) science education support (exclusive of fellowships);[2] and (*d*) basic research project support grants. It should be noted that the tables for the first two categories differ from the second two categories in one minor respect: for fellowships and traineeships we show awards as contrasted with all *applications;* for the science education and basic research projects grants, we show awards as contrasted with *declinations.* Institutional grants are a special case since these grants are awarded by formula to all schools that are eligible and that request the institutional base grant; thus the group of applicants is limited—and the group receiving grants is the same group, since there are no declinations. A table showing the distribution of these grants by States for fiscal years 1961–65 is included. Tables have been provided on the distribution of graduate science facilities, including construction and renovation of research and graduate level instructional laboratories. Only 10 grants have been announced in the science development program, another special purpose program for institutional support. A table showing the geographic distribution of these grants is also included. Since final decisions are still pending on most of the proposals received in this program, no analysis of declinations is currently possible.

Tables have not been provided on the geographic distribution of grants and declinations for national research programs, specialized research facilities support, national research centers, and science information services because of the specialized nature of these activities.

---

[1] Data on traineeships for fiscal year 1964 (the program's first year) and for fiscal year 1965.

[2] The data on traineeships, shown separately in (b) as indicated, are also included in the tables headed "Science Education Programs."

[1] During the 1st year of operation of the NSF graduate traineeship program (fiscal year 1964) awards were limited to the engineering fields, and only institutions awarding the Ph. D. in 1 or more engineering departments were eligible to submit proposals.

[2] No institution in State was eligible to apply (i.e., none had Ph. D. degree granting program in engineering).

A–22. In the new field of technology utilization, what is the Foundation doing to increase knowledge of this subject? What is its role in this respect, in relation to NASA, the Department of Commerce, and the Atomic Energy Commission?

The National Science Foundation has no primary assigned role in this respect in relation to other Federal agencies which may be concerned. The Foundation does participate in various information exchange programs, and tries to insure that scientific results reported by grantees will be promptly reported in the appropriate journals. In this respect the Foundation's activities in the support of scientific and technical information and in the collection of data on technology are important adjuncts. The regular collection of data on the scientific and technologic effort in industry leads to a better understanding of the patterns of technological activity. In addition, NSF's support of the National Referral Center of the Library of Congress complements the Clearinghouse for Technical Information of the Department of Commerce in providing industry with information on the sources of scientific research activities. NASA, the Atomic Energy Commission, the Department of Commerce, as well as NSF, cooperate in making these centers effective transfer agencies for technical information.

This general field is one in which I believe we should be more active.

B. NSF Organization and Budget

B-1. When the NSF was created in 1950 with a budget limited to $15 million, the National Science Board could, presumably, exercise close supervision over the workings of the Foundation. Since that time, the budget of the Foundation has increased to about $480 million and the Board has delegated much of its authority to the Director, keeping for itself the authority for major policy decisions. In effect, then, the Board serves as a sort of board of governors, and is one of the few nonregulatory agencies with this form of dual (Board and Director) authority and responsibility. The question arises: Is it in the best interest of the country and of science in general to still maintain this dual authority, or would it perhaps be better to have the Director solely responsible for the operation of the Foundation, and have the Board serve in an advisory capacity to the Director (a national science advisory board)?

First let me say that the National Science Board, from its inception, has brought a rare sense of dedication to its task. On some occasions all members have been present at its meetings—never has there failed to a be quorum. Its experience and wisdom have been vital to the evolution of wise policies and programs for the Foundation and have afforded to Government a broad view of the role and needs of science not only in the academic community, but in the country as a whole.

The Board and the Director have always worked together in close and harmonious partnership and no serious problems have arisen. However, the present statute does have certain weaknesses. The statutory distribution of responsibilities and authority between the National Science Board and the Director could make it impossible, in an extreme situation, for the Foundation to act. The Director is appointed by and is responsible to the President and must be responsive to the Congress but, in carrying out his responsibilities he is, by virtue of the present statute, subject to policy and other determinations of the Board. This arrangement, therefore, carries within itself the possibility of the Board being in disagreement with actions proposed by the Director pursuant to policies of the administration and the Director being unable to function because of the reservation to the Board of responsibility for determining policy and for approving grants and contracts.

A more immediate practical problem is that the lodging of these responsibilities in the Board raises the difficulty that the Director is frequently faced with the need for taking actions which should be taken promptly but must await the convening of the Board. Moreover, the broad responsibilities which the present statute vests in the Board places a burden on the individual members who are in intimate touch with Foundation activities only on an intermittent basis. While as a Board they are ultimately responsible, they are quite literally unable to be sure that their responsibility is adequately fulfilled in all

matters. This situation has been somewhat alleviated through the Board having transferred to the Director, pursuant to a recent amendment to the act, much of its burden of detailed decisionmaking; it could be further relieved by amending the act to permit the Board to delegate to the Director or its Executive Committee such of its policymaking functions as it deems desirable.

Within the limits of his responsibilities to the President and the Congress, it seems very unlikely to me that any Director of the National Science Foundation would ever ignore or override the views of a distinguished group appointed by the President, with the advice and consent of the Senate, and representative of scientific research and education activities throughout the country. I do not believe, therefore, that there would be any real difference in the Board's influence stemming from whether it were made advisory or whether it retained its statutory responsibilities. The importance of the Board is not that it has legal authority to make decisions but that as a truly independent body it can forcefully represent the views and needs of the scientific and educational communities. Its independence might even be enhanced if changed to an advisory body since there would then be no constraint on its openly questioning governmental policy with which it did not agree.

B-2. Since the Foundation's budget increased almost $100 million between fiscal years 1963 and 1965 why have both the total and scientific professional personnel remained at or below the fiscal year 1963 levels?

The Foundation's employment level need not rise in direct proportion to increases in appropriations. As the agency matures, NSF has been taking advantage of the increased experience of its staff and of the improvement and standardization of procedures.

In line with this philosophy, a review of position management practices was conducted in 1963 by the Office of the Director which resulted in the adoption of new controls and the issuance of guidelines concerning personnel and position management. The assignment by the Office of the Director of specific employment ceilings for each major subdivision based on a detailed analysis of individual programs is cited. Formerly, only dollar limitations were imposed on the operating offices. Another factor which contributed to the maintenance of a stable employment ceiling was the emphasis given to reviewing the balance of workload among the offices and divisions. These continuing management reviews have led, in some cases, to reductions in staff in several offices which offset increases elsewhere. In addition, the use of consultants serving on an intermittent basis, has contributed to the stability in the employment of full-time employees. The number of consultants has increased in the period 1963-65 from 483 to 587. If the expert services of these highly qualified individuals were not available to the extent they are, the number of full-time employees would have to be increased considerably.

It may also be noted that while the total scientific and professional employment at grade GS-11 and up has remained constant, the quality of this group has been steadily upgraded. From July 1, 1963, to June 31, 1965, the number of scientific and professional employees at grades GS-15 and above has increased by 31. During this period the establishment of the Mohole project office and the Office of Program De-

velopment and Analysis, and the reorganization of the education area into three separate divisions all entailed increases in high-grade scientific and professional positions. It should be emphasized that this augmentation was the result of a deliberate policy designed to strengthen the management and control of our research and education programs, while enhancing our capability for more effective planning.

B-3. How has the Foundation determined the proportion of its budget to be devoted to statistics-gathering and analysis and why has this not grown in proportion to the NSF budget and to the Federal-wide research and development budgets? For example, why has the Foundation allocated more funds for research concerned with science information systems than for analysis and planning of national resources for science and technology?

As is the case with reference to any particular Foundation activity, budget estimates are based upon a number of considerations such as the program's history, the current priority of the function, the estimated cost of any planned expansion or change in the activity, etc. Budget allocations for the Foundation's statistics-gathering and analysis have grown over the past 5 years from a level of $1.6 million in fiscal year 1963 to a level of $2.3 million in fiscal year 1966. The NSF budget over this same period has evolved from approximately $322.5 million in fiscal year 1963 to $480 million in fiscal year 1966. The figures for the total Federal R. & D. obligation for these years are $13.7 billion and $16 billion plus, respectively.

While the rate of growth in allocation of funds for statistics-gathering and analysis is proportional to the growth in NSF's overall budget and greater than that in total Federal R. & D. funds over the same period, the relationship should not be conceived as a rational one. There is, in fact, no obvious reason why there should be any direct relationships between the growth rates.

The advent of new program functions (the science development program, for example) during any period can result in a sharp increment in the Foundation's total budget without having any effect on statistics-gathering and analysis operations. Conversely, one can imagine circumstances where program budgets would remain constant while statistics-gathering operations might be sharply increased.

A large portion of statistics gathering that is required for policy studies is done through Government agency channels, utilizing staff that are on the payrolls of the various agencies. In the case of studies that are done under grants or contracts, these in large measure cover expenses for personal services and are not easily compared in cost to "research concerned with science information systems." In the case of the latter, such research frequently involves the utilization of computer time and the experimental use of various computer systems. If, as in the case with research on the proposed national chemical information system, the problem involves the development of computer systems for handling information, the work is extremely costly.

The importance of statistics gathering and analysis has been recognized in the Foundation in the sense of increasing the number of staff and the level of staff devoted to this function. Likewise, funds allocated for science information functions have been increasing and will increase even further if a major effort regarding "national systems" is launched by the Foundation. However, as has been indicated above,

a comparison between these two portions of the Foundation budget is not a very relevant one.

(See also G-5.)

B-4. Referring again to the charts you introduced at the hearings, please furnish a more detailed explanation of "Executive branch science coordination" (chart No. 3). It shows three boxes representing the President's Science Advisory Committee, the Office of Science and Technology, and the Federal Council for Science and Technology. It would be helpful to have more explicit definitions of the respective functions of these offices. Especially, what is the difference between the Council and OST? Is it necessary to have three such groups operating between the President and the executive departments shown at the bottom of the charts? Why?

The Federal Council is composed of policy level officers of the Federal agencies having research and development functions. Such functions are widely dispersed among the Federal agencies, and there is a need, consequently, for the exchange of information and the coordination and correlation of their programs and procedures. The FCST, therefore, is the principal mechanism for developing interagency articulation of Federal science activities. It is concerned primarily with resolving issues of a multiagency nature by means of the type of coordination which one achieves through detailed discussion of shared problems. It leans heavily on the scientific advice of the President's Science Advisory Committee and the National Academy of Sciences. Through various subcommittees and the staffs of the agencies and of the Office of Science and Technology, it examines areas of primary national interest where a concentrated effort and Government-wide approach is deemed essential, either because of the magnitude of the activity or because of the multiplicity of agencies involved. Whole scientific fields are reviewed with respect to scientific expectation and national goals as well as to possible gaps and overlaps.

The Office of Science and Technology, on the other hand, is a relatively small "staff" group charged with assisting the President in securing the coordination of Federal scientific and technological activities and in evaluating the scientific research programs undertaken by Federal agencies. OST is concerned with national policies of science and technology, both the role of science in policy and the complementary role of policy with respect to science. It also provides staff assistance to the President's Science Advisory Committee, the Federal Council for Science and Technology, and the Science Adviser. An important role of the Director of OST is to serve as an especially significant communications link between the executive branch and the Congress.

The President's Science Advisory Committee is comprised of leading scientists and engineers from outside the Government who review the status of important fields of science utilizing as appropriate special panels whose total membership includes several hundred scientists from all over the country. This arrangement not only brings to bear on Government problems the wisdom and experience of all these individuals, but also is an effective mechanism for communication among scientists in the universities and industries actively engaged in research and development and between them and the Government, thus providing an important clearinghouse for information and ideas. PSAC provides a nongovernmental balance to the advice

and responsibilities of FCST and OST. I believe that each of these three mechanisms performs essential tasks which are both different and complementary. Together they provide valuable assistance in the coordination and evaluation of the widely ranging and necessarily different research and development activities and programs of the Federal Government. They should not be considered as "operating between the President and the executive department," and we tried to design the chart to which you refer (No. 3) so as to avoid this interpretation.

Federal science activities are very varied and undertaken by more than 25 different agencies. Each of the groups listed, I believe, serves a useful function in making these activities more effective.

B–5. Most of the data on the charts appears to be for fiscal 1963. Is there later data which might show significant changes?

Three charts in the presentation we made on June 23–25 refer to 1963. These are the transfer tables for research and development (chart 5) and basic research (chart 7) and a related bar chart on sources of funds for basic research, applied research, development, and R. & D. plant (chart 4) which is derived primarily from transfer table data. Updated tables for 1964, for charts 5 and 7, are not yet available because these transfer tables are based on reports of expenditures by performers of research and development, and survey totals for 1964 on intramural performance of components of research and development at the three non-Federal sectors are not yet in. (See also our response to questions C–8 and C–9.) The "Federal Funds" series of reports, of course, provides forward data on Federal intramural performance; but this is not a sufficient basis for updating a transfer table.

Preliminary estimates from the ongoing 1964 surveys of industry and the universities are expected to become available in the late summer and fall of 1965. It will then become possible to construct transfer tables similar to those in charts 5 and 7 and to establish national totals on expenditures during 1964 for the performance of basic research and research and development. Because the 1964 university survey is the first one in that sector since 1958, significant changes may show up there, but as of August 1, 1965, the returns on hand do not permit a prediction on this.

(See also C–8; C–9.)

*B–7. You also said, "Consideration of this problem will form an important part of a study * * * to be carried out this summer by a panel of the President's Science Advisory Committee." Will this study be made public? What similar studies have been conducted by NSF?*

I understand that any firm conclusions, findings, and recommendations of the President's Science Advisory Committee summer study now in progress will be published. However, Dr. Brooks and his coworkers on the study look upon this current effort as only the first of a number of investigations required before the complex problems to which they are addressing themselves can be understood in sufficient depth so that effective policy can emerge. The work being done this summer will undoubtedly prove helpful in several respects—but one of its main contributions will probably come from the group's recommendations on additional ways of understanding the various policy implications regarding the Federal support of academic research.

The main concerns of the PSAC summer study have, of course, in one fashion or another, been the subjects of continuing study by the Foundation. Most of these have taken the form of staff studies and many are currently in progress. It is no exaggeration to say that the summer study as conceived could not be conducted in the absence of fundamental information resulting from surveys, studies, or compilations of data published by the Foundation and a number of NSF unpublished studies and staff papers. Among the NSF published materials, just to cite a few by way of illustration, are such items as "Federal Funds for Research, Development, and Other Scientific Activities," "Investing in Scientific Progress," and "Scientific and Technical Manpower Resources."

NSF studies dealing with such subjects as the numbers of faculty members and graduate students, current and projected, the structure of support for academic research, Federal and other sources of support of graduate students, and the problems and issues relating to postdoctoral work are all immediately relevant to the topics of the summer study. So are NSF unpublished data on projected academic needs for facilities and information derived from a study still in progress of Federal support of academic research and education in the sciences by agency and by individual institution and classes of institutions.

One key question being examined in the summer study is the rate of increase required in the Federal funding of academic research, science facilities, and graduate education in the sciences. In connection with this subject, I may note that NSF is currently providing support for a study designed to develop a growth model for academic institutions. Another study bearing directly on that subject is now being initiated by the Foundation's staff. The first phase of this activity is designed to determine the feasibility of constructing a model showing the interactions among the factors relevant to Federal financing of academic research, facilities for science, and graduate education in the sciences. This first phase is scheduled to be completed by the close of October.

(See also E–15.)

B–8. To what extent is NSF obliged to accept recommendations by the President's Science Advisory Committee? Since the President's science adviser chairs PSAC, does this imply that NSF policies and programs devoted to this question are really being established by the Chairman of PSAC (who is also Director, Office of Science and Technology)?

There is no legal obligation on the Foundation to accept recommendations made by the President's Science Advisory Committee. On the other hand, the President's Science Advisory Committee is made up of outstanding scientists and its views are entitled to the highest consideration. The fact that the Chairman of PSAC is also the Director of the Office of Science and Technology does not, in any way, imply that the Chairman establishes NSF policy, although, of course, his opinions carry great weight with us. In fact, of course, the Director of the Office of Science and Technology advises the President and should the Foundation be in disagreement with the Director of the Office of Science and Technology, the matter can be placed before the President for decision. Insofar as determination of the

NSF budget is concerned, the Bureau of the Budget and the President's science adviser take active roles. However, the final decision is that of the President. The President's Science Advisory Committee plays no part in this process except insofar it may make recommendations with respect to special needs in science.

B-9. What policy guidelines has the National Science Board promulgated, and how are they implemented by the Foundation?

From its very beginning, the Board has devoted a great deal of thought and discussion to a determination of the policies and programs of the Foundation. After the Board, pursuant to its statutory authority to make policy for the Foundation, has approved a program, it is implemented by the Director as chief executive officer.

The Board has also, from time to time, developed policy guidelines of broader application. Thus, in 1954, the Board established a policy for the Foundation regarding loyalty evaluation as related to the support of unclassified research. Subsequently, a special committee of the National Academy of Sciences established at the request of the executive assistant to the President, recommended a similar policy following which the White House requested all Federal agencies to follow the general guidelines proposed.

Under the terms of the report of the Rubber Producing Facilities Disposal Commission, the Foundation was charged with assuming responsibility for the Government's synthetic rubber research program and evaluating the future role of the Federal Government with respect to research in this field. In meeting this second responsibility, the Board appointed a special commission to make recommendations to it. The report of the special commission making a number of recommendations was approved by the National Science Board in December 1955, was subsequently endorsed by the Office of Defense Mobilization, and was incorporated in the President's message to the Congress on rubber resources, requirements, and research in April 1956. The recommendations of the commission were subsequently implemented by the Foundation, other agencies, and the Congress. Another policy recommended by the National Science Board involved the provision to appropriate Federal agencies of grant authority to support scientific research and to vest title to research equipment in the grantee or contractor. This recommendation was implemented by the enactment of Public Law 85-934 on September 6, 1958.

Another type of implementation of policy recommendations of the National Science Board is that exemplified by the reports "Basic Research, a National Resource" (1954) and "Government-University Relationships in Federally Sponsored Scientific Research and Development" (1958) issued pursuant to section 3(a)(1) of the National Science Foundation Act. In other instances the National Science Board has endeavored to create national science policies through Foundation programs. Thus, in 1960 the establishment of the institutional base grant program by the Foundation pointed up the need for giving academic institutions more flexibility in their science operations and in 1963 the science development program underlined the need for creating new centers of excellence throughout the country.

At a somewhat different level of concern, the Board has, from its earliest days, dealt in depth with policies which guide the Foundation in administering its research grant programs, its fellowship activities,

the facilities support efforts, and so forth. Whenever circumstances appear to require reassessment of an established policy (or its modification) the Board discusses the matter and either reaffirms the existing policy or decides upon a new policy.

Policies enunciated by the Board are in general implemented through the dissemination throughout the Foundation staff (and throughout the scientific community when appropriate) of any revised or new policy positions enunciated by the National Science Foundation.

B–11. As a former member of the Atomic Energy Commission please Director?

Where the action is covered by established policy, the Board has delegated to the Director the approval of fellowships, and of grants and contracts except those which call for extremely large expenditures. The delegation permits the Director to approve or revoke any grant, contract, or other arrangement which (*a*) has an average annual rate of expenditure of $500,000 or less and totals less than $2 million, or (*b*) is for the construction of a facility and amounts to $1 million or less.

The Board has also delegated authority to the Director for the provision of funds for approved programs, such as the academic year institutes program, the Antarctic research program, and the science information exchange program, even though the amount of an individual grant may exceed the limits normally applicable. These, for the most part, are continuing activities, and the Director keeps the Board informed by reporting on progress and expenditures. However, no new programs are undertaken without the approval of the Board.

The Director has also been delegated authority to take final action in relation to grants, contracts, or other arrangements during fiscal years 1966, 1967, and 1968 in respect of providing support for oceanographic research vessels, up to a total of $20 million, without regard to the annual rate of expenditure in an individual grant.

As a result of such delegations, only approximately 50 individual actions are passed on by the Board each year.

B–11. As a former member of the Atomic Energy Commission please compare the functions and responsibilities of the AEC to those of the National Science Board in regard to such matters as agency management, national policymaking, agency policymaking, and internal organization.

The Atomic Energy Commission is a quite different kind of body than the National Science Board. The Commission can more meaningfully be compared to the National Science Foundation as a whole. Whereas the Commission has the full authority and responsibility of the agency, in the Foundation there are shared between the Board and the Director.

The chief executive officer of the Commission, the General Manager, is appointed by and is responsible wholly to the Commission; in contrast, the Director of the Foundation is appointed by and must be responsible to the President, although his actions are subject to policies established by the Board and in many major areas require specific approval of the Board.

The five members of the Commission are full-time Government employees who are forbidden by statute from engaging in any other

business, vocation, or employment. The National Science Board is composed of 24 part-time members and the Director. The part-time members are occupied on business of the Foundation only intermittently; their major occupations and responsibilities lie outside the Government. Because of its part-time nature the Science Board cannot be as conversant with or play as intimate a role in the operations of the agency as does the full-time Atomic Energy Commission. By the same token the Board, with its strong roots in the scientific and academic communities, forms a considerably more independent body than does the Commission, which is a wholly integral part of the executive branch. This independence is enhanced by the fact that, in contrast to the Chairman of the Commission who is designated by the President and serves as such at the pleasure of the President, the Chairman of the Science Board is elected by the Board from among its members.

Below the level of their chief executive officers, the Commission and the Foundation have similar structures, the differences being appropriate to their missions.

The Atomic Energy Commission is the dominant agency in the formulation of national policy in atomic energy matters, although it shares its responsibility in the military sphere with the Department of Defense and in the international field with the State Department. Moreover, the Federal programs in its area, including the development and production of nuclear weapons, are almost entirely effectuated by the Commission itself. Its licensing and regulatory activities add to its dominance in the field.

In addition to formulating policy for the Foundation, the Board recommends broad Federal policies relating to basic research and education and through its statistical surveys and studies of national resources for science the Foundation makes a further contribution to national policy formulation in a broad sense. However, the Board cannot itself determine those general policies; moreover, the Foundation plays only a part in implementing policies in its sphere of activity as it is but one of several agencies involved. Thus, it might be said that, whereas the Atomic Energy Commission has concentrated responsibility and control in a particular sphere and implements almost all the Federal program in that sphere, the Science Foundation has a shared responsibility in a much broader area.

B–12. NSF consultants or members of advisory panels are normally appointed under the authority of section 15(a) of the NSF Act which does not limit the per diem such members may be paid. Other Government agencies do have a statutory maximum per diem rate (for example, DOD is limited to a maximum of about $83 and NASA to $100). What per diem rate does NSF pay its consultants appointed under the authority of section 15(a)? Is there any reason why a statutory maximum rate should not be placed in the act? What amount would you recommend?

The NSF pays its consultants appointed under the authority of section 15(a) up to $75 per diem except under unusual circumstances; up to $100 per diem has been authorized in a few such unusual cases, but only after each specific case has received my personal approval. Within the past year only two consultants (out of more than 500) have been paid at the $100 per diem rate. We feel that it would be

undesirable to put a statutory maximum rate in the act because as matters now stand we have greater flexibility for action which can be utilized if the circumstances warrant. We are somewhat on the conservative side in the fees we pay our consultants and such actions are always taken in a judicious manner. Quite a few of our consultants serve without compensation on the basis that it is a privilege for them to participate and that they feel they owe this contribution to science. If it is felt that a statutory maximum rate should be set, I would recommend $100 per diem at the present time.

B-13. Members of the National Science Board, special commissions, division committees, and the Science Information Council are limited by statute to $50 a day. Isn't it poor policy to pay members of advisory panels more than members of the Board? Should the per diem allowance for members of the National Science Board be increased? To what amount?

The divisional committees have been abolished by Reorganization Plan No. 5 of 1965 and only two special commissions have been created. Of course, NSF will continue to seek the help of "advisory" committees in the various fields of its interest, but these will not necessarily bear a 1-to-1 correspondence to the Foundation's divisions. Thus, the question of payment for divisional committee members requires no answer. The main question, therefore, is whether it is poor policy to have Board members and members of the Science Information Council limited to $50 per day. While these appointments are not accepted with any thought of the amount of recompense (and it almost certainly has no bearing on the caliber of persons who accept appointment), nevertheless, if other changes are made in the National Science Foundation Act, it would seem desirable to remove the statutory limitation on the per diem rate for members of the Board, the Science Information Council and special commissions. No special legislation for this purpose is recommended, however.

C. Support of Basic Research

B–6. In discussing the need for increased support, you testified on June 25 (p. 4 of your statement), "We find that each year we need an overall increase of 15 percent or more in support of research at academic institutions merely to maintain a constant relative level of research effort." On what base is this 15 percent estimated? Does not a constant percentage increase each year represent exponential growth? What fraction of this 15 percent should come from NSF?

E–7. Does the 15-percent growth figure apply also to the support of student education? Does it apply to facilities?

E–6. Will the need for a 15-percent annual growth rate in NSF support for basic research in the universities increase, decrease, or change in any foreseeable trend?

C–6. What has been the actual rate of growth in the Foundation's support of basic research for the last 5 years? What is your projection for the next 5 years?

The 15-percent growth factor for academic research mentioned in the quoted statement was also discussed in the NSF budget submission to the Congress for fiscal year 1966. This growth rate refers to the total *Federal* support of research in universities and colleges proper, rather than to that of *NSF* alone. As I noted in my June 25 testimony, this growth in support can be associated with two factors. The first is the increasing numbers of faculty members and graduate students as colleges and universities expand their enrollments to meet the national needs. It is estimated that the annual increase will be some 8 or 10 percent for the next decade. The second is the increasing cost of research per scientist, primarily because the increasing complexity of research requires the use of more sophisticated equipment and of additional supporting personnel. The annual increase in cost of support per scientist is estimated at some 5 to 7 percent.

Thus, combining these two factors, it was estimated for the fiscal year 1966 that an overall increase of at least 15 percent in total support of research in academic institutions would be needed merely to maintain a constant relative level of research activity in those institutions. A substantial part of this increase was estimated to be provided by Federal agencies that have specific missions to perform, although the budgetary decisions of these agencies for the support of research are quite properly made with primary reference to their mission requirements rather than to the specific need to support science in colleges and universities and may well fall short of a 15-percent increase. (See also our response to questions A–8, C–1, E–9.) A review late in (calendar) 1964 of the budgets being proposed for fiscal year 1966 by these agencies showed that they provided for considerably less than the desired 15-percent increase in the support of academic research. Because of the Foundation's responsibility for the strengthening of basic science and science education, the Presi-

dent adopted the concept that the Foundation's fiscal year 1966 budget for academic research should be sufficiently large to assure the necessary 15-percent increase in overall Federal support of basic research in academic institutions.

Following this principle, the President's budget contained a request for $191 million for basic research project grants, an increase of approximately $70 million above the funds available in fiscal year 1965. The Foundation's appropriation for fiscal year 1966, judging from the actions to date by the Congress, would allow us to assign for this purpose an increase of a little more than half that amount, or about $40 million.

The "15 percent growth figure" of question E-7 is assumed to be the same figure dealt with in question B-6 and in the above discussion. Some of the arguments which lead to the finding that research at academic institutions will need increased support of at least 15 percent annually apply also to the problem of student education and the need for facilities, but others are different so that the needs for growth are not equivalent in all three cases.

Demographic factors lead to increased numbers of graduate students in science and engineering in our universities. This increase is one of the elements used in estimating the future needs of academic research. Although we can project with some confidence the increase of graduate enrollments, we have not yet been able to make any sound estimates as to the increased costs associated with the larger graduate student population.

Because there is a definite correlation between those factors which determine future student costs and those which are associated with academic research, it seems fair to assume that the annual rate of growth in these two areas will be approximately the same. There is no reason to think that the Federal role in supporting graduate students will diminish as the student population increases; there will very likely be some increase in the fraction of student education costs (at the graduate level in science and engineering) borne by the Federal Government. The recent increase in size and scope of the fellowship program funded by the U.S. Office of Education will, of course, help significantly in the task of assuring adequate support levels for advanced students. (In this connection, see also our response to question E-19.)

As we have pointed out in our response to questions D-3, D-4, and D-5, it is useful to divide the consideration of facilities into two parts. Doing so enables us to focus on major research facilities (oceanographic research vessels, particle accelerators, and the like) as one important area and on "space" (new or refurbished research laboratories in the main) as another.

In the case of major research facilities, one cannot assume as tight a coupling between increasing student population and rising costs, as can be reasonably postulated for academic research and for student education costs. Here, however, the output of the educational system must be considered: each year there are turned out more highly qualified young scientists. The rising numbers of research scientists will determine the nature and scale of the research opportunities in which the United States must invest in the national interest. This obviously will require a much larger investment in "hardware."

(I have used the word "investment" advisedly, for I sincerely believe that the tax funds going into such major research facilities can more properly be referred to as "investments" than as "expenditures.")

The analysis of probable trends in costs of major research equipment and facilities leads to a further difficult-to-project factor. It is easily demonstrated that research instrumentation, in general, is becoming more costly all the time—but this fact is observed most strikingly when one looks at the successive generations of radio-telescopes, large-scale computers, particle accelerators, and comparable major items. The cost of the 200-Bev. accelerator now being planned by AEC will probably be of the order of the combined costs of all the accelerators built in the United States up to this time. This may be an extreme case, but it illustrates the point I wish to make. Because of this problem, and because major equipment items will probably continue to require special consideration by the executive branch and by Congress—often on a case-by-case basis—we have not been able to find any way of estimating what the annual rate of increase due to this type of cost increase might be over the next few years.

In our response to questions D–3, D–4, D–5, and D–8, we have discussed the problem of providing additional or refurbished laboratory space for graduate students and their mentors. Here, therefore, I will simply point out that the "growth figure" associated with the increasing needs of this nature is also correlated with the growth of graduate students, as is the growth figure for academic research and for student education. But, in this case, it would seem to me more important to look at the total (absolute) needs that we face than at the question of annual rates of increase of funds. If the estimated $4.3 billion needed in the 1962 to 1973 decade is a reasonably accurate estimate (see D–8), and if the institutions continue to assume (as they mainly have done) that they will have to look to the Federal Government for roughly half of these building needs, the total needed from the various agencies now providing such help will have to rise very substantially above present levels in order to come close to meeting projected requirements.

I do not see any reason why the 15 percent growth factor should be decreased in the near future. But I must make it clear that the 15 percent figure was a "best estimate," as previously described, for meeting the requirements for fiscal year 1966. It seems clear that the trend for an increasing requirement will remain fairly constant, but what is not so clear is the assessment of that trend in terms of a specific annual increment. In my statement of June 24, 1965, I touched on this point as follows:

> Because we recognize fully the imprecise nature of this 15-percent estimate, constant efforts are being made to discover better ways to determine these future needs. For example, consideration of this problem will form an important part of a study of basic research, particularly at the universities, which will be carried out this summer by a panel of the President's Science Advisory Committee. This study is regarded as a significant step in a continuing effort to understand and analyze these problems. The Foundation is partaking in and is providing a major component of the staff work for this effort.[1]

If the National Science Foundation is to be expected and allowed to compensate for "shortfalls" as other agencies drop below the estimated minimal 15-percent annual growth rate, budgetary increments in ex-

[1] See also the response to question B–7.

cess of 15 percent almost surely will be required for NSF for several years to come. This annual percentage increase does represent an exponential growth. However, in due course, the demographic factor of relative rate of growth of "student load" will drop, and that of academic research needs will do the same. But this is not likely to happen for at least another 10 years.

With reference to the Foundation's growth in basic research support, the following table reflects the growth in levels over the last 5 years of NSF support of all basic research (including research project grants, national programs, national research centers and minor contributions from other NSF activities).

NSF obligations for basic research [1]

[In millions of dollars]

	Amount	Relative increase
Fiscal year 1960	$68.4	
Fiscal year 1961	77.3	13
Fiscal year 1962	105.5	49
Fiscal year 1963	144.0	37
Fiscal year 1964 (estimate)	164.8	14
Fiscal year 1965 (estimate)	203.9	24

[1] Federal Funds for Research, Development, and Other Scientific Activities, vol. XIII.

From this table it can be shown that the average annual rate of increase of basic research support by the Foundation over these 5 years was 24.8 percent.

In very recent years the support of basic research through many Federal agencies has not been increasing at a rate which many consider necessary to insure adequate support of basic science. Obviously, this is a crucial consideration with respect to the Foundation and its future budgetary levels. Because of the uncertainty surrounding the aggregate support likely to be available from other agencies, it is very unclear what our projections for basic research should be or can be in the years just ahead. Any projection is especially hazardous when a part of the forecasting is dependent upon the ability of other agencies to meet increasing requirements for basic research. On the basis of a continuation of the present rate of increase, it is estimated that the Foundation's levels of support for basic research will rise from about $255 million in fiscal year 1966 to approximately $620 million in fiscal year 1970.

A–8. Are too many Federal agencies today involved in supporting basic science grants and science education? Is there significant duplication here? Might not the Foundation assume a more central, if not exclusive, role in this regard?

C–1. In your testimony on June 25, you stated: "As time moves on, I see NSF accepting a heavier financial responsibility on behalf of all Federal agencies for an expanding basic science. I believe that all agencies should and will continue to support basic research, as they now do, but NSF is likely to be thought of as the logical agency to meet a major fraction of new and expanding requirements." Are these new and expanding requirements related to national goals and agency missions? If so, should not

the Federal agencies other than NSF continue to expand support for basic sciences?

E-9. Could you furnish fiscal year 1965 data on the total amount of basic and applied research conducted in universities proper and sources of funds? Also, could you compare the trends of growth in the support with growth in faculty and graduate student enrollments?

Support for basic science and for science education is provided in significant amounts by 13 Federal departments and agencies. In some instances, when the research program of an individual scientist is of special pertinence to the mission interests of several agencies, they may cooperate in supporting the work, i.e., support may be provided from multiple sources. This happens most frequently when none of the agencies is able to assume full support for the project.

However, duplicate (in contrast to multiple) support occurs rarely if at all. There are a number of mechanisms within the Federal structure which effectively control and discourage undersirable duplication. (See our response to question B-14—E-8 for details of these mechanisms.)

The statement quoted in question C-1 was made in the context of our full conviction that the expanding needs and requirements of science are indeed related to national goals and objectives. We believe it is axiomatic that in the direct interests of the welfare of the Nation it is necessary to sustain a strong and vigorous science enterprise. This, in turn, depends on maintenance of a healthy system of collegiate and graduate education in the sciences and of a strong and productive basic research effort in our universities. The training of an adequate supply of future scientists and the continuous production of new fundamental scientific knowledge are certainly important national goals. Clearly the National Science Foundation must play a central role in helping to reach these goals.

But also, as has been amply demonstrated during the past two decades, our universities, which are the principal loci of basic research and education, can help to meet important objectives in the missions of many Federal agencies without disservice to academic responsibilities. This relationship should be encouraged and all Federal agencies should participate in helping to meet the expanding needs of academic research; for it is quite clear that these enlarged requirements are indeed related to specific agency missions as well as to broad national goals.

But we believe that the National Science Foundation, in this context, has a special responsibility because its principal mission is "* * * the promotion of basic research and education in the sciences." Accordingly it must be willing and able to accept those aspects of support of academic science which cannot be fully or appropriately assumed by other agencies because of the relatively limited nature of their assigned roles. Only in this way can the Foundation live up to its charge of assuring the health and growth of scientific research and education in America.

Accordingly, we believe that each Federal agency should avail itself, to an extent consistent with its mission, of the opportunities inherent in the support of basic research and science education. But we are also convinced that the welfare of the Nation can be served most ade-

quately if, in the coming years, the Foundation is provided appropriations in sufficient amounts to permit it to really assure the health of basic science, including—importantly—academic science in all significant fields.

The amount of research conducted by universities has, of course, increased very considerably during the past decades. Data for fiscal year 1965 on the total amount of research (basic plus applied) conducted in universities proper and sources of funds are available only *on an estimated basis. Estimated* research expenditures (in current dollars) in universities and colleges proper, by sources of funds, fiscal years 1954 and 1965, are shown in table 1.

TABLE 1.—*Estimated research expenditures, universities and colleges proper, fiscal years 1954 and 1965*

Source of funds	Fiscal year 1954		Fiscal year 1965 [1]		Compound annual rate of increase (percent)
	Amount	Percent distribution	Amount	Percent distribution	
Federal Government	$142	48	$1,050	68	19.9
Industry	15	5	60	4	13.4
Universities and colleges	124	41	330	22	9.3
Other nonprofit institutions	19	6	90	6	15.2
Total research funds	300	100	1,530	100	16.0

[1] NSF staff estimates.

TABLE 2.—*Faculty and graduate student growth, 1954–65*

[In thousands]

	Academic year		Compound annual rate of increase (percent)
	1953-54	1964-65	
Instructional staff [1]	140	246	5.2
Graduate students [2]	219	498	7.8

[1] Full-time-equivalent instructional staff for resident degree-credit courses.
[2] Enrollments in degree-credit courses.

It should be noted that these estimates for fiscal year 1965 are based on secondary sources of information, rather than on data reported by universities and colleges on the amounts and sources of their research funds.[1]

As table 1 indicates, research funds in universities and colleges proper totaled an estimated $1,530 million in fiscal year 1965, compared with $300 million in fiscal year 1954. On the basis of these estimates, we conclude that:

Federal Government research support increased at a somewhat higher rate than other sources of research funds during the 11-year period;

In fiscal year 1965 the Federal Government financed 68 percent of the research performed at universities and colleges proper, compared with 48 percent in fiscal year 1954;

[1] The National Science Foundation is currently conducting a survey of scientific activities of institutions of higher education, 1963–64, which will yield definitive information on the total amount of basic and applied research conducted in universities proper, by source of funds. This survey will yield benchmark data that will make it possible to estimate fiscal year 1965 levels of research funding with increased precision.

The relative share of research financed by "other nonprofit institutions" was the same in both years, industry's portion declined slightly, and the relative amount financed by universities and colleges decreased from 41 percent in fiscal year 1954 to 22 percent in fiscal year 1965.

The proportionate increase in total research funds in universities and colleges proper during 1954–65 (see table 2) exceeded the relative increases in the numbers of faculty and graduate students. In comparing research funds with personnel data, however, several points must be borne in mind. One of these pertains to the relative bases upon which these percentage increases are calculated. In the case of research support, it is to be remembered, the support base in fiscal year 1954 was quite low and the annual increases, in terms of percentage, therefore appear high because the sums required to "catch up," as it were, were relatively large compared to the small starting base.

Secondly, it should be noted that in the comparisons made here, research funds are expressed in "current dollars." This procedure does not take into account the decline in purchasing power that occurred during the 11-year period. (We are making efforts to determine the magnitude of the proper factor to use in determining the "purchasing power" of research dollars at each given point in time—but this proves to be a particularly difficult problem.)

B–14. Witnesses have mentioned that research programs of the different agencies are coordinated in a variety of ways. What are these coordinating mechanisms? Give examples of the coordination among NSF, NASA, NIH, AEC, etc.

E–8. What mechanism exists by which the Foundation can identify existing or proposed support of other Federal agencies to any particular university?

We use a number of different mechanisms "to correlate the Foundation's scientific research programs with those undertaken by individuals and by public and private research programs with those undertaken by individuals and by public and private research groups.[1] Among these mechanisms are several which help us to identify existing or proposed support by other Federal agencies: (*a*) participation of NSF representatives on interagency committees and panels; (*b*) personal contacts between NSF representatives at the division and program levels and their counterparts in other Federal agencies; (*c*) exchange of proposals and information about proposals on a routine basis; (*d*) reports of Federal agencies concerning grants or contracts awarded; (*e*) reports, bulletins, announcements, and other published or unpublished financial statements of particular universities; and (*f*) surveys of universities and colleges conducted by the National Science Foundation, the U.S. Office of Education, and other Federal or private organizations. Each of the above-mentioned mechanisms is described in the sections that follow. In addition, there is provided at the end of the answer to this question a listing of groups which, in one way or another, are involved in the coordinating process.

A. *Committees and panels.*—Members of the Foundation's research divisions participate in numerous interagency meetings related to particular disciplines of missions. Staff members attending such meetings obtain information regarding current and future programs and

[1] Quoted from sec. 3(a)(6), National Science Foundation Act of 1950.

plans of other agencies. These committees and panels are constituted as part of basic legislation, by executive order, or by joint action of the departments and agencies.

Although there are many of these formal, organized groups which help effectively to coordinate the research programs of different Federal agencies, I shall give only two illustrative examples of their nature and role.

(1) Research in oceanography is coordinated through the Interagency Committee on Oceanography, a Committee of the Federal Council. This Committee, which is chaired by the Assistant Secretary of the Navy for Research and Development, includes all of the Federal agencies which either support oceanography or undertake programs in-house. The Committee reviews annually the proposed budgets and programs of the various agencies and recommends appropriate changes so that the total Federal activity represents a national program.

(2) Another important example of formal cooperation is provided by the Interagency Coordinating Committee on Antarctica, which consists of staff-level representatives of the Departments of State, Defense, Interior, and Commerce, the National Science Foundation, the U.S. Information Agency, the Arms Control and Disarmament Agency, and the Bureau of the Budget. This Committee meets at predetermined intervals to discuss problems of mutual concern and to coordinate activities.

In planning and coordinating the U.S. scientific program in Antarctica, the National Science Foundation has been directed by the Bureau of the Budget to coordinate with the Department of Defense. The Foundation's Office of Antarctica Programs and the U.S. Naval Support Force, Antarctica, are jointly involved in planning the annual effort in Antarctica. A high-level Antarctica Policy Group, representing NSF, DOD, and State reports to the President on antarctic international problems. During the operational period of the antarctic summer, Foundation staff members represent and coordinate the scientific program requirements in the field with the naval commanders responsible for providing logistic support.

B. *Personal contact among agency staff*.—Under informal arrangements, staff members of the Foundation at the division and program levels attend reviewing panels of other agencies as observers. For example, staff members of the NSF genetic biology program sit in on discussions of the NIH Study Section reviewing proposals in that field. A different example is the Interagency Solid State Administrators Group—an informal group which meets bimonthly. In addition to discussing the research programs supported by the various agencies, the Group considers such matters as: ways of reducing possible multiple support of some grantees; a uniform coding system to assure a higher quality of statistical information; and a system whereby appropriate agencies can more efficiently exchange information concerning proposals. A central file of all grants to universities in the general materials field has been activated.

Another example of purposeful coordination is the Interagency Group for Research on Information Systems (IGRIS)—an informal organization for administering research programs in the field of information systems. The group meets regularly to: exchange in-

formation concerning programs, plans, progress, trends, and funding; discuss mutual problems of scientific contract supervision and administration; achieve voluntary coordination of activities by reducing duplication of effort, noting gaps wherein greater effort is desirable, and to make appropriate recommendations when necessary.

Among these coordinative mechanisms, clearly one of the most important is direct person-to-person communication—usually by telephone—between program administrators. Such communication between program directors in different Federal agencies provides assurance that the administrators of programs in various fields of science are well informed on which groups in Government are supporting particular kinds of research and which groups have special interests in certain subfields of a scientific discipline.

Thus it is relatively easy to avoid undesirable overlap of support in terms of either kinds of research or levels of funding. At times mutual agreements are developed which result in coordinated grants by two or more Federal agencies. For example, at the Massachusetts Institute of Technology, a Foundation grant of $375,000 is one important element in a coherent, research-support plan for the Center for Communication Sciences. This center, now in its seventh year, has been supported jointly by NSF, DOD, NASA, and private groups as well.

C. *Exchange of proposals and exchange of information on a routine basis.*—This mechanism was established primarily to identify duplication in proposals to several agencies. However, the exchange of information also involves data on the types, amounts, and other characteristics of the support of other Federal agencies. For example, the Division of Mathematical and Physical Sciences exchanges with a number of other Federal agencies monthly reports on proposals. The Division of Biological and Medical Sciences also collects data from other Federal agencies covering the life sciences. The task of collecting and making information available on current projects is being performed by the Science Information Exchange (SIE). The Science Information Exchange has a file on more than 70,000 research projects in the biomedical, the physical, and the social science fields. These include projects sponsored both by the Federal Government and by other organizations. Among the services that can be provided by the SIE is the listing of federally supported research projects and proposals of particular universities.

The following specific examples will illustrate how certain individual proposals were the subject of close coordination between interested and cognizant groups:

1. A proposal for the support of a new building at a major university was submitted simultaneously to the Science Facilities Section of the NSF and the research facilities program of NIH. After a thorough review by each agency it was agreed that the NIH grant would be for $425,000 and that the NSF grant should total $1,375,000.

2. The Science Facilities Section of NSF received proposals from three universities, each of which requested funds for the construction of housing for accelerators to be furnished by the AEC. On contacting the AEC, NSF learned that only one accelerator award was to be made and AEC agreed to inform NSF when a decision was made as to the recipient of the award. The proposals to house an accelerator

were held until the AEC decision was made, and then (after carrying out an appropriate review) NSF made one facilities grant.

3. The National Science Foundation was requested to provide funds for the development and construction of an electron microscope capable of operating at the ultimate level of theoretical resolution. This achievement should make possible direct observations of molecular structure and provide fundamental information on important biophysical and biochemical processes. NSF funds were too limited to permit full support for this project, but it was possible to assist this research by means of joint support from the National Science Foundation and the National Institutes of Health.

4. Following the Alaska earthquake of March 27, 1964—assessed as one of the most severe of modern times—President Johnson requested his Science Adviser to undertake a comprehensive scientific and technical study of the earthquake and its effects. Dr. Hornig, in turn, requested that the National Academy of Sciences set up a committee to undertake a survey of earthquake effects, to coordinate reports, and to prepare a summary of the scientific, technical, and economic aspects of the disaster. Responsibility for the biological studies was assigned to an oceanography subcommittee which met in December 1964, at the California Academy of Sciences for the purposes of formulating plans for carrying out a biological investigation in the earthquake area. Funds to support a field party to carry out these studies were awarded by the National Science Foundation and the Atomic Energy Commission.

D. *Reports of Federal agencies.*—Federal agencies maintain records and issue reports of various types and in varying detail on grants or contracts awarded. These reports typically contain information describing the type of award, amount, duration, and the name of the principal investigator. Where additional information on the award is needed, it can be obtained by contacting the appropriate official of the awarding agency.

During the past 2 years, Federal agencies have been requested by the Congress to supply data on the amounts of grants and contracts awarded particular universities and colleges on at least two different occasions. For the May–June 1964 hearings of the House Subcommittee on Science, Research, and Development, 5 agencies (AEC, DOD, NASA, NIH, and NSF) were asked to supply data on the 100 universities and colleges proper receiving the largest amounts of awards, and 3 agencies (Agriculture, Commerce, and Interior) were requested to supply the names and amounts of grants and contracts awarded to the 25 institutions receiving the largest amounts. In late 1964, Senator Ribicoff requested that five agencies (AEC, DOD, HEW, NASA, and NSF) provide data on obligations for research, training, and facilities, by educational institution, for fiscal years 1963, 1964, and 1965.

E. *Reports of universities and colleges.*—Virtually all universities and colleges publish financial statements covering their operations during specified fiscal periods. Such financial statements constitute a source of information on all sources of income, including income received from Federal agencies. Even where an institution does not publish publicly financial statements covering its operations, copies of

such statements can usually be obtained upon request. Because such reports cover different periods, are made available at different times, and are in other ways noncomparable, they are of limited usefulness as sources of "national" data; they are nonetheless quite useful as a means of obtaining more or less detailed data on a specific institution.

F. *Surveys of universities and colleges by the National Science Foundation, the U.S. Office of Education, and other organizations.*—The National Science Foundation has conducted a number of surveys of universities and colleges to obtain information on the allocations of scientific and engineering resources. Such surveys obtain data on all sources of support for scientific activities for which information is requested, including support provided by individual Federal agencies. The Foundation is currently engaged in a survey of scientific activities of institutions of higher education, 1963–64, which will provide data on Federal support of R. & D. performance; capital expenditures for research, development, and instruction in the sciences; and expenditures for education in the sciences.

The National Science Foundation conducts an annual survey of Federal funds for research, development, and other scientific activities. This survey collects data from Federal agencies on extramural obligations going to universities and colleges for research, development, and R. & D. plant, but does not request separate figures for each institution.

The U.S. Office of Education conducts a biennial survey of financial statistics of institutions of higher education. A survey covering fiscal year 1964 is currently in progress. This survey collects data on current-fund income and plant-fund income of all universities and colleges, by source of funds. Data reported by individual institutions in this survey are not published.

A number of private organizations also conduct periodic surveys of universities and colleges that yield data on sources of income and expenditures for research, education, and other activities of individual institutions.

The following listing of boards, committees, panels and councils provides a rather wide sampling of the organized research coordinating mechanisms on which Foundation staff serve as members, representatives, observers, or consultants—and which are of direct relevance to the coordination of Federal activities in science and technology. This list (intended to be illustrative only) is presented according to the following headings:

(1) Beneath the heading "Departments and agencies"—and under the names of the agencies—we have listed those groups that are—

(*a*) Wholly or primarily "internal" to a given agency, but whose meetings are attended by NSF observers or "liaison members," and

(*b*) Interagency in character, but normally chaired by a representative of the agency under which the group is listed.

(2) Under "Executive office groups" we have listed a number of committees, councils, etc., which are closely associated with one or more of the units serving as staff to the President.

DEPARTMENTS AND AGENCIES

Department of Commerce:
- Federal Committee for Meteorological Services and Supporting Research.
- Interdepartmental Committee on Applied Meteorological Research.
- Interagency Committee for International Meteorological Programs.

Department of Defense:
- Coordinating Committee on Science (ODDRE).
- Defense Science Board.

Department of Health, Education, and Welfare:
- National Institutes of Health:
  - Health Research Facility Council.
  - Interdepartmental Advisory Panel for the National Center for Health Statistics.
  - National Advisory Allergy and Infectious Diseases Council.
  - National Advisory Arthritis and Metabolic Diseases Council.
  - National Advisory Cancer Council.
  - National Advisory Child Health and Human Development Council.
  - National Advisory Dental Council.
  - National Advisory Heart Council.
  - National Advisory Neurological Diseases and Blindness Council.
- Office of Education:
  - Advisory Committee on Graduate Education.
  - Cooperative Research Panel on Curriculum Development.
  - International Cooperation Year, Committee on Education.
  - Federal Interagency Committee on Education.

Department of the Interior:
- Advisory Committee on Atmospheric Water Resources.

Department of Labor:
- President's Committee on Manpower.
- Committee on Specialized Personnel.

Department of State:
- International Cooperation Year:
  - Committee on Science and Technology.
  - Committee on Natural Resources Conservation and Development.

National Aeronautics and Space Administration:
- Space Sciences Steering Committee.
  - Astronomy Subcommittee.

National Science Foundation:
- Interagency Coordinating Committee, Upper Mantle Project.
- Science Information Exchange Advisory Board.
- Advisory Council for Manpower and Education Studies.
- Interagency Coordinating Committee on Antarctica.
- Science Information Council.

EXECUTIVE OFFICE GROUPS

President's Science Advisory Committee:[1]
- International Science Panel.
- Panel on Scientific and Technical Manpower.

Federal Council for Science and Technology:
- Behavioral Sciences Panel.
- Committee on Long-Range Planning.
- Committee on Scientific and Technical Information.
- Committee on Water Resources Research.
- Coordinating Committee on Materials Research and Development.
- Interagency Committee on Oceanography.
- Interdepartmental Committee for Atmospheric Sciences:
  - ICAS–CIO Joint Panel on Air-Sea Interaction Research.
  - Select Panel on Weather Modification.
- Technical Committee on High Energy Physics.

Office of Science and Technology:
- Interdepartmental Energy Study Steering Committee.
- Panel on Education Research and Development.[2]

---

[1] The Director of NSF is frequently invited to attend PSAC meetings as an observer.
[2] This Panel reports to three "Principals": the Director of OST, the Commissioner of Education, and the Director of NSF; it receives staff assistance from OST.

Bureau of the Budget:
Financial Management Advisory Group.
Interagency Committee on Automatic Data Processing.
(See also A–15.)

C–3. What are the fiscal year 1965 estimates in the support of basic research in the universities by Government and by other sources? How does one define "major share"? Will increasing Federal support discourage support by the States and private institutions so that there is less total gain than expected? Should incentives be provided to maintain the current proportion of support between Federal and non-Federal sources?

The fiscal year 1965 estimates for support of basic research in universities and colleges by Federal Government and other sources are shown in the following table:

Estimated expenditures for basic research at colleges and universities proper by source of funds, 1965 [1]

[In millions]

Source of funds:	Colleges and universities proper
Federal Government	$575
Industry	35
Colleges and universities (including State support)	300
Other nonprofit institutions	75
Total	985

[1] Estimates of expenditures are based upon earlier survey data and other sources of information. Estimated expenditures for basic research at Federal contract research centers managed by universities are $145,000,000.

In using the words "major share," I had in mind the existing situation in which the Federal Government supports about three-fifths of basic research conducted at colleges and universities proper. There is no basis for expecting that the proportion of non-Federal support will increase significantly in the near future. Consequently, if academic institutions are to continue to make vital contributions to basic science, Federal expenditures will have to continue to account for about the same proportion of their basic research activities.

There is no persuasive evidence that Federal support has discouraged support by non-Federal sources. On the contrary, a somewhat better case can be made for the view that the Federal Government's commitment to academic scientific research has stimulated support on the part of non-Federal institutions. In fact it has become clear to State and local governments that there are important benefits associated with the growth of academic scientific capabilities. For example, the State of New York recently established a public foundation of science and technology which made grants of about $500,000 in 1964 to support academic research.

The pattern of support of academic research is determined by dynamic forces that are themselves shaped by changing needs, opportunities, and objectives. This pattern of diversified support should be expected to change over time. Federal and non-Federal sources of support represent interacting elements in a dynamic system. The influx of Federal funds into a particular area of research might well alter the pattern of support in that area. Thus, a

private foundation, for example, may divert a fraction of its support from that research in order to stimulate research in a different field.

There is no reason to believe that special incentives should be provided in order to maintain the present ratio of Federal to non-Federal support. In our view it would be unwise to attempt to fix any such ratio. In the years ahead every effort should be made to encourage growth in the whole pattern of support for academic research—both Federal and non-Federal—without regard to any fixed ratio.

C-2. You said also, "there is wide agreement that Federal support of scientific research should expand, particularly in the universities." Does this imply proportionally more basic research should be conducted in the universities? If so, would this mean proportionally less in Government laboratories or in industry? If this is the implication, when and where was this discussed, so as to justify "widespread agreement?"

> *E-4. At the present time approximately 50 percent of the basic research supported by the Federal Government is conducted in universities. Considering our growing Nation and the use of science to serve its needs, do you feel this balance between performers should be changed?*

Perhaps the term "wide agreement" states the situation more strongly than it deserves. Had I used instead the phrase "widespread belief," I now think this would have made the point somewhat more accurately. As will be noted from the comments contained in the NAS report to the Committee on Science and Astronautics entitled "Basic Research and National Goals," the argument for the proposed expansion of basic research support at universities rests in part upon the need to provide research training for increasing numbers of students (and hence for research support of the growing faculty who train them) and on the increasing cost per scientist of performing high caliber research. It is also suggested that support of research in Government-owned laboratories (other than those primarily established to foster academic research) and industrial laboratories should be geared to the needs of the parent organization for research. The level of such support would then be determined in the context of the organization's mission and its available funds. Since the latter criteria are different from those which it is proposed to apply to the universities, there is no reason to think that the proposed increase for the universities would necessarily imply either an increase or a decrease in Government laboratories or in industry.

With respect to those Government laboratories which are highly productive of research results related to the mission of the parent organization (perhaps only in a long-range sense), it is clear that increased yearly support should be provided at whatever rate is warranted by mission needs. Similarly, the level of Federal agency support of basic research in industry should not be tied to the amount of such support in universities, but should be judged on the basis of considerations relevant to the assigned responsibilities of the agencies which support such work.

Therefore, I see no need to recommend that a major change take place in our present pattern of university and nonuniversity performance of basic research. In this regard, however, it is important to recognize that one of the characteristics of a vigorous and productive basic research organization seems to be that it combines the efforts of older, experienced, knowledgeable men and younger men with adventurous and creative minds. Such an organization should also provide an opportunity for men with backgrounds in different but related disciplines to exchange ideas and experimental know-how. These conditions tend to exist naturally at universities. While it is true that they can be created intentionally at a nonteaching laboratory, to do so requires a large and expensive organization. The new staff must either continue to grow or have a deliberate turnover such as that which comes automatically at a university because of graduate students and postdoctoral scientists. Some research efforts—those of a very large and comprehensive nature—simply cannot be appropriately carried out on a university campus. Hence, although we consider participation in research projects by students to be highly desirable, it is not possible to arrange for their involvement in all research efforts. Experiments mounted on large space satellites and probes are illustrative of research projects that must often be carried out at laboratories having little connection with a university.

Inasmuch as Government support of science is committed to the training of manpower as well as to increasing our store of scientific knowledge, we must continue to expend major portions of our research budget at universities.

C–4. How is balance of NSF support determined as between different fields of science disciplines? In this respect, what use is made of the studies of the National Academy of Sciences?

The National Science Foundation has been supporting basic research for a period of nearly 15 years. Decisions as to the distribution of support among the several scientific disciplines are therefore made in the light of a current level of support for each field which represents our cumulative experience. The Foundation constantly receives information from individuals and organizations in the scientific community and from other Government agencies which bears on the adequacy of the support being provided. The Foundation's program directors, each an experienced scientist in his field, are especially sensitive to these "error signals," and make certain that this information is passed through their chain of command to the Director. At the same time information is received directly by the Director and the Board and this too goes into the decision process. It is most important to realize that this process is a continuous one and that continuing efforts are made to improve the distribution.

It is also important to recognize that our decisions are not simply based on response to demand. A conscious effort is made to emphasize those fields where the scientific challenge is greatest and where the time appears to be ripe for major advances. (See also the response to A–17.)

Reports from the National Academy of Sciences are one important "input" from the scientific community. We give them serious consideration in our constant effort to improve our allocation of resources. We have found these reports particularly helpful in identifying needs

for major increases in support for specialized facilities and in connection with the establishment of national centers.

(See also A–15; A–17.)

C–7. A recent change in the language of the appropriation bill for NSF and other agencies provides for cost sharing on research grants, whereas previously there had been a limitation on the amount of reimbursable indirect costs. The question is in six parts:

(a) Do you favor such a change?

In my opinion, the change is desirable. While cost sharing or participation has generally been characteristic in most of the research projects which we have supported, I have always believed that the imposition of a ceiling on indirect costs was not the proper method for achieving cost sharing. University accounting systems differ for a variety of valid reasons and the allocation of costs between the direct and indirect categories therefore follows different patterns at different schools. The limitation on indirect costs has therefore not only been burdensome but inequitable. The removal of the limitation on indirect costs will permit both the Foundation and the universities to implement the cost-sharing principle in a more equitable manner.

(b) Did the universities favor the change?

I do not know whether the academic community was consulted at the time the change was proposed by the House Committee on Appropriations, but university officials have clearly indicated that they certainly favored the removal of the ceiling on overhead reimbursement. Inasmuch as cost sharing was already an established and accepted principle, it is my opinion that the universities would favor the change.

(c) How will this modify the current procedure?

The principal change in procedure will be the identification in a more formal way of the amount contributed by the universities. At the present time their contributions, such as faculty effort for example, are stipulated in the proposals but not always priced out and identified. Should the Congress pass the proposed bill with the cost-sharing requirement included, the contributions of the universities will necessarily be more explicitly shown.

(d) How will the cost-sharing rates be determined?

In the report on the appropriation bill for the Department of Health, Education, and Welfare, where the cost-sharing requirement was first proposed, it was stipulated that the Bureau of the Budget would develop Government-wide guidelines for the implementation of the new requirement. A full response to this question must await the publication of the guidelines.

(e) Will it differ institution by institution or even project by project at the same institution?

The answer to this question must likewise await the publication of the guidelines by the Bureau of the Budget.

(f) Will the change affect grants currently in existence?

It is not intended that the change affect grants currently in existence. It is our intention to implement the requirement as soon as possible after the appropriation bill is passed, and the guidelines are published.

C–8. Chart No. 7 which you presented shows the contribution of the Federal Government to basic research [at universities proper] to be $380 million. The latest figure in this regard from "Federal

Funds for Science" is around $600 million. This seems to be a big difference. Why isn't the later figure used? Could you extrapolate some of the other figures to give a more current picture?

C–9. The figure shown for Federal sponsorship of basic research is $1.06 billion for 1963. What appears to be the same figure in chart No. 8 for fiscal year 1965 is $1.3 billion.[1] *What is the explanation for this discrepancy?*

These two questions refer to both obligations data from "Federal Funds for Research, Development, and Other Scientific Activities" and expenditures data from the transfer table in chart 7. As background to the answers, it may be useful to describe the basis of the transfer table for basic research, 1963,[2] in chart, and, in particular, to indicate how data were obtained for the first line of the table—on Federal financing. (For ease in reference, chart 7 is again presented below.)

The transfer table is designed to show how *much money was spent during 1963* in the actual performance of basic research in the laboratories of Federal agencies, industry, colleges and universities, and other nonprofit institutions, and the *sources of that money.* National basic research totals must be in terms of expenditures since expenditures are the common denominator used to express inputs, public and private, into all activities in our economy. (Obligations are generally used only in Government budgeting.) An expenditures total for basic research or research and development can be related to other data, such as the gross national product or outlays for education; it can also be related to employment in basic research or research and development to work up cost/manpower ratios. Because data on

Source: National Science Foundation, 1964

[1] Chart 8 shows the fiscal year 1965 total as $1.9 billion rather than $1.3 billion.

[2] In general, the same method is employed in constructing the transfer table on research and development in chart 5.

expenditures are required, information in the transfer table is obtained from performers of basic research since we have learned from experience that only performers know in the required detail how much was actually spent in the conduct of basic research during a given period—and from where the money came.

Information on expenditures is obtained directly from the performers of basic research in each of the four sectors by means of surveys: in the *Federal* and *industry* sectors, the surveys are conducted annually; in the *university* and *other nonprofit* sectors, surveys have heretofore been made less often. For these latter two sectors, NSF staff has made estimates for the nonsurvey years, such as 1963, based on earlier survey data and information from secondary sources. (For this reason, we should perhaps have indicated on charts 5 and 7 that certain data represented estimates.)

The basic research transfer table is constructed by entering in a particular column that sector's total expenditures for basic research broken down by sources of the money spent as indicated in a just-completed sector survey, or as estimated from an earlier survey. Thus, for the colleges and universities proper in 1963, staff estimates, made in the light of results of earlier university surveys and related materials from university and other sources, placed the total spent for performance of basic research in academic 1963 at around $690 million. Of this, $380 million was estimated as Federal money, $30 million as industrial, $220 million as coming from the educational institutions' own resources, and $60 million as money from nonprofit institutions such as philanthropic foundations and voluntary health agencies.

The committee compares the expenditures estimate of $380 million, which refers generally to academic year 1963, with the obligations figure of "around $600 million" for fiscal year 1965 in "Federal Funds for Research, Development, and Other Scientific Activities, Fiscal Years 1963, 1964, and 1965," volume XIII, and asks, by implication, why there is a "big difference" between the two. As the statistical summary below indicates, the university expenditures of Federal money differ from the Federal obligations for university basic research because the level of obligations has been rising over the years and the expenditures covered in chart 7 took place roughly *2 years before* the cited obligations were made in 1965. (Federal expenditures lag behind obligations and expenditures by recipients throughout the country lag behind Federal expenditures.)

In general, university expenditures of Federal money in a given academic year should be compared with Federal obligations made during the fiscal years which precede and overlap with the academic year. Thus, the $380 million from the 1963 transfer table should be related to the $370 million and $455 million obligated by the Federal agencies in fiscal years 1962 and 1963.

Federal funds for basic research at colleges and universities proper

[In millions]

	1961	1962	1963	1964 [1]	1965 [1]
Federal obligations for basic research at colleges and universities proper [2]	$281	$370	$455	$534	$604
Estimated expenditure of Federal money for basic research at colleges and universities proper [3]		322	380		

[1] Estimated.
[2] Source: "Federal Funds for Research, Development, and Other Scientific Activities," vol. XIII. Updated figures for fiscal years 1964 and 1965 and new data for fiscal year 1966 appear in vol. XIV, now in press, but this table has been based on vol. XIII to retain consistency with data in our July presentation to the committee.
[3] Source: Unpublished NSF staff estimate for 1962; estimate for 1963 from chart 7.

The committee also asks why the fiscal year 1965 figure of "around $600 million" ($604 million in "Federal Funds for Research, Development, and Other Scientific Activities," vol. XIII) for Federal obligations for university basic research is not used, together with "extrapolations [of] some of the other figures to give a more current picture * * *."

One reason why the Federal obligations figure cannot be used as the basis for an extrapolation of chart 7 has already been stated: the transfer table is based on information from performers or doers of research, not from financiers, and the $600 million in obligations is an estimate from the agencies as financiers.

The second reason why extrapolated transfer tables for both research and development and basic research in 1964 have not been published is that we have felt it unwise to publish a current transfer table unless reported data are on hand for at least Federal and industry performance, which together account for over 85 percent of the performance of total research and development. (As indicated earlier, estimates are made for universities and nonprofit institutions for nonsurvey years.) As of July 1965, surveys of both industry and university research and development in 1964 were still out in the field, with preliminary results expected early in the fall 1965; the results of the 1964 survey of other nonprofit organizations are not expected until the spring of 1966. The preliminary results for these two sectors, together with data already on hand for Federal intramural research and development and basic research, will make it possible to publish preliminary 1964 transfer tables for both basic research and research and development by midfall 1965.

In answer to question C–9, which compares data in charts 7 and 8, it is clear from the above discussion that in chart 7 the figure of $1.06 billion represents Federal money actually spent in 1963 throughout the economy in the performance of basic research, as best as we can estimate this from surveys and secondary sources. On the other hand, the Federal totals in chart 8 represent obligations for basic research made by the agencies during a series of fiscal years ending with fiscal year 1965. These obligations found (or will find) their way into actual basic research expenditures by Federal and non-Federal organizations only over a period of years. To clarify this phasing, the summary below compares obligations for the five most recent fiscal years presented in chart 8 with the total of $1.06 billion for 1963 from chart 7.

Total Federal funds for basic research

[In billions]

	1961	1962	1963	1964 [1]	1965 [1]
Federal obligations for basic research—all sectors (chart 8) [2]	$0.80	$1.08	$1.36	$1.63	$1.88
Estimated expenditures of Federal money for basic research—all sectors (chart 7) [3]		.91	1.06		

[1] Estimated.
[2] Source: "Federal funds for Research, Development, and Other Scientific Activities," vol. XIII. Updated figures for fiscal years 1964 and 1965 and new data for fiscal year 1966 appear in vol. XIV, now in press, but this table has been based on vol. XIII to retain consistency with data in our July presention to the committee.
[3] Source: Chart 7 and "Reviews of Data on Science Resources," No. 4.

While no one-to-one relationship can ever be established between the two sets of numbers, it appears, from the table, that the $1.06 billion spent in 1963 by performers of basic research could be traced back, in part, to Federal obligations made in fiscal year 1962 or even earlier, as well as in fiscal year 1963.

In general, the total Federal obligations for basic research, in a given fiscal year, are not likely to be at the same level as actual expenditures for basic research carried on all over the country during about the same period of time, because of the lag in time between Federal obligations and the spending of the funds by recipients. In a period, such as the present, when obligations are rising, expenditures by recipients are likely to lag behind agency obligations.

It is possible to give estimates of the distribution of Federal obligations for basic research in fiscal year 1965 (by performer), basing the estimates on the information for that fiscal year reported by the Federal agencies for the survey which resulted in the publication of "Federal Funds for Research, Development, and Other Scientific Activities," volume XIII, published by NSF last month. The following table summarizes these estimates:

[In millions of dollars]

Performer:	*Estimated obligations*
Federal Government	$361
Industry	423
Universities and colleges:	
Proper	(604)
Federal contract research centers	(293)
Total	897
Other nonprofit institutions	155
Total	[1] 1,836

[1] Excludes $29,400,000 to "foreign" performers and $9,000,000 to "other" performers (primarily individuals).

C–10. Has the Foundation completed or is it engaged in studies as to the absolute or relative amount of Federal support warranted for applied research to meet national needs?

No. The Foundation has neither completed nor is it engaged in studies which deal directly with the question of how much the Federal Government should spend, either in absolute terms or relative to other sources of support, on applied research to meet national needs. However, it should be clear that the Foundation conducts surveys

which provide the basic information on the sources and distribution of expenditures on applied research by the Nation as a whole, as well as by the Federal Government. Moreover, NSF internal staff studies have dealt with a variety of issues which have a direct bearing on the question of the absolute level and relative scale of Federal support of applied research. These studies have dealt with such problems as the bases for differentiating between basic and applied research activities; the relationships between the two; the social and institutional processes involved in their interactions; and research support in the field of engineering. The manpower studies conducted by the Foundation are, of course, also highly relevant to questions concerning the dimensions and character of the support of applied research by the Federal Government.

It may be observed that determining "the absolute or relative amount of Federal support warranted for applied research to meet national needs" is a problem which poses difficulties similar to those identified and discussed in the National Academy of Science report on "Basic Research and National Goals." In fact, the contributions by two members of the Academy's ad hoc panel deal with questions of applied science, and it seems clear that a determination of the "correct" level of support in applied science may be even more difficult than in basic science because the latter can, in considerable measure, be related to needs in graduate education.

C–11. How are research grants audited by NSF?

C–12. Could another agency of the Government, such as DOD or NASA, provide audit services for NSF at institutions where both have grants?

The audit of NSF research grants, which is not conducted on all Foundation grants but is limited to a sample of these, encompasses three phases, each of which is accomplished by the Foundation's auditors using a specific audit program which is modified as appropriate.

The first phase of the audit includes (1) a review of background information concerning the grants and grantee organizations, (2) a determination that the grants have been processed in accordance with prescribed administrative procedures, (3) a determination as to the funding that has been provided, and (4) a determination whether required financial reporting on each grant has been received from the grantees and whether the reports received are adequate.

The second phase of the audit of research grants involves an on-site review. At this time, an evaluation is made as to the adequacy of the grantee's accounting and administrative procedures insofar as they pertain to NSF grant activities, including, on a selective test basis, the examination of direct costs incurred for the grants. Also, the auditors determine whether there has been (1) consistency in the grantee's accounting distribution of charges between the direct and indirect cost categories and (2) compliance with conditions of the grants. For the academic institutions, the NSF auditors ascertain whether the institution's indirect cost rate(s), as determined by a cognizant audit agency, is in excess of the maximum rate allowed by the Foundation. In addition, for grantees other than academic institutions, the NSF auditors determine the indirect cost rates applicable to the grants.

The final phase of the audit entails a review of the audit findings with the grantee and the Foundation's program and administrative

personnel. This review is to resolve all problems of an audit nature, and to develop recommendations to management which are included in the audit reports.

We believe that an agency, such as DOD or NASA, could provide audit services for NSF with respect to the determination of an institution's *indirect* cost rate which would be applicable to NSF grants. The development of indirect cost rates is based upon established cost principles used throughout the Government, and familiarity with the Foundation's programs would be secondary. It is a matter of Foundation policy to accept the indirect cost determination of any other Federal agency without further review.

The audit of *direct* costs charged to grants poses an entirely different situation, and it is doubtful that another agency of the Government could provide audit services for NSF. To perform an effective audit of NSF grants, the auditors must be fully conversant with the Foundation's programs including background information on practices, procedures, philosophy, and requirements of the grants. Before an on-site audit, the auditors must review the background material with the program staff and grants administration personnel. Further, it is necessary upon completion of the on-site audit for the auditors to review the findings with the program offices and the grants administration personnel before the audit report is prepared.

In view of the above, NSF believes it would be difficult for such agencies as DOD or NASA to provide audit services with respect to the *direct* costs incurred for NSF grants. Given time, it might be possible for auditors employed by such agencies as DOD or NASA to become sufficiently familiar with NSF programs to provide adequate audit services, but there is little reason to think that this would result in overall efficiency in the auditing of NSF grants—and there probably would be a number of problems created under such a system.

D. Support of Research Facilities

D–1. Has the support of research facilities in eductional institutions by the Foundation resulted in artificial and unwanted movement of competent researchers from their original institution?

The increased emphasis on science and the rapid rate of increase in enrollment in institutions of higher education have created a demand for scientific faculty of high quality which overreaches the supply in many fields. This situation of high demand and low supply has resulted in an increasing mobility of competent university scientists.

Several factors contribute to this mobility, only one of which relates to facilities.

1. University salaries have been increasing significantly. But because these increases are not uniform among the various institutions and the differentials are substantial, certain schools are able to attract to their campuses experienced faculty from other institutions. This phenomenon is by no means a new one. What *is* new is the large number of "rising" institutions that can now compete with the older "top-salary" universities.

2. Research has become more complex, more interdisciplinary, and more expensive. Institutions with recognized scientific strength and administrative foresight are competing more favorably in attracting competent scientists.

3. Scientists generally agree that research is a necessary part of academic activity if a faculty member is to keep abreast of current developments in his field and do a creditable job of teaching. They continually work to attain or maintain teaching loads at a level which will permit a reasonable balance between formal instruction and research, which usually includes the training of graduate students. Institutions which have arrived at such a balance are better able to attract competent scientific faculty.

4. Facilities are also a significant part of an institution's capability for recruiting or retaining faculty. Other factors being equal, a competent scientist might well move to another institution which had markedly superior research facilities, especially major technical ones, such as particle accelerators and special biological facilities.

It can be concluded, therefore, that any funds awarded from Federal sources for research facilities may have an influence on the movement of competent scientists by affecting any or all of the points discussed. Not only will such financial assistance aid the recipient institution to acquire more and better research equipment and space, but university funds may be released for salaries, for incremental faculty (which may in turn spread teaching loads), and for other direct research costs.

Facilities grants made by the National Science Foundation are based on scientific merit and the indicated ability of the recipient institutions to retain or improve their achieved degree of scientific

excellence. Thus, improved and expanded facilities acquired with the assistance of NSF funds enable the recipient institutions both to retain their competent scientists and to augment their staffs. Limited movement of competent scientists as a result of NSF research facilities grants is not undesirable, particularly when it helps strengthen institutions on the way "up."

It is worthy of note that the Foundation's contribution to the total amount estimated to have been spent for additions to physical plant at colleges and universities in academic year 1963–64 is approximately 2.9 percent.[1] In view of this, it is clear that the Foundation in its support of facilities has not significantly affected staffing patterns at institutions of higher education.

D–2. How has the geographical distribution of NSF support for research facilities differed from that of the other Federal agencies over the last 15 years?

Foundation activities which provide support for research facilities have been in existence for a period of about 6 years. These activities consist principally of two programs: (*a*) The specialized facilities program of the Research Division, and (*b*) The graduate-level science facilities program of the Institutional Programs Division.

The most recent and best information available on the geographical distribution of these facilities funds is available in a recent Foundation report.[2] These data, which cover fiscal years 1961–64, have been reproduced and appear on the following pages.

R. & D. plant obligations at educational institutions, by geographic divisions and States, by selected agencies

FISCAL YEAR 1961

[1] Less than 1/10 of 1 percent. Percentages may not add to total because of rounding.

D-3. When the Foundation supplies educational institutions with large-scale equipment, does a decrease in the amount of time available for teaching by senior professors and graduate students result?

D-4. What effect has the transfer of ownership of facilities and equipment to the grantee from the Foundation had upon the subsequent geographical distribution of research grants?

D-5. Do you anticipate that the Office of Education, pursuant to authority of the Higher Education Facilities Act, will take over a large measure of support of science facilities that heretofore has been mainly an NSF responsibility?

Facilities and equipment acquired through Foundation grants fall into two categories. These are: (*a*) the research apparatus acquired as part of a research or equipment grant—ordinarily limited to items in the "few thousand dollars" range, though occasionally as high as $10,000 or $20,000; and (*b*) major items of equipment, running as high as several million dollars, and building construction or renovation. "Facilities" grants or contracts are used for both of these purposes.

No detailed study of the amount of teaching done by senior staff and graduate students before and after the receipt of large-scale equipment grants has been made. Continuous contact with research and teaching patterns indicates that there is not a significant reduction in teaching by senior staff and that graduate students, although they may be spending full time on research by the time they begin to work on such equipment, have quite commonly (earlier in their graduate student days) served as graduate student assistants for one or more years.

Large-scale equipment is provided at both on- and off-campus sites. When large-scale items of equipment, such as cyclotrons, reactors, and computers are available on campus, senior staff and graduate students are able to work "at home" rather than losing time in travel to other laboratories where such equipment is available. Research time on major equipment at home can be arranged to allow investigators to meet class schedules.

Certain large-scale equipment and facilities must be off campus for environmental reasons. Radio telescopes must be in areas free of local electromagnetic interference, optical telescopes must be in areas which afford good viewing conditions, field stations must be in or near the natural environment to be studied, and upper atmosphere and space studies must be conducted in cooperation with satellite and probe launch sites, observation or communication sites, and laboratories. Therefore, certain highly important major areas of research cannot be pursued without taking scientists off campus for varying periods of time.

Such major on- and off-campus research facilities do not, in themselves, reduce the time available for teaching. They enable scientific instruction—particularly at the graduate level—to keep abreast with current advances in the various disciplines and graduate students to participate in research as part of the educational experience. Any reduction in time spent in formal instruction is offset by student experience and the quality of the formal lectures given. Upper division undergraduate and graduate students, in particular, receive significantly more valuable training through the availability of the most advanced equipment and the direct association with senior scientists working in forefront areas. At the graduate level, research and grad-

uate training should be intertwined. The availability of large-scale equipment lends itself to this process.

Apparatus of many kinds (but generally not such as might be called large-scale equipment) is often provided as part of an individual project research grant awarded on the basis of the research competence of existing faculty. Such equipment usually will not affect the institution's future ability to acquire significant increased research support. If an investigator, using such equipment under NSF research grant sponsorship, changes his organizational affiliation but continues his research activities in the same scientific area with NSF support, it is not uncommon for such equipment to be transferred to the new institution for support of that investigator; thus, even though title to the equipment is vested in the institution, the equipment is in support of the individual's research.

Where significant amounts of research space and large items of research equipment, such as computers or reactors, are acquired, the recipient institution may thereby improve to some degree its competitive position as it seeks further research support. The purpose in granting funds for buildings and major research equipment is to enable the institution to increase or upgrade its research and research training activities. These awards are made on the basis of existing or potential scientific merit and it is expected that the resulting expansion of research programs or increases in faculty will make it easier for the institution to obtain the required supporting funds. Therefore, those geographic areas most competitive for research facilities and equipment by virtue of their need and potential for upgrading will compete most favorably for a corresponding share of Federal research dollars.

Judging from recent enactments of authority and appropriations, the Office of Education probably will hereafter provide an increasing fraction of the support of classroom and laboratory buildings, and the National Science Foundation probably will, in turn, tailor its science facilities support to those areas where the Office of Education cannot provide adequate coverage, where special or urgent needs manifest themselves, or where novel or highly specialized facilities—e.g., research laboratories and major specific items of research equipment—must be developed. The Foundation's area of emphasis in these programs will continue to be at the graduate level. The facilities programs of the Office of Education and NSF, therefore, are complementary. The primary responsibility for meeting the large need for general facilities falls on the Office of Education, and the important responsibility for meeting urgent and specialized requirements (such as accelerators, biotrons, or reactors) and for innovation falls on NSF.

Section 2 of the Higher Education Facilities Act of 1963 states that a primary purpose of the legislation is to make certain that "the Nation's colleges and universities are encouraged and assisted in their efforts to accommodate rapidly growing numbers of youth * * *." Two titles of this act provide for grants for academic facilities. Under Title I, public and private nonprofit institutions of higher education in each State submit projects for the construction of undergraduate academic facilities to a designated State commission. Priorities are assigned to eligible projects and appropriate recommendations are made to the Commissioner of Education. Under title II,

institutions of higher education submit proposals for graduate academic facilities support directly to the Office of Education. An Advisory Committee on Graduate Education advises the Commissioner in the selection of grantees. The purpose of title II is "to increase the supply of highly qualified personnel critically needed by the community, industry, government, research, and teaching * * *."[1]

While the funds available for the support of graduate facilities through the Office of Education (under title II) exceed those funds available through the National Science Foundation, it is important to note that the authority of the Office of Education covers the support of construction of classroom and laboratory buildings (and ancillary equipment) in many fields of learning—plus libraries. Thus, in trying to provide adequate facilities to meet the needs of an expanding student enrollment, the Office of Education will face increasing demands for many kinds of graduate-level facilities—primarily the construction of buildings—across the entire spectrum of educational activity.

Thus far, out of 85 awards under title II, 51 (60 percent) were grants for nonscience graduate facilities.[2] The Office of Education has become a vitally important source of funds which can assist in meeting these important needs. As we understand their mandate and their plans, it appears highly unlikely that OE will wish to or be able to provide funds for major scientific research facilities, such as oceanographic research ships, particle accelerators, biotrons, or the like, for some time to come, if ever.

The Foundation, on the other hand, is concerned primarily with scientific excellence and scientific growth. For this reason we have stressed the importance of providing adequate, modern laboratory space where such facilities are required, either to maintain excellence in research and education or to encourage growth. As the Nation continues to invest in basic science, it is important to make certain that a lack of adequate science facilities does not impede our progress in science. Furthermore, there are certain types of research facilities for which support cannot be obtained through the title II program of OE, such as space for postdoctoral research fellows and for individual faculty members who may not be involved in graduate training. The Foundation provides support for these special needs. Thus, the Foundation, because of its responsibilities toward the progress of science, is often uniquely positioned to advance that progress by responding perceptively to requests for facilities.

Because there are basic differences between the objectives of the facilities programs of the Office of Education and the Foundation, these programs should be viewed as largely complementary to each other.

In 1962 a study conducted by the Foundation indicated that, for the decade 1963–72, the requirements for science facilities at colleges and universities would amount to $7.5 billion. On the basis of our present knowledge we believe that the needs for academic facilities in the years ahead will become even more evident than at present, and that these needs will best be met by the concerted efforts of several Federal agencies.

---

[1] The Higher Education Facilities Act of 1963, Public Law 88–204, sec. 201.

[2] Estimate based on "Notification to Members of Congress Regarding Public Law 88–204, the Higher Education Facilities Act of 1963"; HEFA Reports Nos. 60 and 110.

D–6. With respect to the national research centers, you testified as follows:

> *They must continue to be supported and their programs should be strengthened and expanded. Perhaps from time to time there may be occasion to establish more of them in special fields.*

Is the Federal Government funding the entire cost of the national research centers? Do participating universities contribute any part? Can you provide information on funding of research centers in general, and also on relative costs of supporting research at centers vis-a-vis project research?

The Federal Government is funding, for all practical purposes, the entire cost of the national research centers. Each of the centers is managed by a private nonprofit corporation established by an appropriate group or universities. The corporations each have some private funds at their disposal, including a small pool established through initial contributions of a few thousand dollars each by the participating institutions. In a few instances, the corporations have used their own funds for special needs of the centers which could not be met by Federal funds.

The funds for each center are identified in the Foundation's budget request as a special item separate from the general support of university research and research facilities. The management procedures used by the Foundation are much the same as those used by the Atomic Energy Commission for its national laboratories. The centers are Government-owned, contractor-operated laboratories, in which the management corporation is given broad responsibility and wide latitude to take the initiative in achieving the scientific objective laid down in the contract.

All of the centers established by NSF emphasize cooperation with university scientists. In the case of the observatories, a major objective is to provide observing facilities for outside users. Since these facilities are available at no cost, the effect is to reduce the cost of individual project research by university users. Hence, it is difficult to compare costs of research by the observatory staff with cost by university users without a rather elaborate cost analysis. In the case of the National Center for Atmospheric Research, participation by university scientists in laboratory and field programs is a major goal, in addition to the provision of specialized facilities. The real cost of research at a national center is probably about the same as the real cost at a university. However, contributions by the university, both explicitly identifiable and hidden, probably reduce the cost of research to the Government at a university below that of research at a fully supported center. It must be remembered, however, that our centers have been established to provide research opportunities which cannot be made available at universities, including large and expensive research facilities, and hence it is not strictly possible to make meaningful cost comparisons.

(See also D–7.)

D–7. What are the plans of the Foundation for national research centers to extend the concept to technical areas not presently included? What growth in the Foundation's budget do you foresee for continuing commitments for operations? To what extent is the Foundation involved in the operation and management of these centers?

The Foundation has no specific plans at this time to establish any new centers in technical areas not presently included. In general, it is

our policy to establish such centers only when it has been clearly demonstrated that setting up a new entity is the best (or only) mechanism we can discover for accomplishing the objectives sought. When a new center is proposed, for example, our first question is whether the same objective cannot be gained by strengthening programs in existing institutions.

It is estimated that the annual budgets of the present centers will reach approximately $45 million in the next 10 years, which is $23 million more than the total fiscal year 1966 allocation.

The figure given does not include a telescope for the Kitt Peak National Observatory larger than the presently authorized 150-inch reflector, although such an "x inch" telescope is now under discussion. The estimate does, however, assume construction of an equivalent 150-inch instrument at the Cerro Tololo International Observatory. At the National Radio Astronomy Observatory, a very large array is included, but no provision has been made for construction of a very large steerable paraboloid. The National Center for Atmospheric Research estimate does not include possible applied research and development programs, which might be supported by other agencies. It can be said in general that the need for new major facilities cannot be foreseen and will depend on how these scientific fields advance.

The Foundation contracts for management of the centers with three nonprofit corporations, which are given wide latitude in achieving the broad objectives laid down. Foundation involvement in management includes normal contract administration guided by Federal procurement regulations and continuous technical review by Foundation professional staff to insure that the scientific objectives agreed upon are being pursued vigorously and with emphasis on excellence. The Foundation is not directly involved in operation of the centers.

(See also D–6.)

D–8. Could you provide statistics on annual Federal obligations for research facilities in universities, apart from obligations for research and development facilities combined? What are the projected needs?

The Foundation does not have data from Federal agencies on their annual obligations to universities for facilities that are used exclusively for research. So far as is known, such data are not available from a single source, but would have to be collected from the Federal agencies.

However, the following data are available from agencies on their obligations for combined research and development facilities located on sites of educational institutions. These data exclude obligations for R. & D. plant to Federal contract research centers located on sites of education institutions, and thus represent only Federal obligations for facilities at educational institutions proper.

[In millions]

	Fiscal year 1964	Fiscal year 1965 (estimated)	Fiscal year 1966 (estimated)
Department of Health, Education, and Welfare	$38	$66	$68
National Science Foundation	40	53	58
Other agencies	20	26	21
Federal total	98	145	147

Source: "Federal Funds for Research, Development, and Other Scientific Activities," vol. XIV (not yet published).

It would appear, however, that almost all of these R. & D. plant obligations are for support of academic facilities used for research rather than for development. This assumption is based on the fact that during 1964–66, approximately 95 percent of obligations for research and development, excluding R. & D. plant, to universities proper was for research.

Similarly data are not available from Federal agencies on their projected obligations to universities for research facilities. However, a study made by the Foundation in 1961,[1] based on the relevant information then available, indicated that during 1961–70 a national investment from all sources, of about $2.8 billion would be required in laboratory buildings for basic research in colleges and universities. This estimate included the costs of new construction and fixed equipment.

A broader and more detailed study of college and university physical facility needs was made by the Foundation in 1962. This study indicated that the facility needs of universities and colleges for basic and applied research including graduate training in the sciences for the decade 1963–72 would amount to $7.5 billion:

	Billions
Building construction and fixed equipment (excluding land)	$4.3
Movable apparatus and furnishings to make building operable	2.5
Special and separate apparatus	0.7
Total	7.5

The educational institutions reported that 70 percent of their support was expected to come from presently identifiable sources. Those institutions that felt they could identify these sources of support with some degree of assurance estimated that on an aggregate basis almost 53 percent of the support would come from Federal funds, 34 percent from State appropriations, and the remainder from private sources. Public institutions that identified the probable sources of their support in detail stated that for every dollar of State support, $1 of Federal funds would be required. Private institutions, in contrast, stated that for every dollar of private support, $2 of Federal support would be required.

D–9. To what extent, if at all, does NSF review the engineering feasibility of construction plans for major facilities which it supports at national centers and at universities?

NSF reviews the feasibility of such facilities in terms of the scientific desirability of the concept, their general feasibility, and the general cost. For detailed engineering studies of the construction plans we rely on personnel at the centers or the universities, and their consultants and contractors, although we follow the development of such studies as they progress. For example: All of the architectural, engineering, and construction subcontracts related to the facilities being developed by and for the National Center for Atmospheric Research must be submitted to NSF before execution under the terms of the contract with UCAR.

[1] "Investing in Scientific Progress," 1961–70. NSF 61–27.

The facilities programs of NSF provide funds for specialized and graduate science facilities at colleges and universities. Program specifications, preliminary drawings, and, ultimately, actual working drawings are reviewed to insure that the university is constructing facilities as represented to the Foundation. An architectural unit within the Foundation has been established both to advise the universities and to insure that the Foundation's funds for facilities are well invested.

E. Science Education and Institutional Programs

E–1. In your view, which is more important to the National Science Foundation—the promotion of basic research or the advance of science education?

This question involves two separate but intimately connected considerations: first, which of the two, promotion of basic research or advance of science education, is more important to the Nation; and, second, what the role of the National Science Foundation is conceived to be in the overall effort to meet the Nation's needs.

From the point of view of national needs, it is difficult to see how the two can be separated. The promotion of basic research is fundamental, for it develops new knowledge and advances our understanding of the universe, as well as being the basis for new technological developments which will determine the nature of our economic and military position in the future, and will, perhaps as much as any other factor, determine our continued existence as a Nation. But none of the findings of basic research can be of any use at all without the existence of a corps of citizens capable of making use of that knowledge—capable of translating the fruits of basic research into useful tools, and the new knowledge into guiding principles.

Further, basic research is not an "interim" activity; it must be a continuing one, and for those now engaged in it there must be a continuing flow of replacements—replacements that can be trained only by a long process that ultimately involves, as part of the training, active participation in basic research.

Basic research therefore, in addition to being essential to the maintenance of the continued growth, if not the life, of the Nation, is an essential part of education. But basic research is not *all* of education. There is much of education that must precede that involvement in research that is a part of education—much of education that, especially in its early stages, must establish a broad base upon which can be built any of a variety of possible (foreseen and unforeseen) research specialties. The breadth of an individual's education will in general become narrower and narrower as his inclinations and talents dictate, but his education cannot be structured from the beginning toward a single specialized goal, if only because it is impossible to predict *now* where the frontiers of science will lie 15, or 10, or even 5 years from now. Wherever those frontiers are, the ability to pursue them is not developed overnight; it comes, except for the rare genius, only through a long period of education.

It is thus impossible to say that, to the Nation, one is more important than the other. Over the long haul, they are not separable. This does not say, however, that at one particular point in time we may not have to emphasize, temporarily, one over the other. One can imagine a situation in which it is obvious that basic research is going well, but it

is also obvious that basic research is going well, but it is also obvious that the education pipeline is very thinly populated, and something needs to be done to refill it. Or the education pipeline may be adequately filled, but support of basic research may have dropped to too low a level to provide the necessary opportunities for new research workers and the essential growth of new understanding. Either situation would demand a change in the pattern of support, and one of our pressing needs is for careful assessment of present and future requirements, and for flexibility in our support programs to correct imminent deviations from our determined course *before* they become critical.

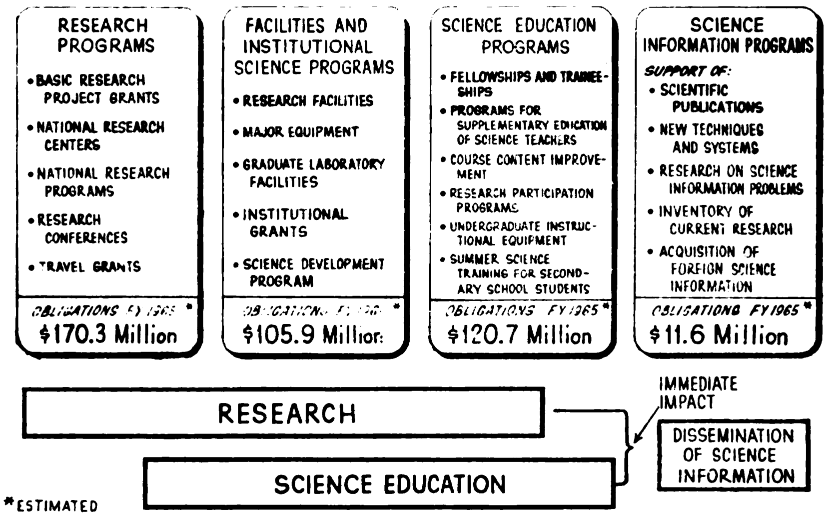
Which of the two is "more important" to the National Science Foundation, then, depends upon two factors: (1) which of them—basic research or science education—is *at a particular time*, most in need of temporary emphasis, and (2) what role the Foundation is expected to play in responding to newly apparent or changed needs. If the Foundation is expected to be a primary force in keeping both basic research and science education vital and productive, it needs not only current knowledge of, but a mechanism that will enable it (insofar as possible) to anticipate or predict the activities of other Federal agencies, and of the civilian economy as well. The very nature of research makes it impossible to arrive at dependable "long-range" predictions; the effort must be continuous, sustained, and uninterrupted. It needs, beyond this, the capacity to act quickly and decisively to meet new or anticipated problems.

Thus, in view of the inherently long-range nature of the National Science Foundation's fundamental task of promoting "the progress of science" on a broad base, it is literally impossible to make a clear-cut distinction between NSF support in research and in education. To promote basic research most effectively over an extended period of time, we must assure the health also of science education.

E–2. The testimony has shown that NSF support of universities is heavily weighted on the side of research, as distinguished from the education of students and the training of teachers. (a) Is this deliberate policy? (b) Do you see any danger of converting our colleges—that is, their science and research department—into great research laboratories?

In my oral presentation 2 months ago, I discussed with you a chart entitled "Mechanisms of Support" (presented again for convenience on the next page). In that chart, you will note that we show two bars labeled "Research" and "Science Education" underneath the boxes headed "Research Programs," "Facilities and Institutional Science Programs" and "Science Education Programs." These two bars were quite intentionally drawn in such a way as to overlap one another along much of their length—symbolizing the fact that in a large majority of our support it is virtually impossible to clearly differentiate between what is "research proper" and what is "education proper." A postdoctoral fellowship, though shown for fiscal and other purposes under the heading "Science Education" is in fact an award which usually involves research as well as education. Most of our research grants to universities are so heavily intertwined with the graduate education process that the two elements cannot be separated in any meaningful way.

NATIONAL SCIENCE FOUNDATION
MECHANISMS OF SUPPORT



Therefore, it seems to us very difficult to determine whether or not NSF support of colleges and universities is "heavily weighted on the side of research," because this quickly becomes a matter of judgment or opinion. There is no absolute measure or standard which can rationally be applied in trying to determine proper or optimum "weighting." As the chart I have mentioned demonstrates, we have no way of determining what fraction of our research support in the universities should be assigned to the research function and what fraction to the education function.

Because, at the graduate level, research is a necessary component of the educational process, its support, in any form is a contribution to education. Furthermore, a significant fraction of the research funds is applied directly to the support of students and their work. For example, we estimate that about $20 million of the Foundation's obligations for research in fiscal year 1965 provided salaries for research assistants who, for the most part, are graduate students; also, an unknown—but significant—portion of "research" expenditures supported the thesis research of this same group and of other graduate students who received their stipend support from sources such as teaching assistantships, fellowships, etc. Another $10 million (approximately) of our research support that year provided salaries for research associates—primarily postdoctorals; their participation in a research team certainly contributes to their advanced education.

An additional $105.9 million of NSF obligations during fiscal year 1965 provided support for the improvement of institutional science programs and facilities. Virtually all of these grants help strengthen the education capabilities of colleges and universities as well as their research potential. For example, grants under the science development program specifically provide for strengthening faculties, development of improved instructional programs, student participation in

research and other measures which enhance the quality of education in the recipient universities. Colleges and universities receiving institutional grants normally use the funds about equally for research and education. Better graduate laboratory facilities, another area of institutional support, directly increase the educational capabilities of universities. Another field of NSF support is the science information programs, for which fiscal year 1965 obligations amounted to about $11.6 million; activities which facilitate and accelerate the dissemination of the results of scientific studies are equally essential to the improvement of science education and the advancement of research.

All of these efforts are, of course, in addition to our direct "education" programs such as fellowships, traineeships, undergraduate scientific equipment program, institutes, course content improvement, etc.

In summary, therefore, one can say that the amount which NSF support contributes to the strengthening of education is roughly comparable to the amount it contributes to the conduct of research. The encouragement of graduate apprentice scientists under research support and the provision of institutional support to strengthen the science education capability are indeed "deliberate" efforts of the Foundation, but the "weighting" of one activity as against the other appears to be less important than to insure the adequacy of both.

It must be noted that to a major degree there is a basic difference between the sources of support for research and support for education. If external sources of support were not available, in many cases research at universities could not be done at all, and in other cases it could be pursued only at a much slower pace or in ways that would be less likely to yield significant results.

On the other hand the basic sources of funds for the educational activities of colleges and universities are non-Federal: tuition and fees, State and local governments, gifts, endowments, and investment income. These sources at least permit colleges to carry out what may be termed their "normal" teaching programs. The severe demands upon these funds, however, mean that it is very difficult and often impossible for colleges and universities to develop and introduce innovations designed to raise the *quality* of education available to students, to expand opportunities to enhance the capability of faculties, to contribute as only institutions of higher education can to innovation in precollege education. Hence, NSF support for education has been geared to raising the quality of education, to enabling institutions and the educational community as a whole to undertake tasks they could not otherwise attempt. The availability of support for education innovation has, indeed, helped to redress the imbalance of 10 to 15 years ago, when Federal funds were available mainly for research and graduate education. Witness to this is the involvement during fiscal year 1965 of thousands of scientists from colleges, universities, and research laboratories in creating new courses and instructional materials, conducting special programs for students and teachers from elementary school to graduate levels, and other educational programs. The search for ways to increase the commitment of leading scientists to education is a continuing concern of the Foundation.

The key problem, I believe, may be less the apportionment of funds between research and education than the total Federal aid available for both purposes.

Finally, it must be emphasized that there is a continuous interplay between research and education in other ways than in the training of advanced students. In addition to their obvious involvement at the graduate level, scientists from leading research departments have provided substantive leadership for major curricular innovation. This interplay is also reflected in many other projects supported by the Foundation, ranging from the "discovery" approach in elementary school science through research participation by high school and college students and teachers to the influence of ongoing research on classroom teaching and the effects of teaching on the identification of fruitful research possibilities.

At this time I see no danger of converting our college and university science departments into research laboratories. I do not believe Federal research support has damaged the educational capability of universities. Rather it has enhanced it, at all levels, especially at the graduate level.

E-3. Do you consider that the act of performing research is in itself a fundamental learning process, of practical educational value to students in college?

Definitely, yes. We are assuming here that the phrase "students in college" refers to undergraduates, since there is widespread agreement that graduate education is intimately and necessarily associated with research—and especially since the position of NSF with respect to the close coupling of research and graduate education is well known.

NSF initiated programs a number of years ago which emphasize the conviction that research participation is of practical educational value to undergraduates. Able college students who engage in independent inquiry as junior colleagues of experienced scientists develop more rapidly in scientific maturity and in scientific competence. They are thus better equipped for—and are more likely to undertake—graduate study than their peers who have not had such opportunities. The effects on college faculty members supervising these students and on undergraduate courses and curricular patterns in affected departments may be more difficult to isolate and identify, but there is no question that these effects do exist and are important as agents of evolution in producing increased effectiveness in undergraduate education in the sciences.

Those working actively on undergraduate curricular improvement, with or without NSF support, agree that one of the ultimate tests of the effectiveness of any academic regimen is the degree to which the student develops an ability to work confidently, effectively, and independently in new situations. There are ever-increasing numbers of efforts being made to engage students in investigative activities during both the college and precollege years so that skill in inquiry will develop along with increasing grasp of fact and concept.

In the period from 1959 through 1965 NSF has made 3,373 grants to colleges and universities to help them provide meaningful research participation (and comparable "special") opportunities for undergraduates. We are confident that the $30.5 million used for this activity has been an important and worthwhile national investment.

(See also E-12.)

E-5. What percentage of NSF's own funding goes to universities or individuals associated with them? Why does not NSF give greater support to nonprofit research groups? To private foundations?

It is estimated [1] that, in fiscal year 1965, 78 percent of the Foundation's total obligations of $409 million [2] for the direct support of science went to universities, colleges, and individuals associated with them.

A principal reason for concentrating basic research support in educational institutions is that these are traditionally the loci of a large proportion of the basic research of the Nation. Furthermore, basic research thrives best and provides important ancillary benefits when it is conducted in conjunction with educational activity, since each complements the other. No other type of potential grantee can offer so much in the way of possible long-range benefit to the country. Therefore, NSF has felt that it had, and has, a particularly important role to play in supporting academic research and educational programs based on the interest and competence of scientists and engineers in our colleges and universities. Increase of support to nonuniversity, nonprofit research groups could have a further deleterious effect of drawing additional scientists away from the institutions of higher education to such noneducational groups.

Nonetheless, NSF has considered with care (and has frequently supported) proposals submitted by nonprofit research groups and foundations engaged in research. Proposals from such groups are considered fully eligible for support and are evaluated in competition with all other proposals. If more such organizations submitted larger numbers of meritorious proposals to the Foundation, there would be more support of such research groups.

E–10. Have Government-wide standards been established for scientific fellowship awards and stipends? If so, who establishes them and what are the standards?

At the time the National Science Foundation inaugurated its first fellowship program, in 1952, it took the lead in convening an informal meeting with other Federal fellowship administrators to discuss provisions of the various fellowships then in existence. Additional meetings, usually chaired by the head of the Foundation's fellowships section, have continued to be held, at first once a year but more recently twice a year. By means of these conferences, a high degree of uniformity has been achieved in scientific fellowships supported by the Government in such areas as predoctoral stipends and cost-of-education allowances.

No Government-wide standards have been established, however. The minor variations that exist sometimes stem from differences in congressional authorizations. In the NDEA-title IV fellowships, for instance, the stipend has been set by Congress for an academic year of study at a figure slightly in excess of the predoctoral stipend in other Federal fellowship programs. Methods of selecting recipients also vary. To illustrate, section 10 of the NSF Act of 1950, as amended, specifies that the Foundation shall select individuals for fellowships solely on the basis of ability. The Foundation has interpreted this language to mean that individuals shall compete for the fellowships in a national competition. Our procedure for selection is that all applicants

[1] This estimate appears in the "Basic Charts and Tables" prepared in connection with the NSF hearings before the House Subcommittee on Science, Research, and Development.

[2] This figure excludes funds for studies of national resources for science and technology, and for program development and management.

are evaluated by panels of scientists assembled in Washington for that purpose, following which the Foundation selects individuals to receive fellowships on the basis of the panelists' recommendations. Other Federal agencies do not have such a legal requirement. For example, in the NDEA-title IV fellowship program, universities that have been allotted fellowships by the Office of Education select the students to be supported. The same is true of the Foundations' traineeship program.

(See also C-1; E-11.)

E-11. How does the Foundation coordinate its educational support with the National Institutes of Health, NASA, the Atomic Energy Commission, the Office of Education, and other Federal agencies that are concerned?

The bases of the Foundation's position regarding interagency coordination are: (1) Mission-oriented agencies must be enabled to engage in such education-support programs as are necessary to permit them to successfully perform their statutory functions; (2) in general, some overlap of effort is desirable because it tends to preclude an undue degree of standardization and control; and (3) coordination must be effected at all levels—from top level, policy-determining groups to program administrators. The most effective coordination seems to be that resulting from informal, day-to-day communication between operating staffs of the respective agencies. The effectiveness of this kind of coordination is dependent upon the desire of the staffs of the sister agencies to cooperate.

Coordinated planning and program management continues to be very effective with respect to the Office of Education, the Atomic Energy Commission and the National Institutes of Health. Because of the relatively smaller commonality of interests, there is less interchange on educational matters (but by no means zero) with DOD, NASA, and other agencies. With respect to the Office of Education, the agency with which coordination is of first importance, coordination is effected in a number of ways. Both agencies have executive-level membership on the Federal Interagency Committee on Education. The Commissioner of Education serves in person on the Foundation's Divisional Committees for Education, the advisory body which guides the development and administration of all of the Foundation's educational activity. Reciprocally, the Foundation's Associate Director (Education) serves on the OE Advisory Committee for the Higher Educational Facilities (title II) activity, an area of major interagency interest. The Foundation's Director of the Division of Precollege Education in Science serves on the OE Advisory Committee to the NDEA title VII program (new educational media) and in that capacity assists in the formulation of OE policy and selection of projects for support in an area of mutual interest. A key program officer of the Foundation's course content improvement activity serves on the OE Advisory Panel on the curriculum and instruction program, the OE program that includes the counterpart of the Foundation's course content improvement activity. Lastly, proposals received by one agency but which might be of interest to the other are exchanged. This sometimes leads to joint support, sometimes to mutually agreed unilateral support, and sometimes to agreement to provide no support.

Each year the Foundation formally utilizes the services of approximately a dozen of the OE staff as consultants to the Foundation to evaluate specific projects. Frequently, the Foundation provides this same kind of consultant services on an informal basis to OE. Lastly, OE has sought advice and suggestions extensively from the Foundation's staff on effective ways of administering various aspects of the new and large program authorized by the recently enacted Elementary and Secondary Education Act of 1965.

The overall result of this varied group of coordinating mechanisms is a set of programs which reinforce rather than compete with each other. Furthermore, we have been able to reach decisions, permitted by the respective statutes, that one agency will refrain from engaging in certain activities that are currently handled effectively by the other.

Community of interest with other agencies in science education is substantially less, and there are therefore fewer coordinating mechanisms. The institutes for teachers in radiation physics and in biology, which are of joint interest to NSF and AEC, are administered jointly by the two agencies. Those projects mutually agreed as supportable are jointly supported: NSF provides for participant costs and the AEC funds the operating costs. Fellowship activities are coordinated through a Government-wide (informal) interagency fellowship coordination group which meets approximately twice each year. In summary, interagency coordination on educational support activities is a matter of continuing concern, and one which has thus far proven manageable and effective.

(See also E–10.)

E–12. At what grade level, in our modern educational structure, does a student chart his course toward science, engineering, social studies, or the arts? Should NSF exert influence by the investment of support at this level? Should your fellowship or institutional support of pregraduate education be proportionately increased or decreased?

In our educational structure the student usually commits himself to a subject matter major during his sophomore year in college. While designation of such a major in science is essential to a career in science and is more often than not followed by such a career, the factors leading to this designation have their origins many years earlier.

According to developmental studies, interest in science and mathematics seems to arise early, even in elementary school. Certainly by the junior high school years, or ages 12 to 14, a significant proportion of boys and girls who ultimately follow careers in science have declared interest in these fields. While there is some additional gaining of "recruits" to science and mathematics through the high school years, in the main there is a decrease in the total numbers because of a falling off from the peak numbers of the junior high school years during grades 10 through 12. Students make decisions which tend to remove them permanently from potential scientific careers by failing to take a full 4- or 5-year program in mathematics in high school, or neglecting to take one of the physical sciences, usually physics. Thus the group remaining in the pool of potential scientists by the time they reach college can be identified by their choice of high school courses. (Of course, large numbers of those with a complete high school program in science and mathematics will not choose to major in these areas

either, but it is very difficult for a student who does not have these prerequisites on reaching college to make up for the lost time if he wants to major in science.)

Thus, it would seem that the important period for the charting of a student's career in a scientific profession lies in the senior high school years. At these grade levels, exposure to new course content materials and participation in activities which extend beyond the usual classroom hours can be highly effective in revealing the attractions of the sciences and can help to cultivate work habits and thought processes necessary for subsequent achievement in these fields.

A particularly effective way of conveying to able secondary school students the essence of what a scientific career is like is to expose them to mature scientists who have an interest in dealing with this caliber of student. NSF has found that an excellent device is the summer program devoted to course work and research participation in laboratories, taught by experienced scientists in an atmosphere of high level performance. Other methods of bringing the student into closer contact with the scientist include arranging for visits of scientists to schools on special occasions, and participation of especially able students in special seminars or meetings held during the academic year.

No one questions the prediction that effective work in science and technology in the decades ahead will require more individuals trained at the graduate level; thus, consideration must continuously be given to the pool from which graduate students will be drawn. There must be a sufficiently large group entering college and predisposed toward science to allow for attrition during the undergraduate years and to permit a reasonable selection ratio for graduate education. In terms of a pyramid, encouragement by NSF of the potential scientist while he is still in high school will enlarge the base in support of the narrow apex represented by the research scientist.

While it is not assumed that it is possible or advisable to divert very large proportions of superior students into the scientific fields, an increase in support of precollege programs would add significantly to the proportions of students studying science in college. For the moment, we do not see any need to alter substantially the relative support of programs of this nature, but they should be provided support at an increased level as other activities grow.

(See also E–3.)

E–13. To what degree do graduate engineers and scientists drift away from their professional vocations into other fields—such as management, trade or commerce, finance or other business? Is this good or bad? (E.g., less than half of chemistry majors remain in the field.) What can be done to improve career counseling?

Whether a student who obtains a bachelor's degree in science or engineering enters employment in his "major" field depends on a complex of factors which vary according to discipline. During certain periods engineers with bachelor's degrees have been widely sought after and an overwhelming percentage are employed in that field within a short time after graduation. Chemists, on the other hand, do not necessarily find that their bachelor's degree qualifies them for rewarding work in the field, or even for routine jobs, depending on the market. A study [1]

[1] "Two Years After the College Degree," National Science Foundation (1963).

of 1958 bachelor's degree recipients (male) 2 years after obtaining their degrees showed the following: Engineers—about 85 percent in engineering jobs; chemists—about 35 percent so employed; mathematicians—less than 20 percent in professional mathematical work (excluding secondary school teaching). These figures reflect, in part, the varying need for advanced degrees before the young college graduate can be considered a full-fledged member of his profession. The figures on secondary school teaching are also of some interest: Only about 10 percent of the engineers and chemists, but nearly 37 percent of the mathematics majors had become secondary school teachers within 2 years after graduation. Listed as college teachers are 2 percent of the engineers, 10 percent of the chemists, and 7 percent of the mathematicians.

Not unexpectedly, enrollments for graduate degrees during the 2-year period between graduation in 1958 and the spring of 1960 show something of an inverse relationship to employment in the field for these bachelor's degree holders—about 22 percent of the engineers, 51 percent of the chemists, and 38 percent of the mathematicians were engaged in graduate study. There is a strong tendency for the field of graduate study to be the same as the undergraduate major, although there is some drifting into related scientific fields.

The designation of an undergraduate major is often somewhat arbitrary, involving a minimum of credits and often supported by a strong minor in a related area of study. Depending on the employment market, the new bachelor's degree recipient may find himself unsuited for work in his major field because of a mediocre academic record, or because of the need for graduate education, or for other reasons. Such factors as these result in some science "dropouts," and some shifting of areas of specialization within the scientific disciplines, whether with respect to the kind of job accepted or field of graduate study undertaken. By and large, I think that these "corrections" within our educational structure are of significant benefit to—and indeed represent an important "freedom" of—our society, and that they permit a fuller development of each individual's interests and his capacity to contribute to the Nation's overall potential.

With increasing years after graduation the tendency to leave the specific field of college major increases. Often this is due to increased scope of job opportunities which leave the specifically technical responsibilities behind. Often a promotion from a technical job to a managerial post keeps the engineer or scientist within the same organization, and his technical or scientific background is still a requirement—though less obviously so—for the administrative decisions he must make. A factor of importance in shifting of careers from the technical to the more general or administrative is the obsolescence of knowledge and skills. This is an especially serious matter in engineering where the rapid advance of technology nowadays overtakes the engineer 5 or 10 years out of school. Refresher training has become a critical issue in this field, just as continued scholarship and advanced training have always been considered vital for creative scientists.

Receipt of the doctorate, in general, results in a strong commitment to the field in which the degree is earned. Of those who had obtained the degree by 1960, 92 percent of the engineers, 90 percent of the

chemists, and 84 percent of the biologists were working in the fields represented by their degrees.[2]

Career counseling can be just as useful in helping keep out of the pipeline those students who have low aptitude for or low interest in science as it can in encouraging the able and interested student to undertake a scientific career. The key issue is the basic competence of the counselor more than better techniques of counseling. Further strengthening of training programs for counselors, particularly with regard to increasing their understanding of matters related to the scientific and technical professions, would be very helpful for high school and college counseling staffs. Also important, however, is an early introduction of the student to realistic situations in the discipline of his choice—provision for experiences such as extended contact with working scientists, participation in research, and involvement in directed "advanced" study—both before attending college and during his undergraduate years, so that he can make a more adequate judgment as to his ability to fit into such careers.

(See also H–7.)

E–14. In supporting science education over the humanities or one field of science more than another, does the Federal Government incur an implied obligation to provide employment in the future for those graduates it has supported? Do students incur any implied obligation to stay in the field or to work on federally funded programs?

Recipients of NSF fellowships and traineeships are explicitly advised that acceptance of these awards does not obligate them, the Foundation, or the U.S. Government in any way with regard to future employment or future services of any kind. Nor is there any implied obligation of future employment in other Foundation-supported activities. However, in certain programs specifically designed to enhance the competence of individuals to do the job to which they are already committed—e.g., teaching of science—preference is shown (properly, we feel) to those who indicate their intention to resume their regular kinds of employment at the completion of their NSF-supported training activity.

Some other Federal agencies that support educational programs also employ relatively large numbers of scientists and engineers. They believe that their contribution to increasing the supply of trained scientific manpower will assist them in recruiting the highly qualified personnel they will need in the future by adding to the pool of trained manpower in their fields of interest.

It is estimated that more than half of all R. & D. scientists in the United States are working for or on behalf of the Federal Government. We can thus be sure that a significant proportion of those persons receiving training with Federal assistance will eventually be involved in work of direct importance to the Government. Those who enter jobs which are not directly associated with Federal missions nonetheless contribute in a variety of ways to the advancement of knowledge, to the education of our youth, and to the production of goods and services important to the health of our economy.

---

[2] This information was obtained from data acquired in the postcensal survey of professional and technical manpower.

E-15. Could you provide results of any studies of the short- and long-range national needs for support of basic science and science education, and how are these needs reflected in any long-range plans of the Federal Government and of the NSF itself?

I take it for granted that a number of published studies dealing with "the short- and long-range national needs for support of basic science and science education" are already available to the committee. What I have in mind here are not only the various studies and surveys conducted by the Foundation on the Nation's current and future resources for science, which are relevant to the problem of determining national needs over the shorter and longer run, but also a body of published materials for which the Foundation has no direct responsibility even though it may have provided staff or other assistance in their preparation. Among these are reports by the President's Science Advisory Committee; by the study panels which operate under the auspices of the Committee on Science and Public Policy of the National Academy of Sciences and by the Committee itself; and by ad hoc study groups or committees created by different agencies. In addition, there are still other examples of published reports in the development of which the committee has played a key role. Its contract with the National Academy of Sciences has resulted in "Basic Research and National Goals." By arrangement with NSF it has made provision for the publication of a series of reports on science education, the first of which, "Science Education in the Schools of the United States," appeared in March of this year.

It is not difficult to show that the results of a handful of studies of "national needs" have been reflected in the longer range planning activities and decisions of the Foundation and of the Federal agencies concerned with basic research and education in the sciences, and even of the Federal Government as a whole. I could cite, by way of illustration, the influences—in some cases extremely far reaching—exerted in this regard by such studies and reports as "Science: the Endless Frontier"; PSAC's "Education for the Age of Science" (1959); "Scientific Progress, the Universities, and the Federal Government" (1960); "Meeting Manpower Needs in Science and Technology" (1962); and "NSF's Government-University Relationships in Federally Sponsored Scientific Research and Development."

A recommendation made in the last, for example, laid the basis for Public Law 85-934 (1958) which permits all science-supporting agencies to employ the grant device as well as contracts. PSAC's 1960 report on "Scientific Progress, the Universities, and the Federal Government" played a role in connection with the development of NSF's institutional grant program and its science development program. The observations made in PSAC's 1959 report on "Education for the Age of Science" have been reflected in the enlargement of NSF's efforts in the areas of course content improvement and curricular reform. In the expansion of Federal programs for the support of graduate students in the sciences and engineering since 1963, a definite role may be attributed to PSAC's report, "Meeting Manpower Needs in Science and Technology," of the preceding year. The PSAC-inspired "Towards Better Utilization of Scientific and Engineering Talent—A Program for Action" (1964) has given us food for thought for some time to come.

I would do less than justice to the importance and difficulty of this question, however, if I stopped at this point in my reply. It is important to recognize that all studies dealing with problems of short- and long-run "national needs," whether prepared for internal use or for general publication receive serious and searching consideration by the various Federal agencies and by the Congress. They are grist for the mill of continuing policy and program review and planning activities deeply embedded in governmental processes which have to take future "national needs" into account. For this reason, however, it is frequently extremely difficult, without undertaking intensive investigation, to identify the influences exerted by any specific study of the kinds to which the committee refers and to show their reflections in the long-range planning of an individual agency or the Government as a whole. Some studies, moreover, may exert their major influences indirectly and over long periods of time. I would be surprised if this did not turn out to be the case with "Basic Research and National Goals."

The nature of the question encourages me to make two other observations. The first is that long-range planning activities with respect to the support of basic research and education in the sciences represent a fairly recent concern in the Foundation and other agencies of the Federal Government. The methods for comprehensive long-range planning in relation to short- and long-range national needs are still at an early stage of development. Undoubtedly, they can be vastly improved, but no one should minimize the inherent difficulties associated with attempts to assess the character of "national needs" for a highly uncertain future.

The second observation is that the main point of the question may, perhaps, be stated as follows: "Will current U.S. and NSF policies in the support of basic research and education in the sciences, if they are permitted to stand unchanged, meet the national needs in the long-range future?" Put in this form, the question virtually compels one to recognize a major lack in the studies concerning long-range national needs. Those which have been undertaken tend to focus on the interests and resources of either separate disciplines or individual agencies, rather than on those of the Nation at large. In all honesty, it must be admitted that thus far there have been no broad, systematic, and intensive studies designed to develop an understanding of alternative policy structures and options open to the Nation as a whole and to assess the associated opportunities and risks, as well as the impact, which such policies and choices might have on individual agencies, disciplines, and the Nation's goals. NSF has recently begun a series of exploratory activities designed to help develop such understanding. The PSAC "summer study" currently in progress is exploring the long-range needs for academic research support.[1]

There is a growing—worldwide—concern with respect to these matters. Scholars in a number of countries have begun to investigate, in a systematic way, economic and other aspects of these problems. I cannot with confidence predict the quick resolution of the many policy issues that are involved in this domain, but I am reasonably sure that within the next year it will be possible to list a number of new and promising developments which no one could have foreseen 5 years ago.

[1] See also our response to question B–7.

E-16. In your testimony you noted that the Foundation's science development program was established to boost near-excellent institutions to first-rate status and in the future to assist promising departmental "islands of strength." (a) What criteria are being employed for awards in either case? (b) What are the total national needs and what are the fiscal implications for the Foundation?

(*a*) The Foundation's science development program was announced in March 1964 with the major objective of increasing the number of institutions of recognized excellence in research and education in the sciences.

The criteria used in making science development grant selections are necessarily rather broad since proposals vary widely. As examples, the following broad criteria are considered in evaluating each proposal:

1. Administration and management:

(*a*) Evidence of interest and support from all sources, e.g., alumni, trustees, State legislature, Federal agencies, and community.

(*b*) Presence of effective administrative leaders (president, vice presidents, etc.).

(*c*) Strength of scientific leadership (deans, department heads, faculty, etc.).

(*d*) Effectiveness of the organization proposed for carrying out the science development plan.

2. The present situation:

(*a*) Existing strength in science to serve as a base for the proposed development.

(*b*) Evidence that significant improvement is underway throughout the institution's science activities.

(*c*) Collateral strength, including strength in the humanities, which will contribute to the success of the plan.

3. The science development plan:

(*a*) Relationship of the proposed plan to the institution's overall development plan (extended forward at least 5 years).

(*b*) Evidence that personnel requirements have been realistically appraised.

(*c*) Likelihood that the level of quality achieved and the level of funding required can be maintained after NSF support from this program has terminated.

(*d*) Commitment of institutional resources for both the immediate and distant future.

(*e*) Possible favorable impact on nearby institutions (through collaborative programs).

(*f*) Possible adverse effect upon other institutions.

The above criteria are used in the present science development program, where the emphasis is on helping the institution as a whole take a major step forward in its scientific strength. We hope soon to initiate a new program of smaller grants in which the institution will present a plan for significant improvement in its work in a selected scientific field where it has some potential for excellence. This program will not expect to bring about a significant change in the institution as a whole. Criteria for the program will focus more on the available faculty and plans for strengthening the particular field. We

will, of course, require evidence that the institution is ready and able to back the proposed move. In all cases, there will have to be an existing "pocket of strength," and in no event will we simply give the administration a "hunting license" to recruit an entirely new group.

(*b*) There are no good estimates concerning the total national needs. The main objective of the present science development program is to increase the number of institutions with top quality science programs. Also, it is recognized that a 3-year grant of $3 to $5 million can serve mainly as a major boost. Even with this limitation, it may be noted that by the end of fiscal year 1965, 68 institutions had submitted science development proposals requesting a total of $275 million. To date, the Foundation has announced grants totaling $35,679,000 to 10 institutions. The budget for the science development program for fiscal year 1965 was $28 million and for fiscal year 1966 is $40 million. A few million dollars of the latter will be devoted to the program for developing departmental "islands of strength." It is estimated that 40 to 50 additional proposals, amounting to $160 to $200 million, will be received in fiscal year 1966. It is clear that the present budget structure permits only a small fraction of institutions to receive a major science development grant.

The experience of the Foundation during the first year suggests that additional and different institutional development programs are needed for different reasons. For example, many less visible institutions have immediate needs and potential for relatively great upgrading in the quality of their science programs. Also, most liberal arts colleges appear not to be well-suited to compete in the present program.

While it is now clear that the Foundation's science development program, as presently constituted, cannot meet the variety of needs present in the undergraduate, small, liberal arts colleges and even in some of the developing universities, staff work is proceeding in an attempt to determine how NSF can best approach a problem of such magnitude.

E–17. What contribution have the small college and the young unknown investigator to make toward the betterment of science? What specific effort does NSF make to assist them and take advantage of their potential?

The contribution of the small college to the betterment of science may be measured in many ways. In a quantitative sense, if one divides the approximately 1,130 institutions offering science instruction at the baccalaureate level into those that produce more than 150 baccalaureates in science per year and those that produce 1 to 150, about 942 colleges appear in the second group. Approximately 33 percent of the annual national supply of new science baccalaureates graduate from these smaller schools, and thus two-thirds of each year's group of graduates emerge from the 200 or so larger institutions.

In terms of quality the small colleges range from superb to very weak; their students also represent a wide range in terms of ability. As a consequence, the graduates of the small colleges have emerged at all levels of eminence in our society.

The Foundation's efforts to improve the quality of undergraduate instruction include components of faculty development, support of curricular improvement through such groups as college commissions and writing groups, implementation of course and curricular modifica-

tions through the equipment program, and support for the participation of able undergraduates in research. The Foundation also supports a variety of special projects such as the formation of inter-institutional associations designed to identify and encourage able young scientists who are trying to carry on both instructional and research activities in the small colleges.

The relative magnitude of NSF efforts in this area is small when compared with the total need. However, the Foundation has devised and tested a variety of approaches to the improvement of quality of science education in the colleges and these approaches are available to serve as models for more massive assaults on major problem areas.

As for the young investigator, the Foundation recognizes that all established scientists were once young and unknown. Means now exist for helping the able student of science to complete his training—but more needs to be done to make sure that he can gain support for his first independent research.

A significant effort by the Foundation in this direction is its program of research initiation grants in engineering. These grants are restricted to younger faculty members who received their doctoral degrees within the past 3 years and who have not received substantial research support since starting their teaching careers. During the past fiscal year 126 grants were awarded to 71 institutions (65 percent of those applying) in 36 States. The Foundation's interest in increasing the potential of young faculty members in the smaller institutions is pointed up by the distribution of the grants. Only 14 percent were awarded to the 12 major schools which collectively award 50 percent of the doctoral degrees in engineering; the vast majority (86 percent) were awarded to the smaller engineering schools. For the past 2 years more than $1.5 million of the Foundation's engineering research funds have been reserved for this program. An even larger amount is planned for fiscal year 1966.

(See also E–20.)

E–18. On the subject of faculty training, you testified as follows:

> ***Research funds should be made available to promising younger members of science and engineering faculties who have not yet achieved reputations and whose chances of securing Federal research support are understandably small, given the accepted and desirable criteria of proven merit and high quality.***

If NSF supports meritorious proposals and makes its judgments on this basis, it is really considering a double standard to support also "meritorious" people. What relative weights should go to the person and what to the project?

In evaluating proposals from an established, older investigator it is felt that substantial weight should be given to his research performance in the recent past, since he usually will have produced a number of papers which have been widely read and judged by many of his colleagues. The research proposal under immediate consideration needs to be given relatively less (though still careful) consideration unless it happens to require the purchase of new and expensive equipment or services.

In the case of a younger person more weight must be placed on the evaluation of his proposed project since information derived from an analysis of his past work is much more limited. Were it not essential to encourage younger men, and for the fact that the most

original ideas are frequently produced by them, limited support funds would almost always be channeled to older, proven investigators.

E–19. Does the Foundation concur with the targets for master's degrees and Ph. D.'s established by the Gilliland Panel? Are these targets being met? If not, what steps are necessary to increase production, particularly of engineers?

The Foundation agrees with the import of the report [1] of the President's Science Advisory Committee (the "Gilliland report"), issued December 12, 1962, to the effect that an adequate supply of well-trained physical scientists, engineers, and mathematicians is essential to the orderly progress of this Nation. The Foundation also believes that the problems inherent in the area of scientific manpower are continuing ones and require periodic examination, reassessment, and actions. The problems involve a complex interplay between the nature and scale of our training of persons to various levels of competence and the way in which scientifically or technically trained persons are utilized. The latter necessarily must include consideration of the needs of both the public sector and the private sector. Our total manpower resource should at all times be adequate to support large-scale, national, scientifically related programs (e.g., defense technology, supersonic transport development, the space program). But we must also keep our economy healthy and growing—and this too demands trained scientists and engineers. Obviously we want to make sure if we can that we have available at a given time the manpower necessary to do the job then to be done. And there is a distinct difference between what has to be done and that which would be desirable to do, although the distinction is hard to make in practice. The most acute shortage has been, and almost by definition will continue to be, at the highest levels of competence. Measuring competency levels of those trained in terms of level of degrees granted is not uncommon and has certain practical advantages. It is not of course wholly valid. Especially when viewed in terms of what engineers do and what they will be called upon to do in the future, and relating these to what engineering students are taught (there are great disparities in curriculums and objectives from school to school) absolute numbers, either as to future supply or demand, should be viewed as valid only within wide limits of error.

These points of view lead, in turn, to viewing the manpower production goals of the Panel (7,500 Ph. D.'s and 30,000 completing at least 1 year of graduate study in EMP fields in 1970) as being not unreasonable—but also not firmly fixed. The Foundation would consider these goals to be a reasonable approximation of the needs as seen at a given point of time. The Panel did not claim that its target figures were the "right" ones—but rather that they represented goals that could be reached and that should be viewed as being worthy of additional Federal investment to achieve. NSF has been and is in agreement with this view. It is important to remember that many important and relevant matters were left essentially untouched in the report under discussion, for it was (as its title notes) the first of a series. Among the problems not dealt with were: graduate training needs in the social sciences and the life sciences; postdoctoral training in general; and the ways in which teaching and research assistant-

[1] "Meeting Manpower Needs in Science and Technology." Report No. 1: "Graduate Training in Engineering, Mathematics, and Physical Science."

ships could best be made use of in moving toward a greater production of advanced degrees.

Graduate degrees awarded in the physical sciences, mathematics, and engineering reflect the increased emphasis placed upon these fields, and have increased through the academic year 1963–64, the last for which data are available. Projections prepared by the Office of Education and by the National Science Foundation agree that the goals proposed for 1970 by the Gilliland Panel are attainable, providing these trends continue.

It must be emphasized, however, that the continuation of the trends and the attainment of these goals depend upon the further commitment of resources of faculty, facilities, and student support. We are in a position where the proposed goals are now possible of attainment thanks to the hitherto unprecedented support provided for these fields in the late 1950's and early 1960's. However, further increases of about 60 percent in the doctoral and master's degrees awarded in 1970 over 1964, which will be necessary to meet the Panel's goals, will require both the continuation of past efforts and a substantial further effort on the part of all parties concerned.

E–20. Since research and science education are so intimately linked throughout the NSF authority and program, what does this portend for the small college which is unable to support a vigorous R. & D. effort but still wishes to graduate high quality bachelors of science?

The linkage between instruction and research activity becomes progressively greater at progressively higher levels of education. At the graduate level, for example, they are virtually synonymous.

At the undergraduate level some research type activity, for both teachers and students, is important. It should be borne in mind, however, that the relevance of research to undergraduate instruction is to be found more in its instructional import than in the significance of its results in terms of new knowledge. It follows then that the criteria for support of *research activity* relevant to undergraduate instruction should be different from those relevant to the discovery of new knowledge. Many small colleges do carry on research activity oriented toward its instructional values and with salutary results. Many more colleges could do so.

The use of research as a means of supplementing undergraduate instruction in science is limited for several reasons. First, some faculty members in smaller colleges seem, perhaps for reasons of prestige, to be more interested in research for its own sake than for its instructional value. Because they are typically in a less favorable position to conduct original research, they are not very successful when they compete for research funds. Second, many other faculty members in smaller undergraduate institutions simply are not convinced of the instructional value of research either for themselves or their students. They are not aggressive in starting those research activities which would be possible even within the limits of their own competence and available facilities. Third, many college teachers are so inexperienced in research that they are unable effectively to utilize research as a supplement to instruction. Fourth, there is relatively little money available to support research activity for its instructional values.

NSF does support, through its science education activities, a substantial amount of "research participation" activity in a large number

of undergraduate institutions. There are programs for both faculty and students. The educational potential is the basis of support. With respect to the support of research per se—that is, for the discovery of new knowledge—the Foundation's research support programs have been oriented toward "quality" research. With limited funds for the support of basic research, the Foundation has to date deliberately chosen (wisely, I believe) to invest its research funds in those projects judged to have highest scientific merit. Within this framework, NSF has provided support to a substantial number of institutions that give only a few (if any) advanced degrees. For example, in fiscal year 1965, we made 92 grants to 59 colleges which grant no more than a bachelor's degree; 214 grants were made to 82 institutions that grant no more than a master's degree. As its appropriations grow, the Foundation hopes to extend its research support to include new research programs in which the instructional values play a larger part in the decisionmaking process.

The whole problem of research support in the colleges is complex and cannot be solved on any formula basis. Research funds injudiciously employed can have the effect of converting small colleges into institutions so research oriented as to have deleterious effects on undergraduate instruction. There is little danger of this happening at present, simply because there is not a great deal of research being supported in small colleges. It is the Foundation's belief that its primary role in this area is that of providing more support for faculty training in research activity and for research activity for its instructional value.

(See also E-17.)

E-21. Scientific talent in Government is concentrated, of course, in the executive branch. Do you believe that the scientific disciplines, including mathematics and engineering, should have more representation in our legislative bodies?

E-22. Has any effort been made by anyone to attract more scientists and engineers into politics? Should an attempt be made to induce technically trained people to run for public office? If so, how would we go about it?

I believe that more scientists and engineers serving in legislative bodies would be in the public interest. With the increased importance of science and technology in our national life, it is obviously desirable that those elected to public office have or develop an adequate understanding of the way in which these fields can and probably will affect the quality and "style" of our society. As legislators have come to deal more and more with scientific and technological problems, they have found it necessary to rely on professional advice and understanding which, to a large extent, comes from outside of legislative bodies. Legislators who, at the same time, are scientists or engineers would incorporate into the legislative process a more direct understanding of these problems. In suggesting that more scientists and engineers might serve—and serve well—as legislators, I do not advocate disproportionate representation of the scientific community. I have, in fact, no representation formula in mind. There is only the general notion that an increase of scientist-legislators would serve more than the scientific community: it would serve the Nation. I should also like to add that more and more legislators are becoming better

prepared for dealing with scientific and technical problems by virtue of the great effort they have put into learning and understanding science in connection with their legislative duties. Over the longer pull this process will be greatly enhanced by the intensified—and higher quality of—education in science now given in our schools, colleges, and universities to those students who are preparing for careers in fields other than the sciences.

I am not aware of any specific efforts which have been made to attract more scientists and engineers into politics. Some scientists and engineers have organized themselves so as to participate in recent national political campaigns. I should be surprised if this indication of interest in the political situation did not lead some of these individuals to seek public office. I believe it would benefit the Nation if some additional number of technically trained people sought and achieved public office, but I have no plan to offer for inducing more such personnel to enter politics.

E–23. Just how does the Foundation select universities and colleges for institutional support? What factors are evaluated besides educational merit? Is any consideration given to such things as geographical location; to the economy of the area—for instance, agricultural versus industrial; to climate, or population density or political status?

Institutional support from the National Science Foundation includes three programs, namely, the science facilities program, the institutional grants program, and the science development program. Also, the undergraduate instructional scientific equipment program is institutionally oriented, though at the departmental level.

Eligibility to participate in the science facilities program is limited to institutions offering graduate science degrees. In addition to making a case for the merit of the work to be done using the facility in question, the institution must demonstrate immediate need to maintain or increase its existing strength or improve its present quality of research and education. Matching on at least a 50–50 basis [1] from non-Federal funds is required. The science facility proposal submitted by an institution is evaluated in minute detail by the Foundation. A site visit team, made up of consultants and National Science Foundation staff, visits the institution. The recommendations made by the staff and the consultants are reviewed at several levels within the Foundation and, finally, the selection of the institution to receive a science facilities grant is made by the Director, his decision in the most expensive cases being subject to approval by the National Science Board. While there is no stated requirement to distribute funds on a regional basis, consideration is given to such items as the number and quality of science students in an area. During the past 6 fiscal years, science facilities grants have been made to institutions located in 49 States, Puerto Rico, and the District of Columbia.

In the institutional grants for science program, any institution receiving NSF grants for research (and/or research participation) is eligible to apply. The amount of the grant is determined by applying a formula to the total amount of such grants during a 12-month period. The formula provides for 100-percent matching of the first several thousand dollars of the base, and tapers sharply thereafter.

[1] In practice, the institutions "overmatch" to a substantial degree.

This tends to favor the smaller institutions and results in a widespread distribution of grant funds. In 1965, 376 colleges and universities in all 50 States, Puerto Rico, and the District of Columbia received institutional grants.

In the science development program, any institution of higher education granting the baccalaureate or higher degree in science or engineering is eligible to apply if it feels its present strength is such that within a 3- to 5-year period it can achieve high quality in some substantial portion of its science programs by receiving a science development grant. (Institutions having already attained positions of recognized excellence in their science programs are requested not to apply for these funds since they can and do compete successfully in other Federal programs as a means of maintaining their status.) When a science development proposal is submitted to the Foundation, it undergoes extensive evaluation by many individuals in the Foundation; it is reviewed by several scientists from outside the Foundation; the institution is site-visited by a team made up of Foundation and non-Foundation personnel; meritorious proposals are presented to a Science Development Advisory Panel, who make recommendations to the Director; a special Science Development Program Committee of the National Science Board advises with the Director in reaching a final decision to make a science development grant. The 10 institutions receiving science development grants to date are located in widely separated geographic areas. While no formal requirements or formulas have been instituted to assure regional distribution, this is clearly recognized as an important element. While there is recognition that a major grant has an impact upon the economy of an area, there have been no guidelines set up for utilizing this factor as more than a general subjective element in the decision process.

The undergraduate instructional scientific equipment program considers proposals from:

Type 1. Colleges and universities in the United States and its territories offering a baccalaureate in one or more of the sciences or in engineering.

Type 2. Other 4-year institutions, as well as junior and community colleges offering freshman and sophomore course in the sciences acceptable for transfer credit to a 4-year college or university granting a baccalaureate in one or more of the sciences.

In selecting proposals for support, the Foundation staff is assisted by panels of scientists drawn from the academic community, research organizations, and professional scientific societies. The recommendations of these panels form a major element in the Foundation's determination of whether a grant will be made. Support by order of merit to the extent of available funding is the rule except that in cases of substantially equal merit, consideration is given to other factors such as disciplinary, institutional, and geographical distribution.

E–24. What steps has the Foundation taken in response to the 1960 report of the President's Scientific Advisory Committee which advocated the development of additional centers of academic excellence? Has there been any effective geographical dispersal of institutional support of our institutions of higher learning?

One response to the President's Science Advisory Committee report, dated November 15, 1960, and titled "Scientific Progress, the Universities, and the Federal Government," [1] was the expansion of the graduate science facilities program for the purpose of increasing "the quality and quantity of research results and the number of trained scientists."

Requiring much longer study by the Foundation was a response to the recommendation for "an increase in the number of universities in which first-rate research and graduate teaching programs are present." In preparing to initiate such a science development program many things were done. The National Science Board discussed the question at length on numerous occasions. A special "science development committee" (comprised of senior members of the Foundation's staff) visited several institutions to discuss institutional needs. Institutional development ideas were discussed with NSF Divisional Committees.

In March 1964, the Foundation announced its science development program for colleges and universities. In my foreword to the announcement, the new effort's relevance to the Seaborg report's findings was acknowledged in these words: "It is generally recognized that there is a need for additional centers of academic excellence in the sciences. The President's Science Advisory Committee in its report of November 15, 1960, emphasized this need." The major objective of the science development program is to increase the number of institutions of recognized excellence in research and education in the sciences. This program's primary purpose is to accelerate improvement in science through the provision of funds to be expended in accordance with carefully developed plans designed to produce significant upgrading in the quality of the institution's science activities. Grants are made to institutions judged to have the greatest possibility of moving upward to a high level of scientific quality and to have sound plans for maintaining this quality.

The Foundation's institutional programs have not been subjected to a specific percentage distribution requirement by region. The tables on institutional grants provided in partial response to question A–21 give data by State for fiscal years 1963, 1964, and 1965 on the distribution of institutional base grants and of grants for science facilities to educational institutions. Institutional base grants are based on a formula applied to the amount of research grants an institution received in a 12-month period, and science facilities grants are made in response to approved selected proposals requesting funds for needed science facilities.

The science development program has been in operation 1 year and only 10 grants have been made. A table of distribution for science development grants is also provided at the end of question A–21.

E–25. Are the NSF institutional grants consistent in policy and content with those of National Institutes of Health, NASA, and other Federal agencies? What is the amount of private sector support in the same programs?

---

[1] More commonly designated as "The Seaborg Report."

I. POLICY AND CONTENT

There are several Federal programs of "institutional grants" of one kind or another, as, for example, the formula grants for agricultural research to agricultural experiment stations under the Hatch Act and the formula grants for operational assistance to schools of public health. The Federal programs most nearly comparable in NSF's institutional grants for science, however, are NIH's general research support program and NASA's sustaining university program.

The NSF, NIH, and NASA programs are consistent in their policy of relying upon the responsibility, creativity, and initiative of higher educational institutions to achieve national goals in science. All three programs under discussion provide Federal grants to institutions as such, rather than directly to individual investigators. The programs rest upon the assumption that strong and effective educational institutions are indispensable for the fulfillment of the missions of the agencies. Therefore, some rather broad support of institutional scientific activities is in the national interest and in the interest of the supporting agencies. The programs allow a considerable degree of local judgment in the making of decisions and of flexibility in the use of grant funds; in this way, they permit the grantee institutions to meet some of their particular needs in science and to take advantage of some of their unique capabilities.

The purposes of the three programs are similar, although those of NIH and NASA are necessarily tied to health-related and space-related sciences, respectively.

The purpose of the NIH institutional grants has been stated as follows:

> The purpose of the general research support grant is to provide funds on a continuing basis to eligible institutions heavily engaged in health-related research and research training for their flexible and discriminating cultivation of disciplines of science relating to health. This grant permits institutions an increased measure of control over the quality, content, emphasis, and direction of their research activities. It permits them to meet emergency opportunities in research, to explore new and unorthodox ideas, to recognize and support scientific talent earlier, and in general, to utilize funds flexibly and in ways that will be catalytic for fostering additional research capabilities and for attracting additional means of research support. ("General Research Support: A General Policy and Information Statement," pt. 1, revised September 1963, National Institutes of Health, p. iii.)

The Director of NASA's Office of Grants and Research Contracts has described the purpose of the NASA sustaining university program as follows:

> The sustaining university program has been designed as an integrated program encompassing the support of training, research, and research facilities in a manner that will augment and complement sponsored project research and in-house activity in support of NASA's mission. We consider it essential to develop a strong, mutually interdependent relationship between NASA and the universities in working to fulfill the needs for scientific manpower and research in the Nation's space program. (T. L. K. Smull, "The Nature and Scope of the NASA University Program," National Aeronautics and Space Administration, 1965, p. 38.)

The announcement entitled "Institutional Grants for Science, 1965," states the purpose of the NSF program:

* * * Institutional grants * * * are intended to assist colleges and universities in the development and maintenance of strong, well-balanced programs of research and education in the sciences. Institutions may use their own judgment as to the most effective employment of institutional grant funds, with the limitations that the funds must be used for science (including mathematics and engineering) and may not be expended for indirect costs * * *.

The Foundation recognizes that institutions of higher education are in a position to determine the best means for strengthening their scientific programs. Accordingly, responsibility for the administration of an institutional grant for science rests with the grantee institution. The Foundation wishes to avoid any action that might diminish the autonomy of the institution and its responsibility for making sound scientific and administrative judgments * * *.

* * * The funds may be used for scientific research, for education in the sciences, or for both. Existing activities may be supplemented or new ones initiated with the funds made available by the grants.

Some differences in the three programs arise not only from the differing missions of the agencies but from the types of institutions to which they make their institutional grants. Most NIH grants of this nature are made to educational institutions in the "health-professional school" category (apart from certain noneducational institutions which also receive general research support grants); thus, several general research support grants may be made to component parts of a single university. NASA's grants under the sustaining university program are made to large and small universities with graduate programs. NSF's institutional grants are made to colleges and universities (513 during the years 1961–65), many of them liberal arts institutions granting only baccalaureate degrees; medical and other health-professional schools that are parts of universities and 2-year extension centers of universities are not separately eligible for NSF institutional grants.

The budget for the NSF program is much smaller than that of either of the other two agencies. In fiscal year 1965 the budget for NIH's general research support program was approximately $44 million; for NASA's sustaining university program, $46 million; for NSF's institutional grants program, $11 million.

NIH's general research support grants and NSF's institutional grants are computed by arithmetical formulas. The base to which the formulas are applied is for both agencies a "research" base, although since 1963 the NSF base has included grants under two NSF research-participation (i.e., educationally oriented) programs as well as NSF grants for research projects. The NSF formula favors "small" institutions by dollar-for-dollar matching of the first $10,000 of the base, by tapering the formula thereafter, and by setting an upper limit on the total amount of the grant. The NIH formula also has been based in part on the principle "that institutions with small research programs should receive relatively greater general research support than those with more extensive research activities." ("The General Research Support Program of the National Institutes of Health: A Report of a Study by a Committee of the Division of Medical Sciences, March 31, 1965," National Academy of Sciences—National Research Council, p. 18.) NIH also fixes an upper limit for its general research support grants, although the maximum has been substantially higher than NSF's. (The maximum NSF grant in-

creased from $37,500 in 1961 to $150,000 in 1964; in 1965, the largest grant was for $146,624. The maximum NIH grant was $452,000 in 1964 and $585,000 in 1965.)

One important difference between the two formula-grant programs is the nature of the "base." NSF institutional grants have been computed from a base made up of the total of NSF grants for basic research, undergraduate research participation, and research participation for college teachers to an institution during the 12-month period ending March 31. NIH, however, has based its general research support grants on health-related research expenditures by institutions from funds derived from "Federal research grants and contracts restricted for research" and from funds derived from "non-Federal grants, contracts and gifts restricted for research." Two different formulas are applied to these different (Federal and non-Federal) elements of the base, with the heavier weighting being given to the non-Federal portion. Four types of health-professional schools (medicine, dentistry, osteopathy, and public health) are automatically eligible for base grants of $25,000. Other types of health-professional schools, as well as separate research institutes, laboratories, hospitals, etc., may qualify for general research support grants if they have received a minimum of $100,000 of NIH research grants during the 12-month period ending June 30; only educational institutions may qualify for the base grant of $25,000.

Thus, the NSF base has been made up only of NSF grants. The NIH base consists not only of expenditures from NIH research grants but from those of other Federal agencies (including NSF) and non-Federal research grants.

NSF institutional grant funds may not be spent for indirect costs. Until 1965 the NIH general research support grants contained an allowance for indirect costs expected to be incurred by institutions in the conduct of research and research training under the grants. (This allowance was 15 percent of the basic award in the first year of the program, 20 percent thereafter.) In authorizing funds for the 1965 NIH program, however, Congress prohibited payments for indirect costs in the general research support program.

Both the NSF and the NIH grants allow a great deal of flexibility in the use of funds. Both agencies, of course, require reports from institutions on the use of grant funds, and these reports are carefully scrutinized to see that institutions have used the funds for allowable purposes.

II. PRIVATE SECTOR SUPPORT

The second question posed in E–25 might be rephrased to read: "Is support provided to institutions by private individuals, foundations, industry, etc., in the form of flexible-use institutional grants for science?"

Within the private sector, private philanthropic foundations—including company-sponsored foundations—and voluntary health agencies grant unrestricted funds for the overall development of universities and colleges. Grants of this type from these organizations are not strictly comparable to the NIH and NSF "institutional grants" described above, since they are not based on percentage formulas such as overall support of certain research and science education programs

in educational institutions. Also, unrestricted grants by private foundations and voluntary health agencies are extended for the general development of universities and colleges and may be used for any purpose that will advance educational aims, such as construction of facilities, research, and studies in all educational fields. Some of these unrestricted grants are in the form of matching funds where the educational institutions are required to match the grants in various ratios with funds raised from other sources.

Although exact data are not available for the total amount of unrestricted grants extended by private foundations and voluntary health agencies to universities and colleges, it is estimated that this amount was probably somewhat in excess of $50 million in 1964. This estimate does not include the funds given to universities and colleges by private individuals and industrial firms for the general support of education.

E-26. How does the Federal Interagency Committee on Education operate? How often has it met? What policy issues has it studied and acted upon?

Since the Federal Interagency Committee has met only once, it is not possible at this time to describe its mode of operation. It has begun to study Federal expenditures in education but has not discussed or acted upon any policy issues.

It is probable that the Federal Interagency Committee will not really get into action until an executive secretary (or equivalent) can be recruited. I understand that Commissioner Keppel is currently seeking a suitable person to assume this role.

F. National Research Programs of NSF

F–1. How does a project achieve the status of a national research program?

A national research program receives this designation where the Director of the Foundation, with the concurrence of the National Science Board and the Bureau of the Budget, specifically requests funds for its support from the Congress. If funds are then appropriated which may be used for the program, it comes into existence as an operating entity. Much planning and preliminary research may be supported prior to this time, but the major effort is not initiated until funds have been appropriated for the budget year in which the newly proposed activity is presented to the Congress.

F–2. Many of the programs which NSF supports originated in the National Academy of Sciences. Can you trace by explicit examples—i.e., the antarctic research program, Project Mohole, international upper mantle project, International Years of the Quiet Sun, and the International Biological Year—the manner in which proposals were reviewed by the Foundation, the Science Board, PSAC, OST, and the Bureau of the Budget, up to the time they were included in submissions to the Congress?

Many different groups have been interested in the development of programs, such as the antarctic research program, Project Mohole, International Upper Mantle Project, International Years of the Quiet Sun, and the International Biological Year. In most of these instances ad hoc or special committees of the National Academy of Sciences considered the needs and opportunities in these areas of science. As a result, the Academy has had an important impact on many of the Foundation's programs. This is particularly true of programs calling for a major national and interdisciplinary effort on the part of the scientific community. These committees issued reports which presented the nature of the problem from a scientific point of view and also provided estimates of funds which would be required in order to carry them out. These reports were in most cases sent or submitted to the Foundation and to the Office of Science and Technology. In reviewing these reports, the Director has of course had the advice of the National Science Board, and (since 1958) has been able to confer on such matters with the Special Assistant to the President for Science and Technology. As a result of these coordinative efforts, and if it was agreed that a proposed program held great promise, the fiscal needs for such a program were placed before the Bureau of the Budget. After review by the Bureau and approval of funds by the President, the program was begun. In the following examples an effort is made to trace the origin, development, and management of several such programs.

ANTARCTIC RESEARCH PROGRAM

The program for the International Geophysical Year (IGY), for which the National Academy of Sciences held a major degree of responsibility, included a research effort in Antarctica. Recognizing that the period set aside for the IGY was insufficient for the accomplishment of the scientific objectives in Antarctica, the Academy recommended to the Foundation that the program be continued for at least an additional year. Concurrently, the U.S. Government, aware of these recommendations, reviewed the commitment the United States had in Antarctica. An Executive decision was made in 1957 to continue U.S. activities in Antarctica on a long-term basis. It was further decided at the Executive level that the National Science Foundation would assume the responsibility for planning, coordinating, and funding an integrated research program in Antarctica with the Department of Defense funding and supplying the necessary logistic support. (In toto, the actual magnitude of the Department of Defense contribution is greater than that of the Foundation.)

On January 24, 1958, the Director of the Foundation, in testimony before the House Committee on Interstate and Foreign Commerce, announced the plan to continue U.S. antarctic scientific programs beyond the IGY. Similar announcements were issued by the White House and the Department of the Navy. On February 5, 1958, the National Academy of Sciences responded to the Foundation's request of January 17, 1958, for advice in developing a comprehensive antarctic research effort by establishing the Committee on Polar Research, chaired by Dr. Laurence M. Gould.

Correspondence was simultaneously exchanged between the Director of the Foundation and the Secretaries of Commerce, Interior, and Defense establishing concurrence that the Foundation go forward to obtain a single budget and appropriation for the support of the "post-IGY" program. The budget initially suggested by the Academy to the Foundation was $4.3 million, but because of policy and the limitation on logistic support that the U.S. Naval Support Force, Antarctica, could provide for the scientific program in the coming year, the Foundation reduced the budget estimate to $2.435 million and a request for a supplementary appropriation was submitted to the Congress.

The House Committee on Appropriations, in considering the bill, struck out the entire amount, which the Senate restored. On May 12, 1958, the conference committee approved $2 million for the entire research program, $1 million of this amount to be new money appropriated by Congress and the remaining $1 million to be absorbed by the Foundation from its regular 1959 appropriation.

Subsequently, the interagency arrangements for the planning and management of the U.S. antarctic research program were formalized by issuance of the Bureau of the Budget Circular A–51 of August 3, 1960 (see the response to question F–8).

Within the Foundation, the responsibility for handling the organization of the antarctic scientific program (and its coordination with the logistic operations of the U.S. Naval Support Force, Antarctica) was assigned to the antarctic program in the Office of Special International Programs. The management authority for U.S. scientific activities in Antarctica was thus transferred from the Academy to

the Foundation. Subsequently this unit in the Foundation became the Office of Antarctic Programs.

The Committee on Polar Research of the National Academy of Sciences continues to provide the Foundation with recommendations on broad program content and undertakes from time to time specific tasks of an advisory nature related to antarctic scientific exploration. In 1961 the committee prepared and submitted to the Foundation a long-range analysis of scientific objectives (NAS-NRC Publications 839 and 878). The committee also represents the Academy and the U.S. scientific community with antarctic interests on the Scientific Committee on Antarctic Research of the International Council of Scientific Unions.

PROJECT MOHOLE

The Mohole project was proposed by the National Academy of Sciences. The first proposal in March 1958, called for a feasibility study and, during that year, the Foundation granted funds for such a study. The work was done by the Amsoc committee—the official Academy committee formed to carry out the project—and its staff. This initial study provided data and information which demonstrated that with current advances in technology and with some adaptation of existing drilling equipment, it might be feasible to drill through the crust of the earth and sample the underlying mantle.

With funds provided by the Foundation, the Academy assembled a staff, and phase I of the project was successfully carried out. Phase I concluded with the drilling of several shallow holes into the Pacific Ocean floor in water approximately 12,000 feet deep from a dynamically positioned oil drilling barge. Cores were recovered from beneath the ocean floor providing material for new scientific studies. Several scientific and technical papers resulted.

When the plans to carry out phase II of the project were formulated—the actual attempt to drill through the crust—the Academy committee recommended that this phase be carried out directly by the National Science Foundation under contract. The contract would provide for the entire effort—management, engineering research, development and design, and operations. The project has proceeded in this manner.

The Mohole project from the beginning has received the attention of the Director of the National Science Foundation and his top staff. In its conceptual stage, the project was carefully considered by the National Science Board and the President's Science Advisory Committee. Every major step in the project has been reviewed with the National Science Board, and no funds have been obligated without first obtaining the Board's authorization. Reports have been made to the Bureau of the Budget in the course of the regular budgetary process, and special reports have been made to the Bureau of the Budget and the Office of Science and Technology in working out funding pursuant to the sense of the conference report accompanying the fiscal year 1964 appropriations act.

THE INTERNATIONAL UPPER MANTLE PROJECT

The international upper mantle project originated not at the National Academy of Sciences but in the International Union of Geodesy

and Geophysics. It was proposed by Academician V. V. Beloussov of Russia at the 12th General Assembly of the Union at Helsinki in 1960. A resolution was passed endorsing Beloussov's suggestion, and scientists from various member countries started planning for the work.

In the United States the National Academy is the adhering body for international scientific unions. The Academy, therefore, through its Geophysics Research Board, set up a panel to outline a realistic program for the U.S. participation. The plan, which was issued in 1962, recommended a program for the U.S. participation in the upper mantle project that would involve work by the U.S. Geological Survey, U.S. Coast and Geodetic Survey, Advanced Research Projects Agency through its Vela program), and universities. It was recommended that the universities seek support for their work from the National Science Foundation.

Strictly speaking, the upper mantle project has never been formally declared a national program, although both the present and previous administrations have endorsed the activities connected with the project. The Foundation has never received a proposal for funds simply to "support part of the upper mantle project." Instead, various university projects that are considered to be part of the U.S. effort are submitted as regular research proposals to the Foundation and compete with all other research proposals in the earth sciences. In other words, there is no special sum allocated by NFS for use in support of the upper mantle project, and every successful proposal must be judged worthy of support in competition with other research proposals received by the Foundation in order to receive a grant.

Activities in connection with upper mantle studies have been cited in our budget request, but no line item has been sought.

INTERNATIONAL YEARS OF THE QUIET SUN

The International Geophysical Year (IGY), and the following International Geophysical Cooperation (IGC), taking place during a solar cycle maximum of unique intensity, revealed unexpected and challenging phenomena that clearly demonstrated the need for a specific coordinated program of special scientific research during the subsequent solar minimum; as a consequence, interested scientists proposed the International Years of the Quiet Sun (IQSY). The period was set as the 24 months beginning January 1, 1964.

In recognition of the international nature of this task (and because of the consequent need for a national group to coordinate U.S. efforts with those of other nations), the National Academy of Sciences established the U.S. Committee for the IQSY to accomplish the planning of the scientific programs. In early 1962, the National Academy of Sciences wrote to NSF seeking formal Government concurrence on the merit of the IQSY research programs.

An extensive and detailed staff analysis and review of the IQSY was undertaken within the Foundation which resulted in the decision to accept the program on behalf of the Government and to seek the formal endorsement of the President for the U.S. participa-

tion. The Foundation on July 27, 1962, wrote to the President in part as follows:

In view of the substantive values to be derived from this program and in view of the opportunity it affords the United States to promote international cooperation and to exercise international scientific leadership, the National Science Foundation recommends your endorsement of U.S. participation in the program for the International Years of the Quiet Sun. With such endorsement, and subject to appropriate program and budget review, the Foundation stands ready to include in its budget request the estimated funds required, to coordinate the Government's interests in this program, and to make arrangements with appropriate Federal and other agencies for carrying out the program.

President Kennedy responded with an authorization and emphasized the importance of NSF taking responsibility and leadership in developing the additions to the normal agency programs and in maintaining control over the size of the effort.

Concurrently with the NSF staff review the Interdepartmental Committee for Atmospheric Sciences (ICAS) formally considered Government participation in the IQSY program. ICAS recommended the program to its parent body, the Federal Council for Science and Technology.

Following receipt of the President's letter authorizing participation in the IQSY, a memorandum was prepared for the consideration of the National Science Board. It summarized the background and the scientific program of the IQSY and estimated the fiscal requirements as follows:

Fiscal year 1963	$1,000,000
Fiscal year 1964	5,000,000
Fiscal year 1965	5,000,000
Fiscal year 1966	1,000,000
Fiscal year 1967	1,000,000
Total	13,000,000

At its meeting of November 17, 1962, the National Science Board approved the U.S. program for the International Years of the Quiet Sun and delegated to the Director authority to review, approve, and take final action with respect to making grants, contracts, or other arrangements not to exceed $13 million for the purpose of providing support for the U.S. program for the IQSY.

Formal request to the Bureau of the Budget for support of IQSY as a national research program was first made in the NSF budget request for fiscal year 1964. Review by the Bureau of the Budget took place in connection with that request.

THE INTERNATIONAL BIOLOGICAL YEAR

The International Biological Year has officially become the international biological program. When it became evident that relatively little biological research was to be included in the activities associated with the International Geophysical Year (IGY) (1957–58) and the International Geophysical Cooperation (IGC) (1959), sentiment developed among a few individuals for a similar—large, varied, and

international—biological program. At first there was no great enthusiasm among working-level biologists for participation in such a movement. But a number of groups continued to advocate such an activity, and interest slowly increased.

Meanwhile the problem had been discussed by the Executive Committee of the International Union of Biological Sciences (IUBS) at their annual meetings in 1959 and 1960 and by the Executive Board of the International Council of Scientific Unions (ICSU) in the spring and fall of 1960. A proposal for organization of a biological year similar to the IGY was proposed by Prof. G. Montalenti of the Institute of Genetics, University of Rome, then president of IUBS, to ICSU which approved it in principle in October 1960. Members of the U.S. National Committee to IUBS were at this time involved in discussions of the matter.

The idea was then considered further by members of ICSU and three of its affiliated unions: the International Union of Biological Sciences; the International Union of Biochemistry; and the International Union of Physiological Sciences. At its general assembly in 1961, ICSU approved a revised version of the Montalenti plan for an international biological program, and formed a planning committee. The IBP Planning Committee held two meetings in May 1962 and January 1963 from which a general plan for the IBP emerged. Three subcommittees were also set up to facilitate planning. ICSU provided housekeeping funds for the IBP secretariat and committees. The aim was to have a final plan ready for consideration by the IUBS General Assembly in Prague in August 1964.

The National Academy of Sciences involvement dates back to IUBS involvement. NAS–NRC coordinated with and thus kept NSF advised of the course of this activity. The Academy gave NSF an opportunity to comment on the proposed selections for the ad hoc committee for the IBP it was setting up to consider U.S. participation. NSF was also invited to have observers at all meetings of this ad hoc committee and to send an observer to Paris in July 1964 at the time of the first general meeting called by ICSU to consider IBP. At Paris, the organization of the IBP was formalized. The ad hoc committee for IBP, which carried the U.S. point of view to Paris, recommended to NAS upon its return that the United States participate in the IBP. NAS accepted the recommendation and appointed a new U.S. committee for the IBP to plan and coordinate U.S. participation. NSF has monitored all these preliminaries.

From the time of the first mention of a possible large international biological program, NSF closely followed this development as it recognized it might well be approached for financial assistance. The Foundation's interest centered on the soundness of the scientific program, its feasibility, the strength of its leadership, the breadth of its appeal, and the likelihood of obtaining funds for its support. Since fiscal year 1963 NSF has been concerned with the amount of support it might be called upon annually to provide for the IBP. Through the National Academy of Sciences, NSF has provided the annual dues for U.S. participation in the IBP since they were set in 1964 and it has made the major contribution (NIH has provided the rest) toward support of the U.S. committee and subcommittees involved in planning for the IBP.

Reference was made to the IBP in our fiscal year 1966 budget justification to the Bureau of the Budget and Congress, but no special funds were requested. Any funding for IBP-related activities through fiscal year 1967 will be handled with research funds from the Foundation's project grant funds. Special budgetary treatment (akin to that for other "national research programs") may become unavoidable in fiscal year 1968 at which time the IBP will become fully operational.

Meetings called by the National Academy of Sciences in connection with the IBP have included observers from such other governmental departments and offices (in addition to NSF) as State, Interior, Agriculture, NIH, ONR, AEC, NASA, OST, etc. No one agency has as yet been assigned the overall responsibility for the IBP as is customary for international programs.

Within NSF the IBP has been discussed with the National Science Board on several occasions as well as with the Divisional Committee for Biological and Medical Sciences. At the April 1965 meeting of the latter committee, the IBP was featured on the agenda and the possible role of the NSF in the IBP was considered in depth.

F-3. What is your reaction to the series of reports and recommendations by the National Academy of Sciences with respect to needs for research in special fields?

The reports undertaken under the auspices of the Academy's Committee on Science and Public Policy promise to serve as extremely valuable sources for data and judgment and to contribute to sound policy decisions. I am pleased that the Foundation has been able to play a major role in making these reports possible by financially supporting much of the work of the Committee on Science and Public Policy. One of these reports was published last year by the Academy, that on "Ground-Based Astronomy: A 10-Year Program." Reports on chemistry, computers, and physics are scheduled for publication in the near future. Another on plant sciences has moved a long distance toward completion, and studies of mathematics and biology are being launched.

Prepared with the guidance and under the scrutiny of the Committee on Science and Public Policy, these reports represent a new stage in efforts directed toward the rational planning of longer range science policy. They can and will help illuminate for the entire scientific enterprise—including especially the Federal Government, and, therefore NSF—many problems of the short- and long-term policy with respect to research and education in the sciences. In addition, these reports offer promise in developing interagency approaches to problems of funding and program evaluation. Thus, they can assist in assuring the future health of fields of scientific activity.

It is worth noting that the involvement of significant numbers of scientists in the panel structure used to prepare these reports adds an additional dimension to their worth which is commonly overlooked. Those so involved are inevitably brought to a better understanding of both the nature and problems of science policy and of the relationship of academic research to the Nation's total scientific enterprise.

I would only note that these reports, valuable as they have been and will be for planning future needs in the scientific field that each covers, as yet provide no basis for comparisons of the relative urgency

of meeting the needs of the several fields. This problem is of continuing concern to the Foundation whose responsibilities cover the broad spectrum of the sciences.

F-4. What was the reason for assigning the weather modification program to NSF, in the 1958 amendment to the basic NSF Act, rather than to some other Government agency?

In 1953, pursuant to an act of Congress, the Advisory Committee on Weather Control was established. It consisted of the Secretaries of the Departments of Agriculture, Commerce, Defense, Interior, HEW, and the Director of the National Science Foundation (or their designees), as well as five private members appointed by the President, by and with the advice and consent of the Senate. The Committee was directed to make "a complete study and evaluation of public and private experiments in weather control for the purpose of determining the extent to which the United States should experiment with, engage in, or regulate activities designed to control weather conditions." The Advisory Committee on Weather Control rendered its final report on December 31, 1957. In the light of its study and evaluation of the public and private experiments in weather control undertaken during the 4 years of its activities, it concluded that progress in weather modification would have to rest on a firmer foundation of knowledge developed through basic research into the physical and chemical processes of the atmosphere. The Committee recommended unanimously that the Foundation, as the agency of the Federal Government responsible for supporting general-purpose basic research, should assume responsibility for the program. The Congress, with this report before it, then enacted the 1958 amendment to the NSF Act. I believe that the ongoing programs of the Foundation, together with a recognition of its close relationship with the scientific community, also were considerations which entered into the decision of the Congress.

F-5. Apart from grants for research in weather modification, what has been the Foundation's involvement in this field since 1958, relative to private and other nongovernmental operations? Does NSF plan to expand its activities in weather modification research?

Other than through its research support, the Foundation has not become involved in private or nongovernmental operations in weather modification, although NSF does require reporting of actual seeding activities to the NSF in accordance with its reporting and evaluation responsibilities under Public Law 85-510. Private industrial research groups have successfully competed for NSF weather modification research funds and are awarded contracts for the scientific research and special studies thus performed. In addition, the Foundation has sponsored technical symposia and individual travel to foreign scientific meetings in which members of private or nongovernmental groups have participated. The NSF does not plan to assume any regulatory or coordinative function with any private or nongovernmental group since such authority is not given under Public Law 85-510 and is not consistent with the Foundation's mission in research and education. The NSF will, however, shortly require any individual or organization, whether commercial or nonprofit, to report to it in advance any plans for field activities to modify the atmosphere and will require monthly progress reports during the conduct of such field operations.

With regard to budget plans, the Foundation increased its allocation of funds for weather modification research from $1.5 million in fiscal year 1964 to $2 million in fiscal year 1965. It is planned that the $2 million level will be held during fiscal year 1966. Hopefully, the level will be increased in fiscal year 1967. Indeed, we foresee a need to substantially increase the Foundation's budget for weather modification research in future years; however, I believe that determination of the scale of this increase should await the report of the Foundation's Special Commission on Weather Modification which is now considering this entire problem.

F-6. A recent report of the Government Operations Committee stated that the current status of coordination of weather modification is not clear, and that both the NSF and Interdepartmental Committee for Atmospheric Sciences of the Federal Council for Science and Technology claim coordinating responsibility. Would you explain the relative coordinating responsibilities of each? What are the duties of each insofar as the evaluation of research is concerned?

The National Science Foundation does not claim program coordination responsibility in weather modification, since this authority was not conferred on the Foundation by the act of July 11, 1958, Public Law 85-510. The act especially directs the Foundation to "initiate and support a program of study, research, and evaluation in the field of weather modification * * *." As its first task, the Foundation undertook the encouragement and the building up of the widest possible competent research in the fields of meteorology related to weather modification, such as laboratory cloud physics, experimental cloud physics, including the use and development of cloud seeding techniques, and the design and evaluation of weather modification experiments through use of advanced principles in statistics and physical meteorology.

Therefore, under the authority of the act, the National Science Foundation assumed a leading role in the support of weather modification research. The research is accomplished by contract with or by grant to private or public institutions. The Foundation also consults with meteorologists and scientists within Government agencies and outside the Federal Government who are interested in or affected by weather modification research. Several of the Federal departments and agencies also conduct weather modification research projects that bear directly upon their statutory missions.

The act also requires the Foundation to submit an annual report on weather modification to the President and the Congress. In order to obtain the necessary detailed technical information on the progress of research sponsored by other Federal agencies, the National Science Foundation convenes the Interagency Conference on Weather Modification each year, which is attended by working level research scientists and research administrators. The Conference leads to an evaluation of the progress made on the research projects of each participating group, and the working scientists are encouraged to enter into joint project relationships and share the technical facilities and capabilities across departmental or agency lines on a voluntary basis. Proceedings of the Interagency Conference on Weather Modification are distributed to the Conference attendees. Elements are abstracted

for insertion in the annual report on weather modification to the President and the Congress prepared by the Foundation.

The Interdepartmental Committee for Atmospheric Sciences has the responsibility to coordinate all of the atmospheric sciences, including weather modification research. ICAS is attended by policy level persons and coordination is accomplished at the program and budget review level across the departmental and agency lines. ICAS initiates studies on national requirements in areas of the atmospheric sciences and recommends the initiation or modification of programs through the Federal Council for Science and Technology. ICAS does not conduct a detailed project-by-project review, such as that undertaken by the Interagency Conference on Weather Modification.

With regard to evaluation, the NSF fully evaluates all research projects which it considers for support, including requests for transfer of funds to support other Federal Government projects in weather modification. The evaluation process continues for the duration of the support period. ICAS, on the other hand, evaluates programs and policies in weather modification on a broad Federal level in connection with its budgetary review procedures and the coordination of atmospheric sciences programs.

F–7. Does the Foundation coordinate, or is it aware of, the activities of commercial weather modification firms? Is the Foundation planning to expand its activities in this area? Suppose some of these commercial firms do not wish to cooperate with the Foundation, has or would the Foundation use its subpena powers set forth in section 14(f) of the NSF Act?

Under the provisions of Public Law 85–510, the NSF is directed, "to initiate and support a program of study, research, and evaluation in the field of weather modification * * *." Since coordination would require the power to regulate or deny permission to a cloud seeder to perform the services for which he has been hired by his sponsor, the NSF does not interpret the coordination of the activities of commercial weather modification firms as being implicit in the authority to evaluate their activities. The Foundation does require that each commercial cloud seeder report his activities to the NSF upon completion of the field operation using a BOB approved form, 9B–13, supplied by the Foundation. These records have been maintained by the NSF on a yearly basis since 1959.

The Foundation is preparing a regulation for issuance under the authority of Public Law 85–510 which will require all weather modifiers, whether Government, university, or privately supported, to report to the NSF their intention to seed or otherwise modify the weather prior to actual field operations and to report their operations to the NSF every 30 days during the field operational period. In addition, the regulation will require that each seeder maintain a written log for a stated period of years, and that this log be made available to the NSF upon demand during that period. In event that any cloud seeder refuses to comply, the Foundation is prepared to invoke the subpena powers set forth in section 14(f) of the NSF Act if such action appears appropriate.

F–8. In the Antarctic research program, the NSF maintains a 266-foot research vessel and four mainland stations. Does the Foundation operate those under contract with an outside group? If not, does this

conflict with section 15(c) of the NSF Act, which provides that "the Foundation shall not, itself, operate any laboratories or pilot plants"?

By executive agreement, prior to the initiation of the International Geophysical Year, the principal logistic support for the construction and operation of Antarctic stations was assigned to the Department of Defense and delegated to the Secretary of the Navy. The responsibility for directing the scientific programs rested in the National Academy of Sciences. Under Bureau of the Budget Circular A-51, dated August 3, 1960 (copy attached), the Department of Defense continues to bear the responsibility for logistic support, including station operation, with the Foundation responsible for the scientific programs.

The Antarctic stations, Byrd, McMurdo, Palmer, and Pole, are operated and maintained by the U.S. Navy by executive agreement, as noted above. The Foundation does not operate these stations. The research at these stations is carried on by university and agency scientists under grant or transfer of funds from the Foundation. In the case of the *Eltanin*, the ship is operated for the Foundation by the Military Sea Transportation Service and the scientific programs aboard are, in the same manner as at the stations, carried out under grant or transfer arrangements between the Foundation and university or agency, as appropriate.

At the stations on the continent and on the *Eltanin*, certain phases of the support to the scientists and the maintenance of specialized laboratories are performed under contracts with organizations experienced in these matters.

(BOB Circular A-51.)

[Circular No. A-51]

EXECUTIVE OFFICE OF THE PRESIDENT,
BUREAU OF THE BUDGET,
Washington, D.C., August 3, 1960.

To: The heads of executive departments and establishments.
Subject: Planning and conduct of the United States program for Antarctica.

1. *Purpose.*—This circular provides the basis for the planning, budgeting, management, and conduct of the United States program for Antarctica.

2. *Policies.*—The following general policies are to be observed by the Federal agencies concerned:

(*a*) The National Science Foundation shall continue to exercise the principal coordinating and management role in the development and carrying out of an integrated U.S. scientific program for Antarctica. Agencies shall cooperate with the Foundation in this regard through the appointment to advisory committees of policy level or other agency representatives as may be requested by the Director of the National Science Foundation.

(*b*) The Department of Defense shall continue its role with respect to the planning and carrying out of operations in support of the scientific or other programs in Antarctica. The commander of the military support force shall continue to be the senior U.S. representative in Antarctica. He shall have reponsibility for determining the feasibility of, and insuring the success and safety of, Antarctic operations while making all reasonable efforts to provide the support necessary to fulfill the objectives of the Antarctic programs.

(*c*) While no central depository for Antarctic records is required, the National Science Foundation shall serve as the clearinghouse and source of information regarding the existence and location of Antarctic records, files, documents, and maps maintained within the various executive agencies and nongovernmental organizations.

3. *Role of the Operations Coordinating Board in the overall review of Antarctic activities.*—The Operations Coordinating Board serves as the coordinating agency for the totality of Antarctic activities and reviews each year's operations plan for Antarctica on a schedule coordinated with the budget cycle.

4. *Relations of the National Science Foundation to other organizations in the planning of an integrated U.S. scientific program for Antarctica*—

(*a*) The Director of the National Science Foundation may consult with interested Federal agencies and with non-Federal organizations, to the extent he considers desirable, in the development by the Foundation of an integrated U.S. scientific program for Antarctica.

(*b*) Federal agencies interested in scientific activities for Antarctica, either to be conducted by their own staffs or by other agencies and personnel, should inform the National Science Foundation of their interest and of the content of proposed scientific activities that might be included in the U.S. scientific program to be developed and funded by the Foundation.

(*c*) The National Science Foundation shall advise the Department of Defense as to its plans for scientific programs for Antarctica in sufficient time and in sufficient detail for the Department of Defense to develop the required supporting program on an orderly basis. The Department of Defense shall, in consultation with the National Science Foundation, develop a logistic program to support the U.S. scientific program for Antarctica.

(*d*) The Foundation shall continue to make allocations to Federal agencies and grants and contracts to non-Federal organizations, as it considers appropriate, to carry out the U.S. scientific program for Antarctica.

5. *International cooperation in Antarctic programs.*—The National Science Foundation, in consultation with the Department of State, shall coordinate and arrange for the conduct of cooperative scientific programs with other nations participating in the Antarctic.

6. *Budgeting and financing of Antarctic activities*—

(*a*) The National Science Foundation shall continue to plan for and request all funds for an integrated U.S. scientific program for Antarctica, including such mapping activities as are related to the scientific program, but excluding logistic support as provided for below. The Foundation shall continue to present each year to the Bureau of the Budget as an identifiable part of its regular budget submission its recommendations as to the content and cost of the U.S. scientific program for Antarctica.

(*b*) The Department of Defense shall continue to fund the logistic support for scientific and other Antarctic activities. The Department shall present each year, as part of its budget submission to the Bureau of the Budget, a statement covering the estimated costs of its support of the Antarctic operation. This statement shall cover the past, current, and budget years.

By direction of the President:

MAURICE H. STANS, *Director*.

F–9. What is the objective of Project Mohole and what benefits will be achieved by the successful completion of the project? What is the present status of the project?

F–10. With regard to Mohole, (a) When do you expect the successful bidder on construction of the platform to be announced? (b) What are Foundation's plans and prospects for having scientific guidance of the project moved outside of the Foundation? (c) In view of the increasing estimates of cost recently submitted to the Senate, is the Foundation considering a review of the merits of this project against other scientific programs of possibly higher priority?

F–11. Some of the technical problems which have affected the Mohole project are the stabilization of the drilling platform, achieving a means of getting the drill back in the hole after it has been removed, and the reduction of forces exerted on the drill string. (a) What success has been made to date in solving these problems? (b) What is the greatest depth to which deep sea drilling has been successfully demonstrated to date? (c) What depth will be required to pierce the mantle?

F–12. When the mantle of the earth is pierced, what will then become of the project? When is the project expected to be completed?

F–13. To date, what has been the total amount appropriated and the total amount expended for Project Mohole, including both phase I

and phase II? (a) What is the total estimated cost of the drilling platform including equipment? (b) What is the estimated total run-out cost of the project up to the time the mantle is pierced?

Because these five questions are so closely related, I have attempted to provide in what follows an integrated discussion which, we believe, deals with each of the points raised.

While it is well known that the most difficult objective of Project Mohole is to drill through the earth's crust and on into the next region called the mantle, we consider this project as but one aspect of a program with a much broader aim of exploring the sea floor by deep drilling in as many of the world's oceanic regions as possible. Drilling to the mantle is a difficult engineering feat. For this and other reasons this aspect has caught the attention of the public and has tended to dominate the "image" of the program as a whole.

Placing the program in its proper perspective, we may state that the Mohole project will lead the way toward opening the deep portions of the earth to the direct scrutiny and analysis of scientists. Because it will be an engineering and scientific first, involving large and complicated equipment, it will be expensive, but it has the broad and important objective of studying the earth directly as a planet rather than as a continent or an ocean, a deep sea canyon or a high mountain peak. We are at the beginning of planetary exploration and it is important that the earth also be studied as a body in space.

Eighty-five percent of the earth lies in the mantle beneath the crust. By studying and understanding the mantle, the forces at work there, its chemical composition, its age and, hopefully, its origin, we can for the first time truthfully say that we are beginning to understand the earth. It is this understanding that the Mohole program through years of work will eventually bring about.

Since we eventually hope to sample the mantle, perhaps in several places, the work must be done at sea where the crust is thin enough to penetrate. With this aim in mind there has been designed a large, stable, free-floating drilling platform that will maintain its position without anchoring in very deep water (as much as 18,000 feet) for long periods of time—as much as 2 to 3 years. The required accuracy of position cannot be achieved by anchoring at such depths.

Thus the present phase of the project should be thought of as one in which we are attempting to design and construct a major facility capable of drilling to great depths, including reaching to the mantle. Once acquired, this facility will be used as a research tool for many, many years, and merely, as many people erroneously suppose, to drill a single hole.

The benefits to be achieved by the program, so far as we know them today, are largely scientific. However, there are engineering benefits that will undoubtedly result.

So far as science is concerned, first we hope to obtain a better determination for the age of the earth since the mantle comprises 85 percent of the volume. Current age determinations are made from surface rocks which make up less than 1 percent of the earth's volume. Second, the old geologic question of whether the continents have drifted apart may be also partially answered by sampling the crust under the deep sea. If a thick section of sedimentary rocks is found beneath the sea, we can say that the ocean basin has been present for as long

as the sediments are old, and that the continents may not have drifted by sliding over the mantle's surface. Third, we hope, as well, to determine the chemical and physical nature of the mantle. The distribution of the elements in the earth and the surrounding universe is of prime interest to astrophysicists, geochemists and geophysicists. Scientists in these fields and others have always been interested in the origin of the planets and the universe and look for their clues in the physics and chemistry of nature. Basic to this is the distribution of the chemical elements in the earth and universe, how they are combined, and how the elements are made by new and evolving stars. The best base the scientists have from which to work is their knowledge of the earth, and they do not know the distribution of the elements in the mantle or in what way they are combined there. Thus our yardstick—the earth—for measuring the distribution of the elements in the universe is inadequate. Fourth, the related sciences of biology and paleontology will also benefit from sampling continuously through the sediments of the sea, however thick they may be. It is hoped that remnants of previously unknown early forms of life will be discovered that will fill in some of the gaps in our knowledge of the evolution of life on this planet. Fifth, there are, in addition, many other scientific benefits of equal importance that will derive from the project. The density of deep crustal and mantle material may be directly related to the speed of propagation of seismic waves and to gravitational accelerations. The rate of heat flow from the earth can be measured in the mantle, and further clues obtained on the origin of the heat. Information will be collected on the rates of sedimentation, and on the processes at work that form hard rocks out of sediments. Last, but not least, from all such studies will come information that will help to determine the origin of continents and, hopefully, will help as well with the problem of determining the origin of the earth.

The engineering benefits to be derived from the project are straightforward. Of primary importance is the large, floating, stable platform, dynamically positioned for drilling in very deep water. This platform will have other uses besides drilling at sea. It can also be used for implanting equipment on the deep sea floor or removing it. Platforms of this type can be used for satellite and missile tracking in areas where it is impossible to install land stations. The platform can be used for almost any other type of heavy work at sea, and should be useful for all these purposes for at least 20 years. It is reasonable to discount the high cost of the platform somewhat because of its longevity and great usefulness.

Secondarily, a few examples, and there are others, of individual engineering accomplishments may be cited that eventually will become beneficial spinoffs to the offshore drilling industry: (1) the turbocorer radial thrust bearing redesign and relocation has increased the expected life of this device by about 100 percent as demonstrated by test drilling in Texas. (2) It now appears probable that a wire line retractable bit can be successfully designed for both standard rotary drilling and turbocorer drilling. This will obviate the necessity for pulling great lengths of drill stem in order to change bits, since the retractable bit can be pulled out and replaced through the hollow drill stem. (3) An automated and programed system for handling

drill pipe and casing has been designed. This speeds up the drilling operation and will result in great saving in time and reduce the danger to personnel working on the drilling platform. (4) The fabrication problems of manufacturing titanium drill stem are under study. Titanium, while more expensive, would give greater strength for weight and is not subject to salt water corrosion. If this metal can be extruded in the lengths needed, and if a method can be found for upsetting the ends and attaching the tool joints, it will be a great boon to the offshore drilling industry. (5) Research on buoyancy material has received major interest from the industry and from the Navy. Static buoys are needed to support the riser casing in deep water. A syntactic foam material using glass microspheres in an epoxy matrix has been developed which appears at the present to solve the problem for static buoyancy.

The problems of stabilization of the platform, hole reentry and reduction of forces exerted on the drill string and riser casing have all received initial solutions compatible with the design limits set. The stability of the platform is such that drilling could continue in fully developed seas with winds of 30 knots and a surface current of 3 knots. A riser casing can be designed successfully to meet any specified environmental condition, but the environment is variable and the greater the variation allowed, the greater becomes the cost. The most critical points for the riser casing are at the surface where it fastens onto the platform, and at the bottom where it enters the sea floor. It has been determined that the platform cannot move horizontally from directly above the hole for a distance greater than 500 feet without endangering the riser casing. This is about 3 percent of the water depth and is an empirical number based upon the limited experience and observation gained during the phase I operation off Guadalupe Island. There is no better number available nor can one be developed without further experience. The platform's positioning system is designed to keep the platform within this boundary, and the riser casing is designed with a "bumper sub" or telescoping joint to eliminate additional tension due to the vertical movement of the platform.

Hole reentry is solved by the riser casing which, in effect, moves the hole up to the platform. If a riser casing is not to be used during preliminary drilling, a combination of a variable jet bit and TV camera is planned to guide the bit into the hole. This combination has been tried by means of an electronic computer simulation and in this way successfully demonstrated, although the real proof has to come from actual field testing. Impinging upon the hole reentry problem is the possibility of using the retractable wire-line bit. If this is successfully developed, and the chances are high that it can be, it will mean that we will not have to pull the drill string out of the hole in order to change bits, and thus we will not have to reenter the hole so often. Indications are that the bit can be designed for either turbocorer drilling or rotary drilling.

It is hoped as well that the fabrication problems of titanium drill pipe can be successfully solved.

The anticipated tensions in the drill string have been reduced by the proposed use of the improved turbocorer. With this tool it will not be necessary at extreme drilling depths to rotate the drill string

in order to drill. Since the bit is the only rotating part when the turbocorer is drilling, this eliminates high torques that would otherwise be placed on the drill string. It further eliminates the magnus effect or lifting effect that would place additional tension on the string if it were rotated at a normal drilling speed of 45 r.p.m. The string is also equipped with "bumper subs" to eliminate tension and pounding of the bit on the bottom as a result of the vertical motions of the platform. Under emergency conditions caused by storms or high seas, the riser casing and enclosed drill string are to be simply suspended by a gimbal system and allowed to swing or, more specifically, the platform is to be allowed by the gimbal to roll and pitch about the upper end of the drill string. In extreme conditions the platform would, of course, have to be disconnected.

The deepest drilling at sea to date was that successfully demonstrated in 11,700 feet of water by phase I of the Mohole project. During normal offshore exploration for oil, rigs commonly drill in water up to 300 feet in depth and work has been done at 750 feet in a few instances.

The latest estimate of the depth to pierce the mantle at the Hawaiian site is 31,800 feet which includes 14,000 feet of sea water.

When the first successful mantle drilling is completed the platform can then be used for exploratory drilling in deep water, further drilling to the mantle in other locations for comparative purposes, and for such other heavy work at sea as many develop. It is difficult to estimate a realistic completion date for the first mantle drilling because of environmental factors, and trouble that may be normally expected in drilling deep holes. However, if all goes reasonably well, that phase of the project should be completed within 2½ or 3 years after deep drilling commences, or by 1970 or 1971.

The Foundation plans to enlist the support of a user group for scientific guidance of the project. This can conceivably be arranged within the next 2 years. (At this time two advisory committees of the National Academy of Sciences are used for scientific advice.) No formal discussions as to the future have been held on this point, but there are two groups that might be interested in considering the matter. They are JOIDES (joint oceanographic institutions for deep exploration of the sea) comprised of Columbia University, the Woods Hole Oceanographic Institution, the Scripps Institution of Oceanography, and the University of Miami and GURC (Gulf Universities Research Corp.) comprised of University of Houston, Rice University, University of Texas, Florida State University, Louisiana State University, Southern Methodist University, and Texas A. & M. University. One informal meeting has been held with the JOIDES group and it was their decision that they would not be interested in taking over the Mohole project until the Mohole platform has been operationally demonstrated and when it might be otherwise appropriate. The JOIDES group desires to gain experience in drilling at sea before making any large operational commitments. The Foundation has had one informal and unofficial visit from a representative of GURC during which their possible interest in the Mohole project was expressed.

The present status of the project can be summarized as follows: The research, development, and design work is largely completed. Subcontracts for fabrication of the positioning system and some components of the drilling system have been awarded. Requests for proposals have also gone out for additional fabrication work. Some research remains to be done on drilling fluids and additives, on some parts of the riser casing buoyancy system, and some development work remains in those areas and on the instrumentation for scientific measurements to be made in the hole.

On March 10, 1965, Brown & Root issued an invitation for bid to qualified shipyards for the construction of the drilling platform. This is much the largest subcontract contemplated on the project. Bids were received from four shipyards and were opened on July 12, 1965, the apparent low bidder being National Steel & Shipbuilding Co., San Diego, Calif., with a bid of $29,967,000. During the period between the invitation for and receipt of bids Brown & Root made a detailed reestimate of costs for the entire project. Unfortunately, these estimates are very substantially higher than the earlier ones. Also because of additional time required for design and construction of the platform, the schedule has slipped by the order of a year.

With a contingency factor of $3 million added by NSF to the estimates of the prime contract, the total estimated cost of the prime contract prior to drilling is $77 million. To state it another way, the cost of putting the drilling platform in the water ready to start the preliminary drilling program is now estimated at $77 million. This is between $25 and $30 million higher than estimates of a year ago which were, of course, based on very incomplete designs and no procurement bids at all.

Drilling operations, including the preliminary work at intermediate depths, are estimated to cost approximately $11 million per year. If present estimates of time required to pierce the mantle the first time prove to be correct, the total amount expended by that time (including preliminary drilling) is presently projected to be about $110 million. Costs for NSF advisory services, including some funds for site selection studies will approximate $2.6 million and estimates for the scientific programs on core analysis and other scientific work once drilling is being done have not been fully developed.

Through fiscal 1965, $36,150,000 has been allotted to the prime contractor for the project. Our budget request for fiscal 1966 was $11 million. However, because of the increase in known and estimated costs, we are faced with reprograming the project in view of the budgetary situation.

By deferring some items into fiscal 1967, particularly fabrication work, it appears possible to award the shipyard contract before the bids expire on October 10, 1965, and keep the project essentially on schedule if $7 million in addition to the $11 million requested can be made available in fiscal 1966. An appropriation of approximately $19 million would be required in 1967 and $4 million in 1968 to complete and break in the equipment. Because of the rise in costs the project is under review. A decision on the future course of action will be made within the next few weeks.

Following is a summary of appropriated funds allocated and expended for the Mohole project to date:

Phase I, including test drilling (allocated and expended)		**$1,810,000**
Phase II:		
Funds allocated:		
Fiscal year 1962	$1,594,490	
Fiscal year 1963	3,289,100	
Fiscal year 1964	7,977,338	
Fiscal year 1965	24,699,300	
Total		37,560,228
Funds committed (expenditures often lag 12 months or more behind commitments):		
Brown & Root contract allocations		36,150,000
NSF advisory services:		
National Academy of Sciences and National Research Council	390,900	
University of California	172,600	
University of Miami	2,700	
Ocean Science & Engineering Corp	134,028	
Woods Hole Oceanographic Institute	527,000	
Messinger Consultants Co	90,000	
M. Rosenblatt & Son	73,000	
North American Aviation	20,000	
Total		1,410,228
Total funds committed		37,560,228
Expenditures and commitments under Brown & Root contract (as of June 26, 1965):		
Funds allotted to contract		36,150,000
Expended	10,693,499	
Committed	2,996,629	
Total		13,690,128
Funds uncommitted by Brown & Root		22,459,872

F-14. In 1963 a special review of Project Mohole was conducted by a committee of the National Science Board under the chairmanship of Dr. E. R. Piore. The interim report of the Committee recommended certain reorganizational changes. (a) Specifically, what changes were recommended and were these recommendations carried out? (b) Was the final Piore report ever released? (c) Could a copy of the report be furnished the Committee for the record?

The recommendations of the National Science Board Committee under the chairmanship of Dr. E. R. Piore were made to the Board at various Board meetings. The Piore committee was established by the Board to advise it concerning the Mohole project, and to assist the Foundation in resolving the various difficulties which had arisen. As their work progressed, it became apparent that the Committee could serve more effectively through Dr. Piore's participation as a Board member in the decision process than by issuance of a formal report. Although several drafts of a proposed report were circulated among the Committee members to get their comments, none was transmitted to the Board.

Dr. Piore, acting on behalf of his committee assisted the Director of the Foundation in arriving at a solution which had the backing of the National Science Board. All of the most urgent points made by Dr. Piore's committee were taken into consideration in arriving at the plan for the project now being followed. These points were:

First, that the approach to very deep drilling be done on a conservative basis, incorporating stages of "intermediate" drilling both to get experimental experience bearing on engineering design and operating techniques, and to acquire samples useful for scientific purposes. In particular, the Committee felt that we

should not attempt to design and construct a *drilling system* having initially the full depth capability for penetrating the mantle. There was at the outset a spectrum of opinion in the Committee as to whether an "intermediate" *ship* was necessary. The Committee reached general agreement on the present plan which calls for a platform equipped initially for intermediate drilling but having the size and power supply necessary to permit, with some modification, the later Mohole effort.

Second, that the Mohole project be made part of a well-planned national effort in submarine geology. It was recommended that a program of shallow drilling in the ocean sediments be initiated as soon as funds could be made available, utilizing an existing drilling vessel modified for the purpose. The effort was begun a few months ago and some shallow drilling was accomplished under the auspices of the JOIDES group of oceanographic institutions referred to earlier. The work was done by the drilling ship *Caldrill* under charter.

Third, that the NSF organization to manage the project be strengthened. Mr. Gordon G. Lill joined the staff to assume full responsibility for the program as Mohole project director. He has built up a small staff augmented by the use of private consulting groups under contract.

Fourth, that a suitable organization be selected to assume responsibility for scientific operations. This suggestion has been studied as indicated in the response to question F–10. Two such groups have been considered, JOIDES and GURC, but no understanding has been reached.

A final written report from the Piore Committee was never prepared. The final oral presentation of the committee's recommendations was made to the National Sciences Board on September 13, 1963. The report was embodied in the resolutions approved on September 14, 1963, previously summarized. This presentation was the only final report that was made.

F–15. What are the objectives of the Foundation's ocean sediment coring program costing an estimated $5 million, and the international upper mantle project costing an estimated $31 million? (a) How do they relate to each other? (b) How do they relate to Project Mohole? (c) What is the difference between the mantle and the upper mantle? (d) In effect, doesn't Project Mohole include both of these programs since it is necessary to pass through both the ocean sediment and the upper mantle in order to reach the mantle of the earth?

The objectives of the international upper mantle project are to study the outer 1,000 kilometers (approximately 600 miles) of the earth in much greater detail and in many more places than has heretofore been accomplished. Attention is being focused on the upper part of the earth's mantle because of the influence which this zone exerts in the development of the earth's crust. It is here that many earthquakes originate, here is the source of volcanoes, and from here come the forces that build mountain ranges. The mantle itself is actually about 2,000 miles thick extending from the earth's core to the base of the comparatively thin crust. It is the upper part of the mantle that is receiving greatest attention. Most of the individual projects in the upper mantle effort are land-based; only a small num-

ber are being conducted at sea. The studies include seismic, gravity, and magnetic surveys, measurements of heat flow, and laboratory studies such as magnetic properties of rocks and the behavior of rocks and minerals under high pressure and high temperature.

The ocean sediment coring program, which is a direct outgrowth of Project Mohole, has little to do with the upper mantle project, except that both are aimed at learning more about the earth. The objectives of this program are to provide information about the history of the ocean basins, their age, their structure, and the evolution of marine life. It is hoped also that a long record of the earth's climatic history will be preserved in the sediments. Cores from shallower water on the Continental Shelf will show results of large-scale transgressions and regressions of the sea, and may provide the basic data that may eventually lead to exploitation of natural resources of the shelf, including new sources of underground water off our southeast coast.

In the spring of 1961, phase I of Project Mohole demonstrated the feasability of using a drilling vessel to obtain long sediment cores. Although this was accomplished as part of the Mohole project, it was soon recognized that the way had been opened for a program of deep sea investigations that was as interesting and perhaps as important as the Mohole itself. After some discussion it was recommended that, since a sediment coring program would not (in contrast to the Mohole project) necessitate a vast engineering development program, it should be undertaken separately from the Mohole, and operated directly by interested universities or oceanographic laboratories. Another reason for separating this program from the Mohole is that most of the coring in the sediment program can be accomplished from a much smaller and cheaper vessel than will be necessary to drill the Mohole. The first months of operation of the proposed Mohole platform will certainly yield a great number of sedimentary cores from the oceanic crust, but these will be in a comparatively few locations and will complement rather than compete with the sediment coring program, which will involve many more holes over wide areas of the ocean.

Project Mohole is related to the upper mantle project only in that it is listed as one of the U.S. contributions to that project. Project Mohole had already been started by the time the upper mantle project was suggested. Since the Mohole was already organized and is monetarily larger than all of the other upper mantle activities, the Foundation and Academy agreed not to try and reorganize it as part of the upper mantle project, but instead simply list it as an ongoing project that will be a major contribution to the upper mantle project.

F–16. What agency of Government, if any, has responsibility for the coordination of Federal research and development in the three fields of air pollution, soil pollution, and water pollution? Is such coordination a proper role for the National Science Foundation?

The Secretary, U.S. Department of Health, Education, and Welfare, has the responsibility to "conduct and promote the coordination and acceleration of research, investigations, experiments, training, demonstrations, surveys, and studies relating to the causes, effects, extent, prevention and control of air pollution" (Public Law 88–206, sec. 3 (a)(1)). These responsibilities have been delegated to the Division of Air Pollution, Public Health Service. To the extent that air pollution overlaps atmospheric sciences, further coordination of Fed-

eral research and development is accomplished through the Interdepartmental Committee for Atmospheric Sciences (a Committee of the Federal Council for Science and Technology), with the U.S. Department of Health, Education, and Welfare playing the major role.

Coordination of Federal research and development on water pollution is effected through the Committee on Water Resources Research (a Committee of the Federal Council for Science and Technology). Soil pollution is included to some extent with water pollution. In addition, soil pollution is of primary concern to the U.S. Department of Agriculture and the U.S. Department of Health, Education, and Welfare. These two departments coordinate their soil pollution research and development.

Since Federal research and development in the areas of air pollution, soil pollution, and water pollution are currently coordinated, there is no need at present for the Foundation to assume such a role.

G. SUPPORT OF SCIENCE INFORMATION SERVICES

G-1. Has the National Science Foundation made an effort to discharge the Presidential 1959 assignment of coordinating responsibility for scientific information activities of the Federal Government, or has it continued to follow the statutory authority given it by the National Science Foundation Act of 1950 and the National Education Act of September 2, 1958?

The three sources cited in the question, the National Science Foundation Act of 1950, the National Defense Education Act (title IX) of 1958, and the President's directive of January 22, 1959, to the National Science Foundation, are altogether in agreement on the fact that the National Science Foundation has responsibilities to the scientific community with respect to scientific information. These sources provide, in their succession, increasing detail and increasing emphasis on the importance of this responsibility and also provide additional policy guidelines.

The 1950 act authorized and directed the NSF "to foster the interchange of scientific information among scientists in the United States and foreign countries." The 1958 National Defense Education Act established within the Foundation a Science Information Service and directed the Foundation, through such Service to "provide, or arrange for the provision of, indexing, abstracting, translating, and other services leading to a more effective dissemination of scientific information, and undertake programs to develop new or improved methods, including mechanized systems, for making scientific information available." The Presidential directive of 1959, as expressed in President Eisenhower's letter of January 22, 1959, to Dr. Alan Waterman, requested the Foundation to implement the plan that was proposed by his Science Advisory Committee. The President indicated that implementation of the plan would necessitate that the Foundation "take the leadership for the accomplishment of effective coordination of the various scientific information activities within the Federal Government." In addition, the President wrote: "I urge that the fullest use be made of existing information services, both public and private, in supplementing rather than supplanting present efforts."

The Foundation has endeavored to fulfill the responsibilities as intended and as expressed in these legislative enactments and Presidential directive, and is indeed continuing to do so. The basic authority granted in the 1950 act establishing the Foundation was given significant impetus by the National Defense Education Act of 1958, and the programs pursued since that date have been designed to give effect to its provisions. The President's directive of 1959, has provided policy guidelines. Its broader import must be understood in the light of the recommendations of the Science Advisory Committee, which the 1959 directive sought to implement. This effort did not contradict the terms of the 1950 basic authorization to the Foundation nor the

more explicit authorization provided in the National Defense Education Act of 1958. The Foundation was unable fully to achieve the effective coordination of the various scientific information activities within the Federal Government.

The Foundation enjoyed a similar responsibility, although not described in these very terms, with respect to the broader research programs carried on by agencies of the Federal Government by virtue of the 1950 act which authorized and directed the Foundation (sec. 3a–6) "to evaluate scientific research programs undertaken by agencies of the Federal Government, and to correlate the Foundation's scientific research programs with those undertaken by individuals and by public and private research groups." Reorganization Plan No. 2 of 1962, part I, section 3(a)(2) transferred from the Foundation to the Director of the Office of Science and Technology the function of evaluating scientific research programs undertaken by agencies of the Federal Government.

The need for effective coordination of science information activities within agencies of the Federal Government was the subject of continued discussion between the Foundation and the Office of Science and Technology, and also benefited by deliberation of the Committee on Scientific Information of the Federal Council for Science and Technology. In a letter dated February 13, 1964, addressed to the Director of the Office of Science and Technology, the Director of the National Science Foundation expressed the following views:

> One must recognize that each Federal agency has the responsibility of assuring that adequate scientific and technical information services are available to support its R. & D. activities. In addition, several executive departments and agencies have specialized roles in the nationwide dissemination of scientific and technical information; for example, the Department of Agriculture with information activities in support of agriculture; the Department of Health, Education, and Welfare in the field of health-related sciences; and the Department of Commerce in relation to information activities in support of industry and commerce.
>
> I agree with the recommendation of the Committee on Scientific Information that, under the intent of Reorganization Act No. 2, the Office of Science and Technology should provide leadership in effecting cooperation and coordination among Federal agencies with respect to their scientific and technical information activities. The National Science Foundation will, of course, assist the Office of Science and Technology in those areas where the Foundation has particular responsibilities.
>
> I consider one of the Foundation's primary responsibilities to be that of providing leadership in effecting cooperation and coordination among non-Federal scientific and technical information services and organizations toward the end of developing adequate systems for the collection, organization, and dissemination of information. Also, the Foundation has a major responsibility in developing adequate relationships between Federal and non-Federal scientific activities. All of the Foundation's scientific information activities, including the above, would, of course, be under the coordinating purview of the Office of Science and Technology just as are scientific and technical activities in all other executive branch agencies.

In expressing his concurrence with these views, the Director of the Office of Science and Technology replied on February 28, 1964:

> I fully concur with your views and support the concept that the National Science Foundation shall provide leadership in effecting cooperation and coordination among non-Federal scientific and technical information services and organizations, and in developing adequate relationships between Federal and non-Federal scientific activities. The Office of Science and Technology, with the assistance of the Federal Council for Science and Technology shall provide overall leadership of all Federal scientific and technical activities, including the

above, in accordance with Reorganization Act No. 2 which mentions the following responsibilities of the Office of Science and Technology: (1) major policies, plans, and programs of the various agencies; (2) assessment of selected developments and programs; (3) review, integration, and coordination of major Federal activities in science and technology, giving due consideration to the effects of such activities on non-Federal resources and institutions; and (4) assuring that good and close relations exist with the Nation's scientific and engineering communities.

The Foundation, its Office of Science Information Service, and the Office of Science and Technology have had the experience of 1½ years of activities with the relationship as agreed upon in this interchange of letters. We have witnessed significant improvement in our functions by virtue of the concentration of effort that is now permitted. We have also seen some promising undertakings which have been made possible through cooperation with the Office of Science and Technology within the spirit of this new and still developing relationship.

In short, with the exception of the requirement contained in the President's directive of 1959 for coordination of science information activities within agencies of the Federal Government, the Foundation is following the three cited sources of authority and direction. The foregoing explanation has attempted to point out that these authorizations and directives are not contradictory but rather supplement and reinforce each other. The responsibility for coordination within the Federal Government is exercised by the Office of Science and Technology: coordination with the private or nongovernmental community is recognized as a Foundation responsibility.

G-2. What steps are being taken by the Foundation to improve the techniques for the dissemination of scientific information and the understanding of the actual dynamics of the communication process?

For more than a decade, the Foundation has supported research on the communication process in science and on techniques for the dissemination of scientific information. Since early in 1964, more emphasis has been given to practical applications of research results. The following paragraphs summarize the major accomplishments and current efforts.

UNDERSTANDING OF THE COMMUNICATION PROCESS

From the studies supported by the National Science Foundation thus far, a relatively complete description of both the formal and informal processes of information exchange in one discipline, psychology, has been developed; this description has led to certain hypotheses about innovations in journals and meetings which we hope will lead to improvements in communication and which are now being tried experimentally. Useful data on communication practices and problems have also been, or are being, gathered in other disciplines: Chemists' communication activities and information sources; reading habits of chemists and physicists; search requests of physicists (analysis of them had led to improved indexing of physics journals); information exchange in the field of communications research; information sources used by engineers; communication channels used by biologists in a few selected laboratories; and the communication behavior of a large sample of industrial researchers. We hope to have within

2 years or so a more complete understanding of the communication process in several disciplines, in addition to psychology, which will help to determine how information services might best be improved.

Several studies of the interrelationships displayed by citations in scientific papers are serving to identify the "core" literature and the communication networks of the various scientific disciplines. Attention is also being given to the stimulation of new work in which other methods of studying the use of information and its impact will be employed. Thus far, studies have relied primarily on what users say they do; we hope to explore more fully the feasibility of studying communication behavior directly and its relationship to effectiveness in the performance of scientific tasks. A beginning has been made with a study of the role of information in a number of parallel research and development projects.

IMPROVED TECHNIQUES

The Foundation supports research on new approaches to the classification and indexing of information, including the feasibility of automatic classification and indexing; the results of much of this research have yet to be applied and evaluated. Several test environments have been established, within which indexing and searching techniques are being tested and evaluated. A number of basic theoretical and methodological studies are relevant to the design and evaluation of information-handling techniques and systems; particular attention is being given to methods for evaluating performance, since it is essential to be able to determine objectively whether a new technique is, in fact, an improvement over an older technique. Two new kinds of indexes, citation indexes and permuted word-in-context indexes, have been introduced with NSF support; we are now planning a program of studies to assess the utility of these and other published indexes by gathering and analyzing precise data on the search methods used with them and the results obtained. Research on automatic language processing is directed toward the possibility of automatic analysis of document content and mechanical translation. The results thus far, such as computer programs for syntactic analysis of sentences, have been used primarily in further research efforts. More work is needed before practicable application of such techniques in information services will be possible.

On behalf of the interested Federal agencies (NSF, DOD, and HEW), the National Science Foundation is monitoring a federally supported effort to adapt computer techniques to the control of information on several million chemical compounds; this effort is the first step toward a national computerized information system to serve chemists. The National Science Foundation is supporting several trials of the application of computer-controlled printing technology to the publication of scientific journals and abstracting and indexing services; and, also, a number of experiments with computer applications to library operations with a view to improving science library service in the United States.

(See also G-1; G-9.)

G-3. Does the Science Information Council's function conflict with that of the Committee on Scientific and Technical Information?

No. The Science Information Council is advisory to the National Science Foundation and its Office of Science Information Service in providing guidance on NSF's science information programs and responsibilities. The Committee on Scientific and Technical Information is a committee of the Federal Council for Science and Technology, composed of science information representatives of the several Government agencies engaged in such activities for the purpose of coordinating and improving their activities.

Although the same or similar subjects and problems will concern both groups at times, the composition, mission, relationships, and responsibilities of the two groups are different and, thus, there is no conflict between them.

G-4. What effect does the formation of the Clearinghouse for Federal Scientific and Technical Information, Department of Commerce, have on the responsibility of NSF for scientific information dissemination?

The Foundation welcomes an efficient and effective clearinghouse and continues to cooperate with the clearinghouse. The growing importance of the technical report literature generated as a result of Federal agencies' scientific research and technical development activities has created a need for access to this literature not merely on the part of Federal agencies but also by scientific and technical personnel in industry, in universities; and elsewhere. This problem was a major concern to the Office of Science Information Service until the advent of the clearinghouse which provided the basis for a coherent service responsive both to governmental and nongovernmental requirements. The Foundation also utilizes the facilities, services, and the specialized competence of the clearinghouse staff to aid in several of its own operations, as in the case of the Foundation's responsibility for coordinating the Government agencies' requirements for translations of foreign literature with the aid of excess foreign currencies, or for special bibliographic services related to reports resulting from the Foundation support of research and development in science information.

G-5. Several witnesses have alluded to the lag in statistics for policy planning for which the National Science Foundation has a focal responsibility. For example, it is noted that on July 9, 1965, the latest information available through "Federal Funds for Research, Development, and Other Scientific Activities" are estimates for fiscal year 1964 that were submitted to the Congress in January 1963.

(a) What steps are being taken to improve the timeliness of information?

(b) Is additional automatic data processing equipment required and are plans for its procurement being formulated?

I would first point out that in many instances what is interpreted as a lag in the availability of statistics results from a lack of knowledge as to what is available and from what sources and in what form. It is true that the latest data actually published in "Federal Funds" as of July 9, 1965, were those contained in volume XII. Volume XIII was published less than 3 weeks later, on July 26, 1965. Furthermore, data subsequently included in volume XIII, based on the budget submitted to the Congress in January 1964, had been published as a congressional document in September 1964. The preparation for publication of this information, relating to the geographic distribution of Federal R. & D.

funds, was a factor in the delay in publication of "Federal Funds," volume XIII. The statistical tables from volume XIII, however, were made available to interested parties during the latter part of 1964 and early 1965.

Recently, an editorial in the journal Industrial Research characterized as "helpful but outdated" an NSF report entitled "Industrial R. & D. Funds in Relation to Other Economic Variables," issued in 1964, and cited this as an example of the lack of currency of NSF R. & D. data because the report used 1958 data collected in the 1958 Censuses of Business, Manufacturers, and Mineral Industries. Unfortunately, the writer of this editorial failed to mention the statements, specifically included in the foreword and the introduction of the 1964 NSF report, that the data on other economic variables—items completely beyond the scope of NSF surveys—had become available only a few months before the Foundation's analysis was published, and that the latest year for which the Bureau of the Census has compiled these company figures was 1958. I do not wish to be thought overly defensive in this connection, but it is not unreasonable to hope that those who are interested in these matters will take into account some of the limitations under which we must at times operate.

Having noted, therefore, that we are on occasion criticized somewhat too severely, let me now say that I recognize fully that we must do more to assure prompt and timely publication of useful information.

The Foundation has taken a number of steps to provide published statistics on a more current basis, and without sacrificing accuracy, completeness, or competent analysis. It is anticipated, for example, that "Federal Funds for Research, Development, and Other Scientific Activities," volume XIV, based on the President's budget for fiscal year 1966, will be published in September or October of this year, approximately 10 months ahead of the schedule followed for volume XIII, which was published July 26, 1965. Significant improvement has also been made in publishing more current annual surveys of industrial R. & D. performance. Thus, the data from the 1964 industrial survey, for which the questionnaire was mailed to the companies in March of this year, will be published around November or December of 1965. This schedule represents an advance of 5 or 6 months over the publication time of the earlier industrial survey reports.

Improved and expanded data processing facilities will also contribute to our ability to produce and publish more timely information. A study has indicated that our present data processing equipment has become inadequate for our needs, and we have already initiated action to acquire a larger computer. The selection and procurement process is underway; delivery is anticipated in January 1966. Concurrently, our data processing staff is being enlarged to provide the necessary systems analysis and computer programing capabilities needed to assure optimum utilization of this computer for statistical analyses. The new capability being developed will still need to be augmented, as heretofore, by using outside contractors for certain tasks which (because they involve large operations or particularly urgent time factors) cannot be handled by an internal system of the size and type considered most appropriate for NSF.

(See also B-3.)

G-6. Concerning NSF collection and analysis of information about research and development—(a) What information would be desirable from Federal departments and agencies to adequately portray the regional distribution of Federal and private research and development activities? (b) How much of this information is now regularly available? (c) What has the Foundation done to advise and guide departments and agencies concerning collection of such data?

a. What information would be desirable?

It would be desirable, if the issues being posed about the geographic distribution of Federal funds are to be considered wisely, for each Federal department and agency to provide information about its obligations and actual expenditures for research and development on a State basis and on a standard metropolitan area basis. The information arrayed by these geographic units should show obligations and actual expenditures for research and for development separately; by basic and applied research separately; by fields of science for basic research; by intramural and extramural performers; by type of extramural performer—colleges and universities proper, Federal contract research centers, nonprofit research organizations, private foundations, and profit organizations; by type of academic institution classified on the basis of highest degree awarded and public or private; by location of subcontract performers, if any, down to the third tier, as well as location of prime contract or grant.

To what extent it would be feasible for Federal departments and agencies to meet these specifications for information, useful for delineating regional and other patterns of Federal funding and performance of research and development, is a question which will require separate exploration. We know from discussions of this general matter that the degree of detail here specified as being "desirable" may be obtainable only at excessive cost in terms of resources which could better be used for other purposes.

It should be noted that we are assuming in what follows that the reference in this question to "private research and development activities" refers to Federal grants to and contracts with private enterprises or organizations (both profit and noprofit), since information about research and development expenditures by private enterprises and organizations themselves cannot be provided by Federal departments and agencies.

b. How much of this information is now regularly available?

From time to time individual agencies have collected geographic data on research and development and other scientific activties on a need-to-know basis. Generally, such data are designed to cover a specific area of interest. It is anticipated that specialized requests for geographical data from individual agencies will continue to be made and that the appropriate data will be provided. For example, early this year Senator Ribicoff asked five agencies (DOD, NASA, AEC, HEW, and NSF) to provide data on obligations for research, training, and facilities by educational institutions for fiscal years 1963, 1964, and 1965. Each of the agencies submitted the requested data.

In addition, the NSF, as an auxiliary part of its "Federal Funds for Research, Development, and Other Scientific Activities" series, collected data pertaining to the geographic distribution of Federal

research and development and R. & D. plant obligations for fiscal years 1961–64. These geographic data have been published in full as a congressional document.[1] This survey represented the first full-scale effort to compile geographic Federal R. & D. data using a consistent set of definitions. It covered the eight major R. & D. supporting agencies, which account for over 98 percent of total Federal R. & D. obligations.

To accommodate some of the respondents, it was necessary to obtain the data for research and development as a combined amount. Furthermore, data were requested for prime contracts and grants only. Prior to the survey, most respondents indicated that they did not think it feasible to develop geographic data on subcontracting. The data were identified by the major categories of participating performing organizations mentioned above.[2] The Foundation is planning to collect data on the geographical distribution of Federal R. & D. obligations again next year, in its annual "Federal Funds" series.

Thus the information regularly available is substantially less detailed than that which is *a* above we have noted would be "desirable." We have been endeavoring to find ways of coping with this problem. There is no simple solution, for the statistical difficulties involved (which are in themselves great) are compounded by numerous highly intractable definitional problems.

Even so, by combining reports from performing organizations and from funding agencies (and, to a limited extent, from individuals—through the National Register of Scientific and Technical Personnel) we are gradually building up a significant body of information concerning geographical distribution of research and development funds.

c. What has the Foundation done to advise and guide departments and agencies concerning collection of such data?

As noted above, the Foundation in 1964 collected data on geographic distribution of Federal R. & D. obligations as an auxiliary part of its "Federal Funds" survey. The Foundation developed the geographic questionnaire only after meetings and agreements with the agencies. In turn, the Foundation assisted the respondents with the interpretation and application of the survey questionnaire. Where inconsistencies in reporting were evident, questions were raised as to what should be reported. The ultimate decision, however, on how the geographic distribution should be reported, was of necessity left to the discretion of the agencies, since (as the question properly notes) NSF can "advise and guide" but cannot "direct" other agencies with respect to such matters.

G–7. Since the Foundation does not require technical reports at the conclusion of a research grant, does this prevent the Science Information Service from carrying out its responsibility of leading to a more effective dissemination of scientific information?

---

[1] The complete data derived from this survey were published in September 1964 by the Subcommittee on Science, Research, and Development of the Committee on Science and Astronautics, U.S. House of Representatives, "Obligations for Research and Development, and R. & D. Plant, by Geographic Divisions and States, by Selected Federal Agencies, Fiscal Years 1961–64." This report contains more than 250 statistical tables that identify the geographical distribution of Federal research, development, and R. & D. plant obligations by the major participating performing organizations, i.e., intramural (Federal Government), educational institutions, profit organizations, other nonprofit organizations, and other performers.

[2] This means, for example, that an agency's awards to all educational institutions in a State were reported, but not on an institution-by-institution basis.

The National Science Foundation requirements for technical reports are stated as follows in booklet NSF 63–27 entitled "Grants for Scientific Research" (p. 23):

> A short informal annual report and a more comprehensive report at the termination of the grant are required. When the grant is for a period of 1 year or less, only a final report is required. It is requested that the final report contain a chronological bibliography of all publications resulting from the work aided by the grant. Four reprints of each publication should be provided as soon as such reprints become available. If adequate to serve that purpose, they may be submited in lieu of annual reports. The Foundation would appreciate being informed of any results of unusual interest whenever they occur.

The Foundation's willingness to accept publications, if adequate to serve the purpose, in lieu of reports, results from the Foundation's belief that publication of research results in the open literature, usually in scientific journals, is the best way to disseminate such results. The journals, in general, reach a wider community than do technical reports; and, in addition, the journals are covered by abstracting and indexing services, whereas technical reports often are not covered by these bibliographic services.

The encouragement of publication of research results, in lieu of technical reports issued for limited distribution, does not prevent the Science Information Service from carrying out its responsibility of leading to a more effective dissemination of scientific information, for journal publication leads to more effective dissemination than the issuance of technical reports.

G–8. How does the Foundation monitor agency responses to assure conformity to definition and to quality standards for statistics?

For its annual surveys for the "Federal Funds for Research, Development, and Other Scientific Activities" series, the Foundation provides the Federal agencies with instructions, concepts, and definitions, and assists them with the interpretation and application of the survey questionnaire. New questions are introduced in the surveys only after meetings and agreement with the agencies. Meetings are held with the major agencies prior to initiation of each annual survey. Liaison is continued with the major agencies throughout the year. In addition, the major agencies are provided the data they reported in the preceding report and these "shuttle" data are used to encourage comparability of reporting from year to year.

The Foundation evaluates the responses when they are received and raises questions when inconsistencies in reporting are evident. The ultimate decision, however, on how activities will be classified and the amounts to be reported is left to the discretion of the agencies.

When, for conceptual reasons, an agency revises the classification of its R. & D. operations and the resulting allocation of funds, it is asked to revise its previous reports in order to establish consistency and comparability with the current report.

It should be recognized that no statistical inquiry is free from problems for the respondents arising from the application of definitions. Classification is particularly troublesome for the respondents because scientific activities are abstract and far from immutable, and they resist easy summarization into dollar and manpower terms. An element of subjective "best judgment" often enters when an agency classifies its operating programs and identifies funds for basic research, applied research, or development. Admittedly, there are often no

clear-cut demarcations between these work categories. The same element of subjective best judgment also often exists in classifying large interdisciplinary undertakings by primary fields of science. Since only the most important criteria can be encompassed by a definition—without an encyclopedic enumeration of all relevant criteria—assurance that the agencies conform to the definitions can be attained only in a relative sense.

G-9. Are there enough funds available for carrying out experiments to apply new knowledge, techniques, and equipment for more efficient information retrieval systems?

The funds available in the immediate past years have been reasonably sufficient to support experimental applications of new knowledge, techniques, and equipment to information systems. This has necessitated, however, careful screening and support of a limited number of such activities. We presently foresee an increasing pressure for exploitation and application of newly developed capabilities. This pressure will be amplified if the present thrust toward development of national information systems is followed through. A 2-year experimental effort to determine the feasibility of a national chemical information system required cooperation by three agencies to provide the $4.2 million entailed in this effort. If anticipated efforts by organizations serving the communities of physicists, engineers, and other disciplines materialize, the present funding level will be far from sufficient to satisfy the implied requirements.

(See also G-2.)

G-10. The fiscal year 1966 budget request contains $9.5 million for university computing facilities, including replacement of computers provided in the late 1950's. (a) Does the National Science Foundation let grants for renting computers as well as buying them? (b) Would it be more economical for the Foundation to have rented the computers which it is now replacing?

(*a*) Yes.

(*b*) In our opinion, no. In judging the merits of a proposal for assistance to an institution planning to rent or purchase a computer, the Foundation gives particular consideration to the soundness of the institution's financial plans and to its justification for the choice between renting or purchasing its equipment. We have found no reason to impose a uniform policy favoring either of these options, since in each individual case a number of factors must be considered. Among such factors are the institution's financial resources including limitations such as those that might be imposed by the State legislature, its administrative structure, any special circumstances involved with the computer manufacturer, as well as the expansion of the use of the computer in the institution's research and educational activity. In many cases, also, the institution's judgment as to the probable useful life of the equipment differs from that of the Government auditors who often insist on depreciation over much longer periods. Typically, purchase prices set by computer manufacturers are between 45 and 50 times the equivalent monthly rental; understandably the imposition of a substantially longer base for depreciation can affect the institution's choice. In all cases, the Foundation's contribution has amounted to substantially less than the full cost of buying or renting the equipment.

The wording of the question suggests that the Foundation itself rents or purchases computing equipment for university use, questioning whether, under such circumstances, it would have been more economical to have rented this equipment in all cases. As indicated above, this has not been the manner in which this program has operated. We estimate (NAS–NRC report "Digital Computer Needs in Universities and Colleges," in draft) that there is today an investment of $9 million in equivalent monthly rental at colleges and universities, of which about 50 percent is being supplied through manufacturers' discounts. By 1969 this investment will have increased to more than $18 million of which less than 35 percent will be offset by manufacturers' discounts. This generous discount policy to educational institutions on the part of computer manufacturers in itself more than offsets the economies which could be derived through consolidated purchase or rental options available to this agency.

H. Scientific Manpower Problems

H-1. You testified that, in general, there is not enough financial support to go around for all the good men available. (a) What level of support is needed? (b) How much more support is needed overall than at present? (c) What are the basic problems in meeting our national goals on manpower?

During the past several years the Foundation has been able to make grants in support of only slightly more than half of the research proposals on which it acts, despite the fact that 80 to 90 percent of the proposals are adjudged to have sufficient merit to warrant some support were the funds available. On an annual-rate basis the average amount granted for those proposals which are supported is of the order of two-thirds of the amount requested. On a weighted basis the average proposal requests a duration of about 2.5 years whereas the average grant given is for about 1.6 years. Reductions in annual rate are accomplished by reducing the amount of equipment and the number of personnel for which support is provided. It may be roughly estimated that if all proposals which are now supported by the Foundation received support at an optimum level rather than a stringent one as at present, an increase in available funds by about 20 percent would be required, assuming no increase in duration. If, in addition, those worthwhile proposals are to be supported which are now being declined, but which would receive support if funds were available, an additional increase by about 50 percent would be required. In summary, an overall increase by a factor of about 80 percent would be required to adequately take care of all the worthy projects proposed to the Foundation. The basic research project support budget for fiscal year 1966 is estimated at $155 million. The amount required to provide reasonable support for all good proposals would be closer to $280 million. We are unable to determine on a meaningful basis the number of able scientists and engineers who—in part because they know that competition for available funds is so keen—do not submit proposals. We know of enough such cases, however, that it seems quite reasonable to assume that they constitute a considerable number—perhaps as much as half of those who do submit. However, it seems safe to assume that the larger group and somewhat more expensive efforts are well represented in the requests received, so that the additional proposals we might receive under more affluent circumstances would not, on the average, be for as large amounts as is the case at present.

A basic problem in meeting the Nation's manpower goals lies in defining the manpower needs. No one has solved this problem fully. It is difficult, in a system as complex and dynamic as is the U.S. economy, to determine the supply of and demand for individuals of given types of skill or preparation on a current basis. It is not possible to determine what the demand (and, to a lesser extent, supply)

will be a number of years hence. To do the latter would require a fairly detailed knowledge of scientific discovery and technological developments as yet unknown, the State and nature of the national and world economy and social development, and the employment aspirations of individuals.

Further, while it is perfectly possible to educate and train individuals to perform specific duties, that way leads quickly to manpower obsolescence. In the Foundation's view the most rational approach to the problem of scientific and technological manpower is to provide educational opportunities for a comparatively large pool of individuals, and encourage an educational approach that leads to breadth of knowledge rather than narrow skills. This approach leads to highly flexible manpower supply, the only meaningful kind for an unpredictable future. We must not lose sight of the implications of the fact that, of our leading nuclear physicists, only a scant few were originally so trained: the same is true in oceanography, biophysics, computers, molecular genetics and most of the other fields of science now most active.

H-2. Are further studies needed to make long-range plans of Federal agencies more reliable in forecasting future requirements for scientific and technical manpower? If so, of what nature?

Yes, further studies of this type are clearly needed, but it should be recognized that the problem on which they will focus bristles with difficulties, whether it is that of forecasting the requirements for scientific and technical manpower of the Federal Government or of the Nation as a whole. (I mention these alternatives because it is not clear whether the question has in mind the first, second, or both.)

Better—in the sense of more accurate and reliable—forecasts of manpower requirements than are now available will, I believe, depend upon studies of a quite fundamental nature which (*a*) improve the information available on the quantitative and qualitative characteristics of existing stocks of scientific and technical manpower and of existing employment patterns within the public and private sectors; (*b*) illuminate understanding of the factors affecting demand and supply; (*c*) identify the sources of error implicit in techniques used up to now and revealed by the shortcomings of their results; (*d*) provide better clues to impending and more remote changes in the direction, content, and purposes of public policies; (*e*) investigate in detail the experiences and behavior of governmental employers in the labor market; (*f*) center on problems of utilization, mobility, substitutability, obsolescence, and retraining of scientific and technical manpower; (*g*) determine the feasibility of developing techniques for forecasting technological innovations and changes; and (*h*) seek to determine the consequences for national policies of alternative assumptions with respect to different requirement levels, conceived both as expressions of social "needs" and of effective demand.

Still other types of studies would also contribute to more reliable forecasts. This has been made clear as a result of the attention paid to this subject by the NSF, the Department of Labor, the President's Committee on Manpower, and others. Those studies which I have mentioned in shorthand fashion should not, therefore, be viewed as constituting an exhaustive list. It is perhaps worth adding that my impression is that among experts in this field there is currently no

high optimism that striking advances in forecasting techniques and results should be expected to be made in the immediate future.

H-3. What does the Foundation consider its responsibility to be in the area of retraining? Does it feel this element of manpower utilization and refreshment as important as the development of new manpower?

Because of current needs for qualified scientists and teachers of science, the Foundation feels that its retraining activities are as important as the development of new manpower. The retraining activities supported by the National Science Foundation serve all segments of the scientific community. These activities provide opportunities for the retraining of out-of-date teachers of science and the updating of scientists engaged in research, principally (but by no means exclusively) in universities.

Retraining of scientists and engineers employed in for-profit (industrial) organizations is important, but this problem is one which the Foundation has approached cautiously, insofar as specific programs directed toward this group is concerned. The retraining of teachers is directly related to the Foundation's responsibility; the relationship of the industrial scientist or engineer to our assigned functions is less clear. The Foundation's limited activity in assisting non-university scientists is directed principally at the encouragement of effective "self-help" projects for individuals. The Foundation is, of course, concerned that appropriate opportunities for "refresher" training at universities be available to all those who can, by virtue of such training, make more effective contributions to science and technology. Thus, although the Foundation's major effort in the area of retraining has been centered on teachers and researchers closely associated with the educational establishment, several of our programs explicitly make provision for participation by Government and industrial scientists.

Perhaps best known among its varied "retraining" activities is the Foundation's large program of institutes and conferences offering group-training for teachers of science, mathematics, or engineering at the various educational levels. In fiscal year 1965 alone the estimated number of teachers who received support for institute participation totaled 41,910 (4,082 college teachers, 34,397 secondary school teachers, 3,431 elementary school personnel). The number of teachers in our schools and colleges who are teaching science, mathematics, or engineering is enormous. Not only is retraining required for those who were inadequately prepared initially, but updating of scientific knowledge for all teachers in the sciences becomes necessary as scientific knowledge expands and advances. To date, NSF-supported academic year institutes, summer institutes, inservice institutes, and conferences have made significant progress in helping teachers improve the quality of their science instruction. There is, of course, much more that remains to be done in this area.

In the interest of helping to alleviate the national shortage of science and mathematics teachers—which increases as student enrollments expand—the National Science Foundation has been exploring new sources of potential teachers and experimenting with retraining programs specially designed for the needs of this group. These experimental efforts which have been supported on a limited scale since 1957,

are especially the responsibility of NSF since they provide novel approaches to the problems of manpower for science education.

Retraining and initial training are not competitive, but complementary activities. Their interrelationship is so great that it is difficult to assign relative importance. For a short range need, support of refresher training for those who already had some experience in the sciences and teaching appears to be logical. For a long range requirement, it might be preferable to provide first-rate instruction to college students whose primary interests were in science and mathematics teaching and to encourage them to make a long-term, successful career of teaching. It is true that in time these new teachers will become outdated, but the point is that with good initial training, the only supplementary training required will be that of updating, without the additional burden of removing original inadequacies.

The Foundation has always, in its science education activities, stressed the importance of quality. This has meant (and still means) that NSF efforts have been directed toward assuring the maintenance and strengthening of strong educational programs of high quality wherever science is taught—no matter who the students may be. We have supported extensive efforts to find better programs of study in several fields (engineering, for example), and to the extent that these efforts are successful they will be as applicable to those preparing for (or now working in) industrial jobs as for those employed in other sectors of the economy.

The matter of the relative importance of "initial" and "refresher" training cannot be answered simply, because there are so many factors to be considered under a given set of circumstances. As our program activities show, we currently assign high priority both to initial training and to retraining programs.

H-4. What studies, if any, is NSF sponsoring to provide more information on the nature and rate of obsolescence for scientific and engineering personnel, and about effective countermeasures? Are we ignoring or wasting the technical manpower resource of older scientists whose early academic training has been superseded by new methods?

The problems involved in defining and assessing obsolescence in scientific and engineering personnel are manifold. Though we cannot predict the extent and timing of obsolescence in an individual as one might in a machine, we must assume that obsolescence, however the term is defined, will take place. An exploratory study has been completed under our auspices, the object of which was to determine the potential usefulness of evaluating representative formal and informal types of continuing education in offsetting the obsolescence of technical skills of scientists and engineers. The Foundation is now in the process of conducting discussions with prospective contractors, to further refine the issues and design, preparatory to launching a full-fledged study. In addition, the study of the impact of R. & D. instrumentation on scientific and technical manpower recently undertaken by the Battelle Memorial Institute with the support of the Foundation will concern itself in part with the extent to which increasing dependence on advance instrumentation systems for the performance of R. & D. increases the obsolescence of the skills and technical competence of professionally trained scientists, engineers, and technicians.

Specific countermeasures have been developed and, in our opinion, pursued with some success in areas such as:

(*a*) Studies of both undergraduate and graduate curriculums by national groups, such as the Commission on College Physics and the Committee on the Undergraduate Program in Mathematics, in specific areas of science and engineering with the subsequent publishing of recommendations or "guidelines." These guidelines are in important countermeasure against obsolescence in that they make specific recommendations for curriculum construction to be used by colleges and universities in remodeling their old programs for training scientific and technical personnel or establishing new programs. Two characteristics of the work of these groups are worthy of note here: the recommendations are based on (1) a philosophy which will result in a training program general enough to insure maximum adaptability in the individual as well as specific enough to insure competence "on the job" initially, and (2) a thorough consideration of the future of the particular field to insure optimum utilization of up-to-date subject matter in the form of revised courses and innovations in learning experiences.

(*b*) Studies of the content of specific science courses and the development of model courses which (1) in addition to being representative of the most modern subject matter content also offer methods of presentation of the material which are responsive to present day theories of learning and knowledge of human behavior and (2) are designed to foster in the student habits of independence of thought and an ability to learn from one's own inquiry. These factors are, in our opinion, of upmost importance in combating intellectual obsolescence in any field.

(*c*) Support of programs designed to retrain and update personnel in all segments of the scientific community through individual or group study lasting as long as an academic year or more or an advanced level seminar lasting for only a few days. These programs retrain out-of-date teachers of science at all levels and update scientists engaged in research in universities as well as scientists in industry and government.

The NSF is not ignoring the older scientist whose early training has been superseded by new knowledge and methods. A recent study of the records of some 18,500 individuals applying to NSF-supported retraining programs and the approximately 6,500 individuals who actually participated shows a clear trend toward selection of the older scientist. Using age data from the National Register of Scientific and Technical Personnel, the typical scientist is about 38 years of age. The typical scientist participant in NSF-supported retraining programs (institutes, conferences, and research participation programs) during the last 2 years is about 40 years of age. In addition, a comparison of the age distribution of applicants to these programs and the age distribution of participants shows a clear trend toward the selection of the older individuals from among those applying. In each 5-year age category above age 40 (except age 66 and over) the percent of total participants is greater than the percent of total applicants in that same category.

H-5. What is known about the size and makeup of that part of the population which has the basic capacity to become scientists or engineers? Does this set the ceiling on their production? Could more graduate students be supported without compromising quality, or has this limit already been exceeded?

If one uses as a criterion for "basic capacity" an IQ (Army standard scale) score of 110 or better, in a distribution of the general population, approximately 30 percent of each age cohort possesses the requisite capacity. Among 1965–66 high school graduates, this will be approximately 1,266,500 boys and girls, 622,000 being boys. However, capacity is not the only factor. The limit upon producing scientists and engineers is also greatly influenced by difficulties at the high school and college level resulting from inadequate preparation, by motivation (a problem associated with sex, parental occupation and education, ethnic and religious background, and other sociocultural factors), by income (the problem of support for students), and by other pressing responsibilities induced by society (such as marriage responsibilities and military duty). General capacity may be subdivided into a number of more elementary aptitudes. A major national study designated as Project Talent developed, on a judgmental basis, four measures (general academic aptitude, quantitative aptitude, technical aptitude, and scientific aptitude), and identified 17.4 percent of high school graduates as having "exceptional scientific aptitudes" using as a measure those scoring in the 90th percentile on at least one of these tests.

Using this more limiting criterion, there will be as many as 441,000 high school graduates in 1965–66 having "exceptional scientific aptitudes." Project Talent test results showed that boys scored better in these aptitudes than girls. The respective estimates for the 1965-66 graduates are 362,000 boys and 79,000 girls who will possess exceptional scientific aptitudes.

Not all of these will enter college, however. It is variously estimated that two-thirds to three-quarters of boys from the top third of their high school graduating class and one-half to two-thirds of the girls from the top third of the class enter college the following fall. Dropout from college further depletes the number, generally estimated at 40 percent dropout of all entrants. Studies suggest that about one-third drop out because of poor academic performance and one-third because of finances.

Among those receiving the baccalaureate, approximately one-third have academic records of B or better (excluding those with an average of B— or less), and about three-fifths have records of B— or better. While some college graduates with poorer records attend graduate school and receive master's and even doctor's degrees, let us consider those with undergraduate records of B— or better as qualified.

Upon this basis, and using the results of several surveys, the following estimates were made of the percent of capable baccalaureate recipients who are not enrolled for graduate study the following fall and

what this means in terms of numbers of 1965–66 bachelor's degree recipients who will probably not enroll for graduate study in 1966–67.

	Percent of capable baccalaureates not enrolled for graduate study following fall	Estimated number of 1965–66 class who will not enroll 1966–67
Physical sciences	38	11,500
Engineering	29	4,800
Life sciences	46	9,200
Psychology	32	2,300
Social sciences	66	12,000

The high percentage for the social sciences is due to the larger proportion of females who receive baccalaureate degrees in these fields. As time passes more graduates undoubtedly will enter advanced training. It is clear that additional capable baccalaureates could be supported in graduate study.

In summary, approximately 30 percent of each age group is capable of being trained in the sciences. The limitation on developing scientists is not only native capacity but high school and college graduation, which, in turn, rests upon prior preparation, motivation, income, and the presence of other demanding responsibilities.

There still are capable baccalaureates in science fields, perhaps approximately one-third of the capable graduates, who are not immediately entering graduate study. The "interface" between high school and college and the various "weeding out points" between college entrance and college graduation, however, are much more important sources of loss of potential scientific talent than between college graduation and entrance into graduate study.

If the United States is successful in achieving its goal of equal educational opportunity for all, we will have many more well-qualified students available as potential candidates for advanced degrees in science and engineering—as well as in all other fields.

II–6. What is the explanation for the NSF report in which a shortage of scientists and engineers was projected under the next 10 years, in contrast to the Killian report released about the same time that cited no across-the-board shortage?

The NSF report in question is "Scientists, Engineers, and technicians in the 1960's (NSF 63–34) which was prepared by the U.S. Department of Labor in 1962 with financial support by the Foundation. The report appraised the growth of scientific and technical occupations and concluded, under the assumption of growth rates continuing through the 1960's at the same approximate rates as during the late 1950's, that the college output of new bachelor degree scientists and engineers would be insufficient to meet needs by 1970. The report pointed out that such trends might change, however, and that such projections themselves might be influential in changing demand-supply relationships.

The report of the Committee on Utilization of Science and Engineering Manpower entitled "Toward Better Utilization of Scientific and Engineering Talent—A program for Action" (better known as the Killian report) was issued in 1964, at a time when readjustments in the defense and space programs had resulted in contract cancellations and even release of some engineers by industry. The report concluded that:

> At present, there are both unfilled positions and unemployed scientists and engineers. Conditions vary by region and specialty. There are unmistakable shortages of manpower in the advance technologies of new engineering systems, of scientists and engineers with technical and administrative skills required for the effective management of large scientific and technological undertakings, of teachers of science and engineering, and all persons with doctorates in mathematics.
>
> Also at the present time, there are identifiable surpluses resulting, for example, from industries changing from older to new technologies * * *. Currently, changes in the programs of the Department of Defense are resulting in cutbacks in certain types of employment. A number of engineers face problems of adapting themselves to more advanced technologies as the older skills become obsolete. Thus, the employment situation remains mixed.

Any comparison of the findings of these two reports should note that one represents a projection of trends of the late 1950's to 1970 under clearly stated assumptions. The other report speaks to the situation found in 1964, a year of Government contract readjustments. The NSF report made no appraisal of the situation in 1964, and it is possible that if it had done so, its conclusions for that year might not have been far different from those of the Killian report. This is to say that a situation projected for 1970 will not necessarily be reflected to the same degree in each prior year.

As hazardous as projections can be in any area as uncertain as occupational requirements, our information indicates continuing strong needs for engineers trained in the new technologies, for well-trained scientists with graduate degrees, and for new science faculty members to meet the rapidly growing requirements of colleges and universities. Recruitment of engineers on college campuses during the past spring was reported at record levels. It should perhaps be emphasized that a gap between the industrial needs for engineers and the number of new graduate engineers in 1970 will not necessarily be evidenced by a corresponding number of unfilled jobs. The situation will more likely be an adjustment in job requirements which will permit the utilization of nongraduates with less adequate training.

H-7. With the advent of the space age the charge has been made that rapid development of space technology has drawn many of the best professors, practicing engineers and students away from aeronautical engineering into the more intriguing and glamorous field of space engineering, research, and development. Is this true? And if so, is it cause for concern? Is any program in existence or contemplated to assure a balanced input of graduate space scientists and aeronautical engineers into the scientific and technological communities?

There is no doubt that the expansion of the space program of the Federal Government, first in fiscal year 1959 and again at a higher level in fiscal year 1962, created increased requirements for scientific and technical personnel throughout the economy. However, these requirements for personnel were not in direct proportion to expendi-

tures, because of the higher cost per technical man in these programs. Furthermore, the expansion in the early years of the program was offset somewhat by decreases in expenditures made by the Department of Defense for research and development programs. In summary though, the increases in the space program together with the growth in other Federal programs and the general expansion in the economy have resulted in greatly increased needs for scientific and technical personnel.

In answer to the more specific aspects of the question; namely whether the *best* personnel have been drawn away from *aeronautical* engineering to space work, very little is known about the movement of professors and practicing engineers. On the supply side, degrees granted in aeronautical engineering have in general kept pace with trends in other engineering fields; at the graduate level aeronautical engineering has kept ahead of most other branches.

We have tried (but without great success) to find ways of characterizing movements of personnel on the basis of quality. At present there are no generally acceptable quantitative measures to determine the ability of scientific and technical personnel, which can be used to identify the "best" persons. Furthermore, the factors affecting career and even specific employment choices relate to immediate financial gains (including prospects of support as students), long-run career opportunities, opportunities for stimulating work and professional advancement, and even geographical considerations.

There is no overall plan at the national level, either in the Federal Government or elsewhere, to provide for a "balanced" input of trained personnel into specific programs. Activities in the Government and other sectors of the economy are determined on their own merits and in the case of most programs decisions are made on a decentralized basis to advance individual missions and goals. However, the Federal Government, through the Office of Science and Technology, the various individual agencies, and the Congress is continually reviewing various programs to detect gaps and to stimulate activities where such motivation is indicated.

(See also E-13.)

I. Supplemental Questions

I-1. Assuming that NSF budget and responsibility accelerates to the extent that our hearings suggest, this would seem to require that you preserve and increase the scientific standing and competence of your senior staff. Will not this require (1) an increase in senior staff, and (2) additional delegation of authority in the manner in which Cabinet members now delegate authority to Assistant Secretaries, etc.?

I-1. Whether or not NSF budgetary and programmatic responsibilities increase at a rate faster than they have heretofore, we must of course agree with the idea that substantial increases in the size and in the "scientific standing and competence of [NSF] senior staff" will be required in the years immediately ahead. It has been my aim since I became Director of the Foundation to avoid unnecessary increases of personnel. Through various reassignments of responsibility and through the elimination of certain staff elements which were deemed no longer essential, it has for some 2 years been possible for us to absorb an increasing workload with very little increase in staff size. However, it is clear that the work we now face, in attempting to accomplish the tasks I have earlier outlined for the subcommittee, will require a larger staff. In particular, we will have to recruit a number of individuals at a fairly senior level; this will clearly entail corresponding increases of support personnel at lower levels.

As I testified on August 19, it is my intention to carry forward soon plans for additional delegations of authority which have been materializing for some time. When Reorganization Plan No. 5 was allowed by the Congress to come into effect on July 27, 1965, certain ambiguities were removed as to my freedom to delegate to others those actions which had been placed within my purview by specific resolutions of the National Science Board. Thus it is my intention to assign both responsibility and authority to associate directors for dealing with certain grants below a specified size. Already the associate directors are primarily responsible for a wide range of matters relative to the recruitment and training of full-time employees; the securing of consultative services; liaison with coordinate groups in other agencies of Government and with appropriate nongovernmental bodies; approval of studies to be carried out by NSF or by contractors; determination of the need for and duration of travel on the part of staff members; and a number of comparable matters. (Obviously, all those concerned recognize that special cases which arise—even within relatively clear-cut assignments such as these—are to be brought to the attention of my deputy or myself.)

No one can appreciate more fully than I do the desirability—indeed, the necessity—of moving as far and as rapidly as possible to delegate to the appropriate organizational level all elements of authority that can, with propriety and within the broad constraints of good management, be assigned to others.

I–2. Section 3a(2) of the National Science Foundation Act directs the Foundation "to appraise the impact of research upon industrial development and upon the general welfare." What has NSF done and what is it doing to carry out this directive?

I–2. In carrying out the functions described in section 3a(2) of the National Science Foundation Act, the Foundation has borne in mind the great breadth of this provision of the act and the need to stimulate scholarly inquiry into this subject throughout the country. It has obviously been necessary to be selective in exploring various aspects of the effect of research upon the general welfare and, more particularly, upon industrial development.

Activities have, accordingly, been organized which balance continuing intensive effort in some areas with exploratory projects in a number of other directions where inquiry by other interested groups can be stimulated. These activities comprise surveys of research and development, special economic studies, and conferences on research and development.

The various surveys and studies of research and development expenditures and manpower all provide a statistical background for measuring the "impact of research upon industrial development and the general welfare." The Foundation has a regular series of studies and surveys designed to make available information on the deployment and utilization of scientists and engineers in industry and the other sectors of the economy. In addition, the Foundation has sponsored studies by the National Bureau of Economic Research, the Engineers Joint Council, and the Bureau of Labor Statistics to appraise the manpower supply in relation to anticipated requirements with particular emphasis on research and development scientists and engineers. The National Register of Scientific and Technical Personnel has made possible numerous studies relating to the characteristics of scientists and engineers, including their training, work activities, type of employer, income, and mobility.

A continuing study of particular significance is the annual survey of industrial research and development which was first sponsored by the National Science Foundation in 1953. This survey[1] has been conducted annually since that time, except for 1954 and 1955. The questions, definitions, and instructions in the survey have been developed by the National Science Foundation in consultation with Government, university, and industry officials. The individual questions are designed so as to pick up information on changing patterns of industrial research. The survey provides the following R. & D. data by industry and size of company on a regular basis:

(1) Funds for basic research, applied research, and development;

(2) Sources of industrial expenditures (Government and industries' own funds);

(3) Product areas of research; and

(4) Fields of basic research.

Additional data are provided on research contracted to outside organizations, such as other companies, commercial laboratories and consultants, educational institutions, nonprofit research institutes and

[1] The Foundation provides the financial support for the data collection, but the Census Bureau carries out the survey.

foundations financed by industrial firms; research and development by major type of expense; and number of R. & D. scientists and engineers.

New inquiries have been added to the survey questionnaire from time to time for the purpose of developing special data required for Government policy planning. Recent examples of such questions are (*a*) R. & D. expenditures by State and geographical division, and (*b*) the number of R. & G. scientists and engineers and the associated R. & D. costs for personnel working in industry on NASA and DOD contracts.

Thus, the annual industrial survey is rich in providing background information on the "impact of research" because of the close relationship between industrial research (particularly company financed) and technological change that arises through the introduction of new products and processes. The data from the industrial survey together with those from other surveys sponsored and conducted by the National Science Foundation, find frequent use in both the legislative and executive branches of the Government as well as in industry itself.

While the annual industrial survey provides a framework for appraising the changing patterns of industrial R. & D. activities, special studies have been designed to probe deeper into special problem areas of research and development.

Many of these studies were instrumental in suggesting new areas for further research and analysis by other investigators. An indication of the growth of interest in this type of research may be gleaned from the NSF publication "Current Projects on Economic and Social Implications of Science and Technology." In 1959, this publication listed 96 studies being conducted at universities and colleges related directly or indirectly to the "impact of research." In the most recent edition of the publication—1964 (in print)—the number of studies listed was 405.

"Role of Research and Development and Technological Change (Innovation)": A series of studies, conducted under contract and resulting in the publication of three reports ("Reviews of Data on Research & Development," No. 31 (NSF 61–52), No. 34 (NSF 62–16), and No. 38 (NSF 63–12)), examined the relation between a firm's output of important innovations and the size of its R. & D. expenditures, interfirm diffusion of technological change, and differences in the adoption of innovations by firms within selected industries.

"Decision Making on Research and Development in Industrial Firms": This study, also conducted under contract, provided information on the factors affecting R. & D. spending in industrial firms, firm behavior with regard to decisionmaking, R. & D. budget allocation, and project selection processes. The findings of the study were published in Reviews of Data on Research and Development, No. 44 (NSF 64–6).

"Allocation of R. & D. Resources Within a Company": The contractor of this study, by using operations research techniques, made a pioneer case study for the purpose of providing guidelines for the difficult problem of optimum allocation of research and development resources within a company. The findings of the study were published in the December 1962 issue of IRE Transactions on Engineering Management.

"Special Reports on Individual Industries": The National Science Foundation has prepared and published analytical reports on three individual industries—aircraft and missiles, chemicals and allied products, and electrical equipment and communication—each of which accounts for a relatively large share of the dollar volume of total industrial R. & D. performance. These reports, published in the series "Reviews of Data on Research and Development" (No. 39, NSF 63–19 and No. 42, NSF 63–41), and in "Reviews of Data on Science Resources," (No. 3, NSF 65–3), provide background information on research orientation in the particular industry as well as an analysis of various R. & D. data related to that industry.

"Special Report on Research and Development and the Gross National Product": The National Science Foundation prepared a report comparing R. & D. expenditures to the national accounts including both private product and Government product to provide a basis for viewing the level of R. & D. expenditures in relation to the Nation's total annual economic expenditures. This report was published in "Reviews of Data on Research and Development," (No. 26, NSF 61–9).

"Relationship of Statistics on Research and Development to Other Economic Variables": The results of a special study of what is planned to be a sequence of studies was published recently in the Foundation's report "Industrial R. & D. Funds in Relation to Other Economic Variables." This study compared and analyzed data on research and development with several other economic variables, such as employment, payrolls, sales, value added by manufacture, and new capital expenditures in both companies with R. & D. programs and companies not reporting R. & D. programs. A second phase of this study will be undertaken in the near future as data from the 1963 Census of Business, Manufactures, and Mineral Industries become available. Availability of these data will make it possible to extend the number of statistical relationships in terms of time series presentation.

"Analysis of Regional Patterns of Research and Development and Science-Based Technology": A study conducted under contract is currently investigating the regional patterns of research and development and science-based technology. The study will provide a detailed analysis of existing care studies of the effects of R. & D. concentration in local areas and interactions with research-based industry; initiate and complete intensive case studies of three other areas (Santa Clara County, Calif., the urbanized area of the northern part of Utah and Winston-Salem, N.C.); and assess the local impact of research and development and research-based activity, as reflected by the case studies.

"Research and Development in Smaller Manufacturing Firms": Completion of this study in the near future is expected to yield valuable information and data about the factors which limit participation of small firms in R. & D. activities. The annual NSF surveys of industrial research and development clearly demonstrate that small firms, as a group, perform less research and development relative to the size of their operations than do larger firms. The study will also examine various approaches to stimulate research and development in small firms and enhance their growth potentialities.

In addition to the studies described above, which have either been completed or are in process, the National Science Foundation is planning to undertake in the near future several other special studies of a comparable nature. Thus there has, since 1953, been compiled a growing amount of information on the nature of the U.S. commitment to research and development and the relation of that commitment to industrial development and the general welfare. A broad basis for understanding these relationships has been developed, but much more needs to be done to provide the specific details which will enable effective planning to meet future needs in a rapidly changing technology.

I-3. Would there not be an advantage, from the standpoint of too much inbreeding of the Government-science relationship, if members of the National Science Board did not serve simultaneously on the President's Science Advisory Committee?

I-3. In my opinion, the simultaneous service of a few members of the National Science Board on the President's Science Advisory Committee constitutes an advantage to the National Science Foundation. The National Science Board has 24 members from outside the Government and the number of these members who also can serve concurrently on the President's Science Advisory Committee is of necessity extremely limited. There is no problem, therefore, of the possible imposition of the views of the President's Science Advisory Committee upon the Science Board. Rather, such membership on both bodies affords an opportunity for close liaison and heightened interchange of information and ideas. The particular experience and broad knowledge gained by service on the President's Science Advisory Committee by a few Board members adds an extremely valuable input into the deliberations of the Board. Personally, therefore, I believe such simultaneous membership—so long as the overlap in membership is small, as it always has been—serves a very useful purpose and enhances the effectiveness of the National Science Board without in any way affecting its independence.

I-4. You have indicated ways in which the Foundation is able to check the quality of research projects and of educational grants and fellowships. However, how does the Foundation check on the quality of its summer institutes? Is there any specific mechanism set up for this purpose?

I-5. What evidence do you have that the majority of the summer institute programs for teachers is effective?

I-4. The Foundation has devoted a great deal of attention to—and has spent substantial sums on—the evaluation of the quality and effectiveness of its summer institutes. No other activity of NSF has had as much effort devoted to its continuous assessment. Several specific mechanisms—some continuous and some ad hoc—have been set up for this purpose.

A regular cycle of site visits to institutes while they are in operation is carried on annually, employing members of the staff plus about 45 consultant scientists. An attempt is made to visit all new institutes and to visit continuing institutes every second or third year. During the summer of 1965, 331 of the 616 summer institutes received a visitor. Typically the visitor spends about 2 days at an institute, and not only checks on its quality and on the reactions of the participating teachers, but provides helpful guidance and counsel so as to help improve the

quality of the institute through application of ideas which have proved useful in other institutes.

That the vast majority of the summer institutes are effective is clear in the reports of these visitors. Through their contacts with faculty members and with groups of participants they report accomplishments in the increase of the teachers' knowledge of subject matter, and their appreciation of its potential application in improvement of their teaching of science. Seldom is a report received of any institute which is not judged effective, although their effectiveness does differ in degree.

No precise measure of the impact and efficacy of a specific institute can be provided, because of the difficulties of establishing a norm for comparison and of separating the effect of institutes from the concurrent effects of course content revision, of the general post-Sputnik increase in interest in science, and of the changing teacher population. However, much evidence of specific effects is available to back up the statement of Dr. James B. Conant in his 1963 book, "The Education of American Teachers."

I–5. The use of NSF summer institutes for bringing teachers up to date in a subject-matter field has been perhaps the single most important improvement in recent years in the training of secondary school teachers.

An early statistical study was conducted in 1960 by the Bureau of Social Science Research, Washington, D.C. This study was centered on a group of 538 teachers from 503 high schools who attended summer institutes in 1957. In 251 of the schools, interviews were conducted in the fall of 1959 with principals or supervisors and with teacher colleagues of the 1957 institute participants. Approximately five out of six principals said they would consult a former NSF summer institute participant rather than another teacher when they wanted advice on new teaching techniques; three out of four said a person who had attended an institute would be given preference in assignment to a new subject. Principals also expressed strong preference for institute-trained teachers for assistance in selecting new equipment and textbooks, acting as advisers to science clubs, and serving as representatives at teachers' conferences. Participants themselves summed up the institutes' effects in the following manner: More than 80 percent said they learned new subject matter; almost 40 percent said they learned new techniques of teaching their subject; more than 33 percent gave the institute credit for their assignment to teach more advanced sections; more than 25 percent said the institute was a source of added enthusiasm or improved self-confidence; 20 percent said they had profited from the program by widening their social contacts.

On their return to their classrooms, many participants said they made changes directly as a result of their institute experience. Almost half said they introduced more advanced subject matter into their courses or broadened their coverage; about 30 percent said they brought newer subject matter into their courses; about 30 percent said they also put more stress on student participation through such devices as encouraging special projects; and about 16 percent said they were devoting more time to laboratory work and making greater use of audiovisual aids. One key finding in this study was that institute attendance had a definite cumulative effect. Of the teachers who

attended only one institute, 32 percent reported "a great deal" of improvement in their course work. The same response was given by 41 percent of the teachers who had participated in two institutes and by 59 percent of attendees at three institutes.

One measure of the effectiveness of summer institutes is their continuing, and increasing, attraction of teachers in numbers far exceeding the opportunities available:

Participation in NSF summer institutes for secondary school teachers, 1961–65

	Applications	Applicants	Participants
1961	175,860	55,714	18,812
1962	184,161	56,294	20,267
1963	176,939	56,555	20,450
1964 [1]	188,000	56,900	20,550
1965 [1]	197,700	59,400	21,350

[1] Estimated.

Another measure of the effectiveness of the institutes program lies in the evaluation by the directors of the individual institutes of their own achievements. Many directors collect written, unsigned, commentaries from their participants, and report quite uniformly on the favorable reactions of a large majority of the participants. These favorable reactions, combined with the continuing enthusiasm of their faculty colleagues who teach in the programs, cause over 90 percent of these directors to submit proposals for subsequent institutes.

The effectiveness of institutes in improving secondary school education in science and mathematics should appear in the increased capabilities of high school graduates for college work. Many college and university staff members have commented on the observable changes in their entering classes—changes they feel are attributable, in part, to the institutes attended by the teachers of these students. For example, Dean B. Roger Ray of Washington State University, has stated:

> The [NSF] institute program has been more responsible than any other factor in achieving a substantial upgrading of competence of science and mathematics teachers in secondary schools. I believe it has been the primary factor. We continually see the results in general and specific ways. Each freshman class in the university is better prepared in science and mathematics than the previous one, for instance, as shown by our mathematics placement test scores. These students are getting instruction in their basic high school courses that is more substantial and modern. We have an increasing number of freshmen who obtain advanced placement, in good part because additional science beyond the minimal requirement is being offered in the high schools by competent teachers. Frequently we can correlate the quality of the work given in a high school with a specific teacher who has participated in the institute program.

The Congress itself has recognized the effectiveness of the institute programs of the Foundation by using them as models for the institute programs of title VI of the National Defense Education Act of 1958 and title XI of the 1964 revision of the same act. These legislative enactments resulted from strong pressures from the educational world for teacher training opportunities in the nonscience areas to match the evident successes of the institutes in science.

An address of Dr. Samuel Schenberg, supervisor of science for the New York City schools, to the 1962 convention of the Association for

the Education of Teachers in Science summarizes the view we have encountered in many situations:

The National Science Foundation, through its sponsorship of summer institutes and revisions of existing courses of study on a nationwide basis, is making a highly significant contribution to the improvement of science and mathematics teaching in the junior and senior high schools of our country. The impact of these programs is already influencing the offerings of our colleges in the freshman year. In a brief period of a half dozen years the NSF by virtue of the tremendous financial resources at its disposal has demonstrated that a national agency can raise educational standards in every city and hamlet in the United States without infringing upon the rights and control of local school systems.

Thus we can say that formal evaluation devices, informal assessments, reactions of informed observers, and testimony of participating teachers and their supervisors all contribute to the continuous review of this program—and all these mechanisms point to the conclusion that this has been and remains an important and effective way of improving the scientific potential of the Nation.

I–6. In regard to NSF support of engineering, you have provided evidence to show that NSF's approval of engineering proposals and fellowships is roughly in the same ratio as its approval in the area of the physical sciences. However, the total support of the physical sciences far exceeds that of engineering. In view of the Gilliland report which emphasized a nationwide need for more engineering Ph. D.'s, do you think NSF's effort here is adequate? Should it not consider the national picture rather than just the percentage of the Foundation's own support for engineering?

I–6. In my reply to question E–19, I expressed the Foundation's general agreement with the recommendations of the Gilliland report. At the same time, I pointed out some important related matters with which the report did not deal, and the need for periodic examination and reassessment of the problems inherent in the area of scientific manpower.

In its support of engineering, as in all fields, the Foundation has consistently tried to evaluate the needs and opportunities presented on a nationwide basis. Several factors are of special significance in the case of engineering and have to be borne in mind in evaluating the Foundation's position.

1. The mission-oriented agencies, especially the Department of Defense, NASA, and AEC have direct and continuing interest in the support of engineering research. Whereas support in certain fundamental fields of science by DOD, for example, has been questioned, there has never been any doubt about the Navy's long-term commitment to the support of research in hydrodynamics and naval architecture. Furthermore, many research workers in these fields prefer Navy support, since the Navy is a primary user of new information. A highly satisfactory relationship has developed between the Navy and research workers in these areas. The same can be said of the relationship of mission-oriented agencies to engineering research activities in material sciences, aerodynamics, nuclear engineering, and many other fields. The Foundation must evaluate its role with a clear appreciation of the mutually advantageous relationship which exists between the other agencies and engineering research workers.

2. Engineering education for the past 10 years has been in a state of agonizing reappraisal. The Foundation has been watching this

process and has supported a Commission on Engineering Education, comprised of leading representatives of the profession, which is seeking to resolve some of the major problems now being faced by engineering schools. The Foundation has also made grants (to the American Society for Engineering Education) for major reassessments of the goals of engineering education, and means of achieving these goals. The report of this study has not yet been completed, but it will undoubtedly contain recommendations which if widely adopted will have substantial influence on the future of engineering education at both undergraduate and graduate levels.

3. Although the Foundation has adopted a broad definition of basic research in engineering, it is not possible under the limitations of our act to support some of the activities in engineering schools in the areas of applied research and exploratory development. In the NSF fellowship and traineeship programs, however, support for graduate students and advanced scholars is available in all areas of engineering.

The rapidly increasing production of engineering doctorates now being achieved with existing support (the annual production of engineering doctorates has approximately doubled since 1961) will undoubtedly lead to increased needs for research support in the future. About one-third of the new doctors of engineering are entering the teaching profession as young faculty members, thus swelling the clientele seeking research assistance from NSF. It is therefore probable that the need for university research support in engineering will increase rapidly in the next few years.

Since 1960 our support of project research grants in engineering has risen faster than our support in any other area (except for the social sciences). As the table we presented to the subcommittee on August 19 shows, we are currently providing more support to graduate students in engineering than we are to all the physical sciences combined. Moreover, our various surveys show that other agencies provide large amounts of support for engineering research and graduate students.

In summary, then, in relation to the overall resources available to the Foundation and its presently assigned mission, we consider that the proportionate support currently being given to research and education in engineering by NSF is appropriate. The rate of increase of research support is commensurate with the increasing needs viewed at the national level, but may need to rise in a few years. We remain ready to support more good work of high quality in engineering research, and we confidently project continued increases of our support in this important area.

I–7. In the consideration of NSF fellowships and traineeships, is personal need ever considered as part of the criteria for approval?

I–7. Personal need has not been and cannot legally be considered as a criterion in the selection of NSF fellows, since the Foundation's enabling legislation makes it clear that fellows are to be selected "solely on the basis of ability."

If we wished to make a distinction between "selection for award" and "determination of the amount of an award," it would be possible to award fellowships to the ablest applicants, but then to apply some kind of "means test" in each individual case in determining the amount of the fellowship award in that specific case. The National Science

Board has on occasion considered and discarded this possibility. The Congress arrived at a similar conclusion when it specified that all NDEA fellows were to receive the same basic stipend. As a general matter, we know of no major Federal or private fellowship program administered on a national basis which—apart from providing standard dependency allowances—applies the criterion of personal need in determining the amount to be awarded a graduate student chosen for a fellowship.

With respect to the Foundation's traineeship program initiated in fiscal year 1964, universities receive grants which enable them to appoint individuals to traineeships and it is possible that some universities take financial need into account in selecting individuals to hold these awards.

In both the NSF graduate fellowship and graduate traineeship programs the stipends and dependency allowances provided by the Foundation are identical. Each program has a permissible feature, however, which allows the universities to consider the financial need of fellows and trainees and to supplement their stipends from university funds. We know that—on occasion—universities have supplemented stipends based on the need of individuals. It is our view that the specific need of individuals for any financial assistance beyond the Foundation's basic stipends and dependency allowances can be determined best by the universities. Our policy has been to establish guidelines which will permit universities to make that decision at the local level.

I–8. In your reply to question B–6, you emphasized the 15-percent annual growth for academic research refers to the total Federal support rather than, to that of NSF alone, and that the NSF academic research budget would have to be further increased if the other departments and agencies do not sustain this rate. Because a small reduction of large mission agency research budgets could require a relatively large NSF offsetting budget increase, one can foresee requests for NSF academic research to grow at annual rates of 20 or 25 percent, which correspond to doubling times of 4 and 3 years respectively. What effect do you think such a growth rate for academic research would have on other NSF programs? Could the NSF properly administer such rapidly growing programs without major changes in organization and staffing?

I–8. Growth rates of the order of 20 to 25 percent per year in NSF support of academic research are by no means unprecedented. We do not have the specific analysis on the basis of academic research alone, but NSF support of basic research in general (most of which went to universities and colleges) rose 49 percent in fiscal year 1962 over fiscal year 1961, 37 percent in fiscal year 1963 over fiscal year 1962 and about 24 percent in fiscal year 1965 over fiscal year 1964. Thus increases of the order of 20 to 25 percent per year would not appear particularly difficult to manage effectively, although some modifications in procedure and in organizational patterns are most likely to be necessary in the future as they have been in the past. The Foundation has continually revised its procedures and its organizational structure as NSF activities have become more complex and extensive; if the Foundation is given responsibility for serving the "balance wheel" function envisaged in question I–8, I would expect that still further changes will eventually be required.

Growth rates of the order of 25 percent annually in the support of academic research should (for a time at least) be paralleled by sizable but not necessarily comparable growth rates in the other programs of the Foundation.

In my reply to the question cited above (B-6, combined with E-7, E-6, and C-6), I dealt at some length with the factors which must be considered in assessing future needs for support of education in the sciences, major research facilities and new or refurbished research laboratories.

There we pointed out the difficulty of devising a specific annual-rate-of-increase criterion for these areas of concern. We have much the same difficulty with respect to our support of national centers, national research programs, science information activities, and the like. Our past experience indicates unequivocally, however, that major increases in all these areas are highly desirable for at least a few years to come. I have no hesitancy in saying, therefore, that substantial increases in academic research should be made along with increases of a similar nature—based on specific justifications in the particular program at issue—in all of the Foundation's activities. To move forward with such increases in academic research support without correspondingly higher levels of support in other programs—or at their expense—would be to solve one problem by creating others.

As I have already indicated (above and in answer to question I-1), we will certainly have to consider new procedures, new organizational arrangements (including additional delegation of authority), and additional staff if the Foundation continues to grow in the future as it has in the past. I do not look upon these matters with any degree of alarm, however, for they represent a situation with which the Foundation has been grappling—with reasonable success—since its earliest days.

I-9. Considering recommendations to enlarge different parts of the NSF budget, or to shift emphasis within programs, would you briefly describe how the final allocation is reached in your budget requests between you as Director, the National Science Board, and your senior program staff? To what extent do the Bureau of the Budget and the OST change or cause revision of individual programs, or activities within program estimates?

I-9. As part of the budget formulation process, the staff members responsible for the program activities of the Foundation develop preliminary estimates of the funds required in their respective program areas. These estimates are reviewed by the Associate Directors and forwarded to my office. At this stage a series of discussions take place, with participation by the Deputy Director, the Associate Directors, the Comptroller, and the Budget Officer, to evaluate the program requests in relation to each other and within the general guidelines of the Bureau of the Budget.

At the point where we are reasonably satisfied that the budget request as a whole is well balanced, taking into account the needs of the various programs, we present this preliminary budget to the National Science Board. This presentation is the occasion for Board discussion of budget levels, program emphasis, relative needs, and new activities to be undertaken. The preliminary budget request is then submitted to the Bureau of the Budget for review and approval.

A major concern of the Bureau, obviously, is the total of the budget request. In addition, however, both the Bureau and OST take an interest in and discuss with us specific aspects of our activities. These discussions may result in increases or decreases for specific items as well as in the overall total. The amounts finally agreed upon are incorporated in the President's budget for submission to the Congress.

When the appropriation bill is passed by the Congress, the Foundation is required, as is every other agency, to submit a request to the Bureau of the Budget for an apportionment of the funds appropriated. The allocations to the various programs and activities are discussed with the senior staff, and my recommendations are then communicated to the Bureau of the Budget.

As part of my report to the National Science Board at each meeting, I normally include a statement advising the Board of the status of our budget request, allocations made, and major changes in emphasis among programs.

I–10. What other mechanisms, other than project evaluation by peers, might be experimented with to avoid overloading the scientific community with reviews while preserving their input into the selection process?

I–10. Although we consider project evaluation by peers to be an essential part of any process of making research grants, there are a number of ways in which the burden on the scientific community can be lightened. Among these are:

1. Prescreening of proposals is carried out by NSF staff to eliminate many proposals that are incomplete or obviously not worth reviewing because of low quality.
2. The number of mail reviews for any proposal is normally limited to three except in exceptional cases.
3. In a number of areas review by assembled panels has been limited to those proposals which are marginal in quality or have some unusual features, decisions on others being made by the NSF staff.
4. For long-term continuing programs, a full-scale review will be required only at 5-year intervals. Intermediate decisions will be made by NSF staff.

Most scientists welcome the opportunity to participate in the review process, either as mail reviewers or as members of assembled panels. When this work becomes burdensome to any individual, our staff members take steps to reduce his load. In general, we feel that a healthy relationship exists between the Foundation and the scientific community in this area.

Although we have found no substitute for the proven project evaluation by peers, we have sought and are finding (though not for the primary purpose of reducing the workload on reviewers) means of research support other than the traditional project grant. For example, "coherent area grants" are made which provide support for a number of related projects which are jointly reviewed, evaluated, and funded, thus reducing the overall total in reviewing time and effort. Institutional base grants provide assistance to an entire institution. These grants, as we have noted in other contexts, lead to an entirely different basis for distributing funds in support of academic science, and do not require any time on the part of external reviewers.

These other methods of funding science must not be considered in competition with the project support method. We believe that several support techniques of a complementary nature are desirable. The mechanisms just described, however, require a different system of evaluation and reduce the burden on scientific reviewers. The project basis of support and the evaluation by peers, however, provide a unique method which we do not think can be supplanted by other methods of evaluation and review. We nonetheless are acutely aware of the need of holding to the absolute minimum the amount of external review effort we request of the scientific community, and we intend to continue our search for ways of reducing the burden of such work on those to whom we turn for help in this area of our operation.

I–11. Considering the effect of the quality of Federal administration upon academic research, to what extent should the Foundation lead Federal agencies in the simplification and standardization of rules and regulations governing grant and contract administration? For example, Dael Wolfle pointed out recently that the NIH grant manual is more than 100 pages long.

I–11. Since the Federal Government is the chief source of support for the vast bulk of academic research, it is clear that the manner in which the Government administers its grants and contracts can exert a major impact on the conduct of academic research. From the time of its establishment to the present, the Foundation has been well aware of this important relationship and has attempted to carry out its administration of grants and contracts with the minimum of interference in the course of research, while at the same time assuring the adequacy of necessary fiscal and administrative controls.

Recognizing the importance to academic institutions of grant and contract procedures that have been simplified and standardized to the maximum extent possible, the Foundation has continually attempted to "streamline" its own procedures. Because of its unique responsibility for the broad-scale support of basic research, the Foundation believes it should exercise a leadership role (working in consultation and cooperation with other Government agencies) in developing simplified, standardized procedures governing grant and contract administration.

As a recent example of its activities along these lines, the Foundation is presently engaged in developing a new research grant report to take the place of the grant fiscal report currently required of grantees. The new research grant report has been developed in such a way that it could be adopted by other agencies, and the Foundation has been in consultation with the Bureau of the Budget regarding eventual Government-wide adoption of this reporting procedure.

The Foundation's efforts along these lines, as question I–11 recognizes, can be effective only to the extent that NSF patterns or suggestions are viewed by other agencies as worthy of adoption, because we have no authority to impose uniform practices on other agencies.

Response by Dr. Donald F. Hornig, Director, Office of Science and Technology, to Questions of the Subcommittee on Science, Research, and Development

---

1. In your statement on June 29 you testified as follows:

Major problems lie ahead which will call for stepped-up efforts to develop new and improved approaches to the planning of the Government programs for the support of academic research and for relating this research to the large science programs aimed at particular national objectives.

What major problems of this sort do you foresee?

1. The major problems which lie ahead are of the following types:

A. To meet the growing needs of the country for research and education in the sciences. Essential parts of this problem are to determine, on a geographical basis, the distribution of facilities for scientific research and education which are needed to meet social and economic needs of regions as well as the Nation as a whole; to determine how support should be allocated among universities to meet regional needs while at the same time assuring that high quality in academic research is not only maintained but enhanced and expanded.

B. To develop methods to choose meaningfully among the growing number of opportunities for further research which the present research uncovers.

C. To use research to meet the growing needs of our society for answers to questions which we now believe should be solved by national action.

2. What is the precise difference between the functions of the Federal Council for Science and Technology and the Office of Science and Technology? Do not these organizations have virtually the same personnel which also includes being active with the President's Science Advisory Committee? If this is so, is this the most efficient manner of getting a job done?

2. The Office of Science and Technology, the Federal Council for Science and Technology, and the President's Science Advisory Committee serve distinct but related functions. OST is a part of the Executive Office of the President, and its primary task is to assist the President on all matters relating to science and technology. A secondary task is to provide staff for PSAC and FCST. The function of the PSAC is to provide advice to the President by highly qualified scientists who are, with few exceptions, not associated with the Federal Government. The function of FCST is to provide a two-way link between the policy officials responsible for the major Federal R. & D. programs and the President and his office. These functions and their relationships are described below.

The Federal Council for Science and Technology is an interagency committee consisting of policy-level representatives from all the major R. & D. agencies. Its primary function is to provide a mechanism for

the coordination of R. & D. programs and policies cutting across the responsibilities of several agencies, to serve as a forum for the discussion of common problems, and as a source of recommendations to the President through its Chairman. The FCST is an advisory committee without executive responsibility, although by reaching agreement through consensus it often makes decisions in fact. The recommendations of the Federal Council incorporate the views of the agencies represented on the Council on policy matters affecting them. It both originates policy proposals, and reacts to proposals arising from other sources. In addition, the Federal Council provides a central mechanism for the establishment of interagency coordinating groups, of which there are nine, and for assessing the effectiveness of these groups.

The Office of Science and Technology under the leadership of a Director who is also the Special Assistant to the President for Science and Technology, is a part of the Executive Office of the President. As such, the primary function of the Office is to provide advice to the President on questions relating to science and technology. Many questions of science policy are not appropriately dealt with either by the Federal Council or the President's Science Advisory Committee in spite of the breadth of their activities and influence. Some of the most significant questions affect only one or two agencies, and are therefore not effectively handled by the Council. Other questions are of such a nature that the advice of PSAC is not directly pertinent. Many problems of interest to the President must therefore be handled within his Executive Office. For example, those aspects of the Federal budget affecting science and technology are reviewed within the Executive Office of the President, including participation by the Office of Science and Technology, after the primary proposals have been made by the agencies and after advice has been received from many sources. This direct involvement in decisions made by the President and within his Executive Office distinguishes the work of the Office of Science and Technology from the two advisory groups. In addition, the Director of the Office of Science and Technology testifies before Congress as a spokesman for the administration on matters affecting and affected by science and technology.

The Office of Science and Technology provides the Executive Secretary for the Federal Council for Science and Technology and for the President's Science Advisory Committee. In addition, the staff of the Office of Science and Technology provide data, draft materials and general assistance to the two advisory groups. This method of operation serves to provide effective communication and division of effort between the groups involved, but it does not weaken the essential distinction between them.

3. You spoke of the Federal Council for Science and Technology as "an indispensable forum." What has been the frequency of meetings of the Federal Council, by fiscal years, since 1960?

3. The number of formal meetings of the Federal Council for Science and Technology have been as follows:

Calendar year:	Number
1960	11
1961	10
1962	12
1963	12
1964	13

The committees and panels of the Council serve to extend the forum function by broadening the range of subjects considered, expanding the detail of consideration and extending the number of people involved. In fiscal year 1964, 89 meetings of the 11 Federal Council committees were held, and the panels of these committees held approximately 250 meetings.

In addition to its own meetings and those of technical committees and panels, the Council has used other groups to amplify the forum function. For example, the standing committee of the Council, which pays particular attention to the effectiveness of the Federal laboratories, has a major function—the sponsorship of symposia on factors affecting laboratory operation. Each of these symposia has drawn together about 100 persons with responsible positions in the management of R. & D. laboratories. Most of those who attended were from outside the Washington area.

The first symposium, held in October 1963, dealt with current problems in the management of scientific personnel. The proceedings were later published.

A second symposium, held on April 13–14, 1964, reviewed the technical information role of the Federal laboratories.

The third symposium held on December 7 and 8, 1964, dealt with the environment of the Federal laboratory and management problems in the Federal service. This symposium, like the first in the series, was jointly sponsored by the Federal Council and the Civil Service Commission.

The actions recommended at the symposia are now under study by the FCST Standing Committee, the Civil Service Commission, and the agencies concerned.

4. Should the National Science Foundation have broader authority to act more as an operating agency? If so, why?

4. The primary mission of NSF is to insure the health of basic research and scientific education throughout the country. Its underpinning of basic research and education can be accomplished most effectively through support of the universities using the grant or contract mechanism. However, in support of its primary mission it supports extensive extramural operations such as NCAR and the Mohole project.

At the present time I am not in favor of in-house laboratories in NSF for the conduct of basic research. On the other hand, an operating role of this kind for NSF in the future should not be precluded as a possibility if required to meet special needs that cannot be met otherwise. However, this should not be allowed to detract from its support of basic research in the universities.

5. Is the Foundation's role in shaping, coordinating, and evaluating national science policy—or rather, its lack of a role in this matter—a healthy arrangement?

5. Before answering this question directly I should like to make clear that there is no such thing as a single national policy for science. National science policy is composed of a mosaic of related segments.

The NSF has an important role in the shaping and evaluation of a number of these segments of national science policy. It has a unique responsibility among the Federal agencies for the advancement of basic science, per se, including education for science. Thus, in formu-

lating its own programs in science and science education, the Foundation must take into consideration the support programs of other agencies and their cumulative effects on the universities. The NSF is expected to and does generate policy proposals for the entire Government which are given particular weight because of the unique position and mission of the agency. The function of generating policy proposals is different from that of assisting the President in achieving coordinated Federal policies for the promotion of basic research and education in the sciences. The latter function was assigned to the Director, Office of Science and Technology by Reorganization Plan No. 2 of 1962 because it was recognized that this task can be effectively carried out only from the Executive Office of the President. Separation of those two aspects of policy—initiation as contrasted with establishment and execution—tends in fact to strengthen the policy role of NSF.

6. Are too many Federal agencies today involved in supporting basic science grants and science education? Is there duplication here? Might not the Foundation assume a more central, if not exclusive, role in this regard? Who coordinates this area?

6. We do not believe there are too many Federal agencies involved in supporting basic science grants and science education. Indeed we feel that the national interest would be served if certain other agencies not now much involved in the support of extramural research were to increase their involvement in basic and applied research outside the Government through the support of selected projects in universities and other research organizations in fields appropriate to their mission. For example, the Departments of Interior and Commerce are less than optimally effective in fulfilling their missions because they do not have sufficient interaction with the general scientific and engineering community outside the Federal Government. Diversity of support is important in insuring that research opportunities are not overlooked, and that parochial biases which inevitably develop in individual agencies will be canceled out in the overall picture. The argument for diversity applies to private, State, and local, as well as Federal sources of support.

There are two reasons to support basic scientific research, based on the needs of society. The first relates to the internal needs of science and of science education as determined primarily by areas of scientific knowledge. The National Science Foundation supports research primarily on these terms. The second is embodied in the missions of the various Federal agencies, and depends upon the fact that progress toward many well-defined national goals is limited by the lack of basic knowledge and understanding about certain groups of scientific questions. Support of basic research thus constitutes an essential part of the national programs in health, defense, and space. Because the line between basic and applied research is constantly changing and new opportunities are constantly emerging from basic research, these agencies cannot depend exclusively on another agency to support the generation of the knowledge they may need. They must not only keep in contact with the best thinking going on in the universities and elsewhere, but also encourage through support of basic research the growth of certain broad areas of knowledge in accordance with priorities related to their own mission and not just the development of science and education. Duplication need not exist if the programs are effectively

coordinated. Furthermore, the nature of basic scientific research is such that professional penalties are attached to duplication, whether unwitting or not, and the system of project selection by panels of peers further tends to detect and eliminate potential duplication.

The greatest danger of duplication may occur in the case of classified material which is not exposed to open scrutiny and criticism. The likelihood of this occurring is greatest in in-house laboratories.

OST is charged with coordinating research and development activities. One of the largest and most difficult questions is what activities should be coordinated and to what extent. Agency heads and other senior officials confer with each other and with personnel of the Executive Office of the President, as appropriate, on major policy questions and on projects involving large sums of money. At the working level, frequent contacts assure coordination between agencies, as for example NSF and NIH through meetings of program directors and exchange of information among them. The Science Information Exchange is another mechanism for coordination and avoidance of duplication.

In those agencies in which project and program review is carried out by panels of peers such as study sections, an effective means exists for avoiding duplication. This mechanism is used in NSF and NIH.

It is conceivable that NSF might take a larger role for the whole Government in coordination and prevention of duplication but I question whether this course would be wise.

7. Have our science programs been effectively utilized to further the U.S. position internationally? Should NSF assume a more active role in the support of international science programs?

7. Science and technology have a large role to play in furthering the foreign policy objectives of the United States. The problems which involve science and technology are more or less universal in character and provide a basis for mutual understanding and for cooperative action that often transcends political differences.

International cooperation in the field of science and technology is pursued in a wide variety of ways and through many channels. Many such activities are conducted through the medium of intergovernmental programs, involving a number of different U.S. Government agencies according to their spheres of interest. The Atomic Energy Commission, for example, is engaged in a number of cooperative activities related to atomic energy pursuant to bilateral agreements under the atoms-for-peace program, including arrangements with Euratom and the International Atomic Energy Agency (IAEA). AEC also carries out exchange programs with the Soviet Union. The Department of Defense provides funds for basic and applied research under cooperative agreements entered into with friendly governments, particularly those of Europe. The National Institutes of Health have supported health research programs in many countries. The Department of the Interior engages in cooperative programs relating to natural resource development. The Agency for International Development undertakes programs for institution building in areas of science and technology as part of its developmental programs for newly developing countries.

The Department of State has found various ways of utilizing science and technology to promote better international relations. The exchange agreements with the Soviet Union which are under the

supervision of the Department of State, have contributed to the improvement of international understanding, and the scientific exchanges under the agreements have made a significant contribution to this result. The United States-Japan Committee on Scientific Cooperation is another example of the cultivation of better international understanding through science. In both of the activities of the Department of State just listed, the National Science Foundation has played an important role, through the funding of certain of the scientific exchanges with the Soviet Union, in the one case, and through the support of the United States-Japan Committee, in the other.

Another form of international cooperation in the field of science and technology is conducted by international organizations. American scientists and representatives of American governmental agencies participate in a number of scientific and technological undertakings sponsored by the various technical agencies of the United Nations, such as the Food and Agriculture Agency (FAO), the World Health Organization (WHO), the World Meteorological Agency (WMA), the United Nations Educational, Scientific, and Cultural Organization (UNESCO), and others. The U.S. Government also participates in scientific programs of regional international bodies such as the Organization for Economic Cooperation and Development (OECD), the North Atlantic Treaty Organization (NATO), and the Organization of American States (OAS). These activities on the part of the U.S. Government fall under the direction of the Department of State with support derived from a number of other Government agencies that are concerned.

The National Science Foundation has lent support to U.S. participation in a number of international scientific exercises and operations, such as the International Geophysical Year, the International Indian Ocean Expedition, the International Hydrological Decade, the International Year of the Quiet Sun, the upper mantle project and the antarctica program.

The United States has also contributed to the support of a number of nongovernmental international scientific bodies, such as the International Union for Pure and Applied Chemistry and the International Union for Pure and Applied Physics, which are grouped together in the International Council of Scientific Unions (ICSU) on which the United States is represented by the National Academy of Sciences.

Mention should also be made of the innumerable contacts that are made in the field of science and technology directly between scientists in research laboratories in universities and in private industry, and through attendance at scientific meetings of varying degrees of specialization sponsored by governments or by the governmental and nongovernmental international technical organizations referred to above. The fostering of personal relationships between scientists in the fields of basic research and applied technology is essential to the wider application of scientific progress and the development of better international relations. The importance of the role of the National Science Foundation in providing travel funds which enable U.S. scientists to participate in such international meetings and to develop useful contacts abroad merits recognition.

In summary, the total effect of this wide range of activity on the part of agencies and organizations within the U.S. Government in the

field of international science and technology has been clearly beneficial and is making a significant contribution to the achievement of U.S. foreign policy objectives.

The full potential of science and technology as a means of promoting international understanding and good will has not yet been realized. We are constantly seeking better ways to improve our international relations through science.

The National Science Foundation has played an important part in the accomplishments in respect to international science programs carried out to date. We hope and expect that the NSF will also look for ways to develop new and improved programs to achieve our objectives in the area of international science.

8. Have Government-wide standards been established for scientific fellowship awards and stipends? If so, who establishes them and what are the standards?

8. Government-wide standards for fellowship awards and stipends have not been established formally. However, levels of support for the basic stipends and allowance of most predoctoral and postdoctoral fellowships generally exist through understandings among the agencies concerned. These levels are agreed on administratively. The small variations that exist derive in part from differences in congressional authorizations.

Predoctoral fellowships presently provide between $2,400 and $2,800 for a full year of academic study (depending upon the number of years past the bachelor's degree) plus $2,500 to the institution to cover part of the costs of education. The National Defense Education Act predoctoral fellowships whose stipends and allowances are set by law also conform to this pattern; NASA provides an additional allowance which may be used to increase stipends in certain circumstances and pays the full educational costs to the institution.

Beginning in 1952 the NSF coordinated the stipends and allowances through annual and later semiannual consultation with the agencies granting fellowships. More recently the Bureau of the Budget has requested the Commissioner of Education to assume this task in view of the Office of Education's broad responsibilities for educational policies.

I believe that there should be room for experimentation in the granting of fellowships. This has been possible under existing arrangements with the elimination of inequities accomplished by administrative consultation.

9. How can the relatively low science education budget of the National Science Foundation act as a balance wheel against the large sums spent in institutions of higher learning by mission-oriented agencies? Should not the NSF have a say in how all Federal basic research funds are allocated—because of their close link to science education?

9. It is difficult for the NSF to balance fluctuations in support by other agencies when its budget is such a small proportion of the total support for science and technology. We would like to see its proportion increased somewhat. NSF should have some concern and interest in other agency programs in order to do its own job effectively. NSF can assist in identifying areas of research opportunity, but the allocation of funds to meet the technological purposes of another agency is best decided by that agency with policy guidance from the President.

The present system of interaction between the universities and the agency is the best guarantee that other agency programs will also help education.

Data gathering and analysis by NSF is of the greatest importance in obtaining a comprehensive picture of university support by mission-oriented agencies. This function needs to be steadily improved if distortions or gaps are to be detected and remedied. In this respect NSF plays a crucial role in the process of determining and analyzing allocation of funds for the support of basic research.

10. Do you consider the present balance between project support and institutional support by NSF to be satisfactory?

10. Throughout the first decade following its establishment NSF engaged predominantly in project support. This was a logical and necessary response to both needs and opportunities. In recent years there has occurred a significant evolution with the support of broad programs of science and education, and institution building through the award of development grants. Institutional grants have important implications for the future development of science and education especially through the creation and strengthening of centers of scientific excellence in all regions of the country. I believe that this program should be expanded in the future, but not at the expense of project support which is essential not only for the advancement of scientific knowledge but also for the education of the oncoming generations of students. On the basis of careful estimates and forecasts it has been calculated that for the near future the needs of basic research and scientific education can be adequately met only if there is an annual increase in the funding of academic research. I believe that these estimates are sound and that this annual increment is necessary if we are to maintain our scientific leadership and give full opportunity to our youth.

11. In relation to scientific and technical information, who decides to make the allocation as between Federal and non-Federal data? What is the authority for this decision?

11. The answers to this question are subsumed under the response to other questions. We are omitting it, therefore, from this submission. (Mr. Knox of this office and the staff of the subcommittee have agreed on this procedure.)

12. The National Academy of Sciences in its recent report, "Basic Research and National Goals," emphasized 15 percent annual increase for support of basic research. Where will the support for the increased student body and the needs of institutions come from? Should one put priority in the increase in funding for basic research ahead of increased funding to meet student enrollments? With this Federal support doubling every 5 years, won't other sources of university funding shrink rapidly in proportion? Is this good? Is this the result of a policy study? If so, is it available?

12. A major portion of the extra funds for growth of basic research are used to provide significant research opportunities for new faculty, for graduate students, and other trainees and increasingly even selected undergraduates, as university enrollments increase sharply. In general, funds for formal instruction—including classrooms and faculty expenses—are easier to obtain from non-Federal sources than are funds for research. Funding for the capital needs of institutions will be

further aided by the Federal facility programs which normally call for matching. Funding for research needs of the increased graduate student enrollment will help meet the needs for undergraduate students by freeing resources which the institutions would otherwise be compelled to devote to research. Whether an additional Federal role for meeting undergraduate research needs is called for deserves careful consideration by the Congress and the Executive.

There is no evidence that the increase in funding which has occurred in the past has caused absolute shrinkage of other sources of support, although the proportion of Federal funds in the educational system has increased. The 15 percent growth requirement for academic research implies an annual increase of $150 million as compared with an annual increase of over $1 billion which has occurred for all forms and sources of support for higher education. We agree that it is important that non-Federal sources of support continue to grow, so that the institutions of higher education in this country do not depend too exclusively on Federal funds. In point of fact, non-Federal sources of support for science and science education are continuing to increase substantially.

Comprehensive current national figures are not available at the present time. A survey of sources of support on a sampling basis was carried out by NSF in 1958. During the past year NSF has made a national survey, institution by institution. Preliminary results will be available in 6 to 8 weeks but analysis will not be completed for approximately 6 months.

For some years NIH has conducted surveys of the national expenditures for medical research. The figures shown in table I indicate that for this very large segment of research support the infusion of extensive Federal funds has not caused private support to dry up. Instead, private support has increased more than six times the level of support in 1947. The expenditures by industry, which are chiefly, but not exclusively in-house, have increased by approximately twelvefold during the same interval.

TABLE I.—*National expenditures for medical research, 1940–64* [1]

[In millions]

Sources of funds	1940	1947	1957	1959	1960	1961	1962	1963 (estimate)	1964
Total	$45	$87	$440	$648	$845	$1,045	$1,290	$1,470	$1,672
Government	3	27	239	368	471	604	819	969	1,102
Federal	3	27	229	351	448	574	782	924	1,052
State and local	(2)	(2)	10	17	23	30	37	45	50
Industry	25	35	126	190	253	312	336	360	415
Private support	17	25	75	90	121	129	135	141	155
Foundations and health agencies	12	15	42	49	76	77	78	79	90
Other private contributors	(2)	(2)	5	10	12	15	18	21	22
Endowment	5	10	19	19	19	19	19	19	19
Institutions' own funds	(2)	(2)	9	12	14	18	20	22	24

[1] Covers only medical and health-related research; such activities as research training and construction are not included. Beginning with 1960, data for the non-Federal component have been improved and therefore are not strictly comparable with those for prior years.
[2] Not available.

13. The point has been brought during the hearings that certain research projects are referred to the National Science Foundation by other Government agencies. This raises the question of how one deter-

mines if a certain research project should be funded, say, by agency X, agency Y, or both. More specifically:

(a) What guidelines or criteria has your agency established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the agency's jurisdiction and, therefore, should, or should not, be supported by the agency?

(b) If written criteria have been established, please submit a copy thereof to the committee.

13. On small projects, decisions as to whether funding is appropriate for a certain agency depends on a decision by a program officer as to the relevance of the proposed project, the funds available, and the rest of the program supported by the agency. In the cases of major programs, such as large telescopes, high energy accelerators, oceanographic ships, decisions are made by the President in conjunction with affected agencies. The decision is made on the basis of relevance to a particular agency program, and a judgment as to the experience in management of the agencies involved.

(*a*) OST has not set up general guidelines or criteria to aid grant or contract administrators to determine whether particular research projects should be supported by a given agency. One can define areas of science that are related to the missions of an agency but those may overlap particularly in the case of basic research that is broadly relevant to an agency's mission. As noted in the reply to question 6 mechanisms exist to minimize duplication of effort. A more difficult problem is to assure that important areas of science do not go without support because they are not directly relevant to the mission of an existing agency.

(*b*) Written criteria have not been established.

14. What agency of Government, if any, has responsibility for the coordination of Federal research and development in the three fields of air pollution, soil pollution, and water pollution? Is such coordination a proper role for the National Science Foundation?

14. The Clean Air Act, as amended, gives explicit instruction to the Department of Health, Education, and Welfare for coordination of Federal research and development in the field of air pollution. Water pollution control is also vested in the Department of Health, Education, and Welfare, but the congressional mandate for coordination of research and development in this field is somewhat less clear. At the present time work going on or supported by several agencies involves research on the effects of water pollution. Health, Education, and Welfare does maintain awareness of other research and there appears to be little overlap. No agency has specific legislative authority for soil pollution research and development. Work that is carried out at present is mostly within the Department of Agriculture or under its general cognizance. Some small amounts of research related to the effects of soil pollution, especially on micro-organisms, may be carried out in other agencies.

Coordination of research in the three fields of air pollution, water pollution, and soil pollution would not appear to be an appropriate role for the National Science Foundation. Enforcement responsibility for control of air and water pollution is vested in Health, Education,

and Welfare and development work associated with pollution abatement seems most appropriately located in the organization with enforcement responsibility. Research on the effects of pollutants would seem to be best left in the agencies responsible for the resources affected. For example, effects on human health in the Public Health Service, effects on fish and wildlife in the Department of Interior, effects on domestic animals and crops in the Department of Agriculture. Little overlap is likely to occur since the responsibilities are quite different in each agency. It is possible that there may be problems that are so extensive in scope that they do not fall to any single agency and thus are not considered by any agency.

Most areas of pollution research and development are problem oriented and would be foreign to the usual activities of NSF in support of basic research and science education.

15. You stated that NSF is the only agency with a broad enough interest to undertake a central planning responsibility for tying together the separate agency systems for assembling and disseminating scientific information. (You used the analogy of the Bell System tying together many independent telephone companies.)

(a) Would you please discuss in greater detail exactly what you had in mind and how it compares to what the NSF is doing in this area now?

(b) Would it require a change in NSF legislation?

(c) Could it include privately owned data gathering services?

15. It is too early to discuss in greater detail the specific functions envisioned for an agency which would have a central planning responsibility in tying together the separate agency systems for disseminating scientific information, and for recommending actions for the nongovernmental sector. Our ideas in this connection will become clearer when two contractual studies presently underway unde the auspices of the Committee on Scientific and Technical Information (COSATI) of the Federal Council for Science and Technology are completed within the next 5 months. Until that time, it is not possible to determine whether a change in NSF legislation would be required. The responsibilities for overall planning, organization, and evaluation of the Federal Government's information programs, however, are so demanding that it is unlikely that the existing NSF organizational structure would provide an adequate mechanism for discharging these responsibilities. A central planning responsibility would of necessity include privately operated services which constitute such a large segment of total scientific information activities.

16. When the NSF was created in 1950 with a budget limited to $15 million, the National Science Board could, presumably, exercise close supervision over the workings of the Foundation. Since that time, the budget of the Foundation has increased to about $480 million, and the Board has delegated much of its authority to the Director, keeping for itself the authority for major policy decisions. In effect, then, the Board serves as a sort of Board of Governors, and is the only such nonregulatory agency with this form of dual (Board and Director) authority and responsibility. The question then arises, Is it in the best interest of the country and of science in general to still maintain this dual authority, or would it perhaps be better to have the Director solely responsible for the operation of the Foundation, and

have the Board serve in an advisory capacity to the Director (a National Science Advisory Board)?

16. The membership of the National Science Board has performed important functions in the formulation and implementation of the programs of the Foundation. It brings to the Director diverse points of view and experience from a variety of institutions and organizations outside of Government essential to the development of balanced programs. Clearly, if it were not established as a governing body, there would need to be created an advisory committee to the Director. While there is no evidence that the Board's authority for major policy, program, and budgetary decisions has impeded the initiative or effectiveness of the Director, it is appropriate for consideration to be given to the possibility of recreating the Board as a statutory advisory committee appointed by the President.

The statutory status and Presidential appointment of the Board have facilitated recruitment of outstanding public members and their investment of substantial time in Foundation affairs. During the past 2 years the Board has undertaken studies in depth of policies and long-range plans that should guide the activities of the Foundation, and we regard this as a welcome expression of the Board's involvement in strengthening the role of the Foundation in assuring the health and vigor of American science.

17. An early policy of the Foundation was to use grants to broaden the geographic distribution of support funds to many more institutions than those primarily supported by other Federal agencies. Early grants for research facilities, however, were made to major centers (Harvard, MIT, Michigan, etc.)

(a) Should the Foundation devise and adopt a deliberate policy of distribution that is counter to that of other Federal agencies?

(b) Has the situation in U.S. science changed sufficiently over 15 years that the Foundation should today avoid support of existing centers of excellence?

(c) Would the impact of the Foundation be greater under such a policy?

17. (*a*) When the NSF was established there was a pressing need to build up our national capabilities in basic research as rapidly as possible consistent with the requirement that only work of high quality would be supported. It was natural and proper, therefore, to build strongly on existing foci of excellence in our leading institutions, while at the same time, through project support to highly qualified investigators in institutions throughout the country, to create new foci of excellence.

We are now in the process of developing centers of scientific excellence on a national scale, building on the programs of NSF, NIH, and other agencies. The science development program of NSF has made development awards to 10 institutions during the past fiscal year (Case Institute of Technology, Western Reserve University, University of Oregon, Washington University, Rice University, University of Arizona, University of Colorado, University of Florida, University of Rochester, University of Virginia).

I do not believe that NSF should adopt a policy that is counter to that of other Federal agencies, but rather that advantage should be taken of the programs and resources of other agencies to work collabo-

ratively with NSF in developing new centers of excellence as well as strengthening existing institutions.

(*b*) Since the existing centers of excellence set the standards of quality and produce the people that migrate all over the country to staff other universities and industry, and since the new knowledge they produce is readily available nationally, I do not believe that existing centers of excellence should be penalized in the competition for Foundation funds for research where scientific merit is the major criterion for choice. When programs for adding additional centers of excellence are involved, then, of course, the major centers should not be considered.

(*c*) If the Foundation had a policy of not supporting excellence wherever it existed, I believe the effect on the quality of U.S. science would be disastrous, and the source of high-quality people to staff the developing centers would also dry up. The open competition for project grants purely on the basis of quality provides a standard against which we can measure our success in building new centers and against which university administrations can judge the quality of their own institutions and identify their own strengths and growing points.

18. Associated Universities, Inc., operates the National Radio Astronomy Observatory on a cost-plus-fixed-fee contract. Similarly, University Corporation for Atmospheric Research and Association of Universities for Research in Astronomy, Inc., also not-for-profit organizations, operate National Center for Atmospheric Research and Kitt Peak, respectively.

(a) What special competence do these not-for-profit organizations have to operate and manage these centers?

(b) Should the Foundation operate these centers as in-house laboratories?

18. (*a*) Associated Universities, Inc., had shown competence in the management of Brookhaven National Laboratory for the Atomic Energy Commission when it was chosen to manage the National Radio Astronomy Observatory. The other two corporations were set up on the successful pattern of AUI to manage NCAR and the Kitt Peak National Observatory to assure that the users of these facilities for basic research would have a voice in their management and also to provide the necessary flexibility so that these expensive installations can be responsive to the needs of the scientific community for facilities of high quality.

(*b*) All the centers operated under contract for NSF were created partly to serve the needs of the university scientific community, from which a substantial fraction of the users of the facilities are drawn on a visiting basis. It would be more difficult to provide flexibility of operation and the necessary responsiveness to the needs of the user community were the facilities operated as in-house laboratories. There are no successful precedents for in-house operations to serve purposes of this nature and it seems unwise to depart from a successful pattern of operation which enjoys the strong support of the academic scientific community which it is designed to serve. The experience of the AEC in broadening university representation in the management of the Argonne National Laboratory and in developing plans for management of the proposed 200-billion-electron-volt accelerator are further precedents having relevance in this connection.

19. Scientific talent in Government is concentrated, of course, in the executive branch. Do you believe that the scientific disciplines, including mathematics and engineering, should have more representation in our legislative bodies? Has any effort been made by anybody to attract more scientists and engineers into politics? How might we go about inducing technically trained people to run for public office?

19. A wide range of talents is obviously desirable in the membership of our legislative bodies. However, I do not believe that because a person has a scientific background he is therefore peculiarly qualified as a legislator. This is true of legislation within his own area of scientific knowledge and more so in other areas where he is as much a layman as anyone else.

I do not believe we should try to induce technically trained people to run for public office unless they have qualities over and beyond their scientific background which qualify them to serve. Within this framework, however, I believe that legislators of high scientific and technical competence can make significant contributions to the deliberations of the Congress.

20. What function does the Science Information Council perform? Does its function conflict with those of the Committee on Scientific and Technical Information?

20. According to title IX of Public Law 864, 85th Congress, the duty of the Science Information Council is "to advise, to consult with, and to make recommendations to the head of the Science Information Service." The functions performed by the Council follow the statute very closely. The Head, Office of Science Information Service, seeks the advice of the Council on many matters of interest to his office.

The functions of the Science Information Council (SIC) do not conflict with those of the Committee on Scientific and Technical Information. The functions of SIC are to consider matters of interest and concern to the National Science Foundation; the functions of COSATI are to consider matters of interest and concern to the entire Federal Government.

21. Users of scientific information seem to be confused as to what Federal resources are currently available to them. Would the National Science Information System be more effective if the numerous and varied existing Federal scientific information centers were consolidated in one location?

21. I do not believe it is desirable to consolidate in one location the various Federal scientific information systems and services because it is highly unlikely that consolidation would result in more effective interaction between the user and the information source. An information system should not be thought of as a repository service which passively links facts to people who need them. Information transfer is an active and not a passive process. There must be extensive interaction between provider and user. This is well demonstrated by the effectiveness of oral communication which is efficient because it is pointed and directly responsive to queries.

Consolidation would also be undesirable because scientific information needs a focus in the agency charged with its development and diffusion in response to the needs of a particular user clientele, whether governmental or private.

In this vein it may be observed that the existence of the Library of Congress with its extensive collections and comprehensive cataloging does not diminish the need for many other libraries, both general and specialized, in universities, in industry, and in communities.

22. Both the National Science Foundation Act of 1950 and the National Defense Education Act of 1958 avoided any mention of "coordination" of the scientific information activities as a responsibility of the Foundation. The Presidential Scientific Advisory Council report of January 10, 1959, the January 22, 1959, letter of the President, and Executive Order 10807 of March 13, 1959, specifically recommended and assigned coordinating responsibility to the Foundation.

(*a*) *Was there a difference of opinion during this period between the Congress and the Executive Office as to the viability of an assignment of coordinating responsibility to the Foundation?*

(*b*) *Was any attempt made in the executive branch during this period to define what was to be meant by "coordination" of science information activities?*

(*c*) *Did the Foundation make any effort to discharge the Presidential assignment of coordinating responsibility or did it simply continue to follow the statutory authority given it by the 1950 and 1958 legislation?*

22. Although the National Defense Education Act of 1958, title IX, did not mention "coordination" of scientific information activities as a responsibility of NSF, the concern of the Congress during 1958 for a more effective, coordinated system of scientific and technical information within the United States was frequently expressed. (See especially hearings before Senate Committee on Government Operations on S. 3126.) The climate of opinion generated by the launching of Sputnik I in late 1957 was highly favorable toward a single agency undertaking a coordinating role within the executive branch in scientific and technical information. Upon recommendation of the President's Science Advisory Committee on December 7, 1958, the President directed that NSF take the leadership "in bringing about effective coordination of the various scientific information activities within the Federal Government." This directive was in line with the prevailing thought both within the executive branch and in the Congress during this period.

During the initial years of the Office of Science Information Service within the National Science Foundation, considerable efforts were made to define its role in "coordination" of science information activities. On several pressing problems, such as translations and the establishment of a page charge policy, NSF took the leadership within the executive branch. In effect, NSF coordinated Federal agency information programs with respect to these two specific areas. In other specific areas, such as dissemination of federally produced technical reports, coordination by NSF proved unworkable. This was mainly due to the diversity of statutes for the principal research and development agencies, directing them to provide for effective information acquisition and dissemination in relation to their missions.

A subsidiary but not unimportant factor was the difficulty confronting a small, newly established agency in attempting to coordinate the information activities of large, mission-oriented agencies.

With the establishment of the Federal Council for Science and Technology and its Committee on Scientific and Technical Information, renewed emphasis was given to interagency program coordination.

23. What was the purpose of giving the weather modification program to the NSF in 1958 rather than to some other Government agency?

23. Considering the state of the science of weather modification, and the capability of various agencies to manage research programs in this field, it was advisable to give the responsibility to NSF at that time. A research program rather than an operational program was clearly indicated.

24. From the standpoint of objectives, program control, and management, which of NSF's programs do you consider to be the best? Which the least useful? What are the Foundation's notable weaknesses or deficiences, and how may they be corrected?

24. The programs of NSF are under continuous review by the National Science Board, which in consultation with the Director, must make decisions as to the priorities of programs and their level of support. I believe that this system, coupled with "peer group" assessment of individual projects and programs, has enabled NSF to maintain high standards of quality in the work it supports. There is no evidence known to me which would indicate that there are variations in quality among programs. Because its funds have always been limited, NSF has of necessity centered its support on high-quality projects.

The weaknesses in the NSF program are a reflection of the state of national planning for the support of research and scientific education. NSF cannot remedy apparent deficiencies singlehandedly except to a limited degree because many agencies of Government as well as the whole private sector are involved.

It has been charged that NSF has not been vigorous enough in forward planning. In recognition of the needs during the past 2 years the planning unit has been reorganized and one of the three major committees (III) of the National Science Board has concentrated on long-range planning.

Among the greatest weaknesses of NSF have been insufficient funds and personnel resources to carry out the directions laid down in the act which established the Foundation.

Response by Dr. Frederic Seitz, President, National Academy of Sciences, to Questions of the Subcommittee on Science, Research, and Development

1. Would you comment on the interrelationship between the National Academy of Sciences, the National Science Foundation and the President's Science Advisory Committee—where members of the Academy may also be officials of NSF or its Board and/or members of PSAC? Is there not a relatively small group of people here who control a good deal of what research is or isn't supported by NSF?

1. Since membership in the National Academy of Sciences is determined on the basis of elections held by its membership in such a way as to single out a segment of those most proficient in scientific work, it is not surprising that the same individuals will be found in a number of posts requiring outstanding qualities based in science. Thus, the President's Science Advisory Committee is made up almost entirely of academy members. Many Academy members serve on the Science Board of the National Science Foundation. Similarly, a number of distinguished Government officials holding positions in which profound knowledge of science is vital to their work are members of the Academy. I do not believe that this should be regarded as surprising or unnatural in any way. Members of the Academy, of course, have a profound dedication to science and its progress which guarantees, in effect, that a certain fraction of them will be asked to serve the Government in a variety of ways. Since competence and talent are limited in any society, it is inevitable that a few scientists will be asked to serve in more than one way. Examination will show that such individuals invariably have remarkable talents, exceptional experience, and unusual dedication.

In relation to the dangers that might be associated with such overlap of responsibility, it should be emphasized that most decisions reached by the advisory groups on which Academy members serve are made as result of extensive debate involving many individuals with a wide variety of viewpoints. In my own experience, I have seen no instance in which a person of this caliber serving on several advisory committees has shown any significant tendency to bias his recommendations. On the contrary, persons serving in several capacities are usually those whose advice is most valuable. They usually come to the conference table with the broadest perspective.

2. The National Academy of Sciences has done much to establish America's eminent position of scientific technology. Have our great achievements in science since World War II enhanced our country's position in world leadership generally—for example, politically or socially? If so, in what manner and to what extent?

2. Prior to World War I, the United States was admired abroad for having produced many brilliant inventors and technological innovators, but we were regarded as backward in basic science. There was, in

effect, a large differential in science between the United States and certain countries across the Atlantic Ocean. Between World War I and World War II we edged ahead in basic science because our educational system was basically sound, our ideals were on the whole excellent, and both private and State money became available in increasing amounts for basic science. In addition, the refugee scientists from Western Europe acted as catalysts in an inherently healthy system. The great technological achievements of World War II on this side of the Atlantic, followed by the generous support of science by the Federal Government during the last 20 years, had the effect, judged by almost any standard, of moving our science to the front ranks, a fact realized throughout the world. Broadly, in many countries, the United States is regarded as a leader in world science. There is no doubt that our position in science has greatly enhanced our status abroad politically because of its implications of power.

The world leadership of the United States is recognized not only in the physical sciences that contribute to the advancement of technology but also in the life sciences on which depend the constant improvement of agricultural and medical practice. Progress in the life sciences in the past half century has provided the means to bring under control the mass infections and nutritional diseases on a global basis and has actually achieved this control in the more advanced countries. The result has been that in these countries the problems of medicine have shifted from the diseases of infancy to those of the degenerative diseases in an aging population, and the protection of that population from the stresses of urbanization and of a technological environment.

It might be added that leadership in research cannot be achieved without an excellent educational system, particularly at the graduate level. U.S. accomplishments in science are, I believe, recognized as testimony to our system of education and the access it has afforded to our young people from a wide variety of backgrounds who wish to pursue careers in science.

3. How do we determine the future long-range demand for scientific manpower so as to assure meeting this demand through the support of science education? What are the basic problems in meeting our national goals on science manpower? Which agency should be responsible for maintaining statistics on scientific and technical manpower?

3. It is my personal opinion that since our science-based technological society is becoming ever more complex and sophisticated, we shall need all the highly trained talent in science and engineering that we can produce. A study of university enrollments shows that the fraction of students going into science and engineering is not increasing significantly with the passage of time. This means that the supply of good scientists and engineers is and will be sharply limited. Nationally, we should do whatever we can to encourage good students to advance to the Ph. D. level or its equivalent in graduate science and engineering. My personal opinion is that such a program will return both tangible and intangible dividends to our Nation.

The basic problem in achieving our national goals in science manpower apart from money, which is not necessarily the biggest obstacle at present, is that relatively few men and women have talent for and

interest in science and engineering, coupled with the incentive to invest the many years of arduous work needed to become highly proficient.

It seems to me that the National Science Foundation, the National Institutes of Health, and the National Academy of Sciences should work in cooperation with other agencies to maintain statistics on scientific and technical manpower. Each of the three organizations will furnish its own particular viewpoint and contribution to the study of manpower. In addition, the Office of Science and Technology should maintain a deep interest in correlating and analyzing the results of such manpower studies.

4. Is there significant degree of competition in our universities between the science research laboratory and the classroom for the services of our best scientists? Do you see any danger of turning our colleges—that is, their science and engineering departments—into great research laboratories and away from education institutions?

4. In the range of my experience scientists in universities have a deep interest in educating the young, and thus take their classroom work very seriously. Since our society is a very complex one, placing heavy demands upon our good scientists and engineers, most outstanding faculty members have a variety of responsibilities. In addition to classroom teaching and research, they often have responsibilities in university administration and to their local governments and the Federal Government. In addition, some may be called upon to advise industry and other private organizations in ways that obviously advance the national welfare. I believe that matters are reasonably balanced at present and that most outstanding faculty members spend about as much time in the classroom as the conditions of the day permit. Obviously, the situation is not perfect. It might be improved if the good scientists found it possible to spend somewhat less time making certain that the contract support they receive is continued as agency policies change from one period of time to another. This, however, is an exceedingly complex issue which should be reviewed in a broad and comprehensive way.

Above all, I should like to stress the fact that any move to "send the professors back to the classroom" by "cutting out their research" would be sheer folly. Good academic research, which is closely linked to the teaching responsibility at present, is absolutely indispensable to the welfare of our society. Any studies of ways to make the faculty scientist more effective should focus upon techniques for aiding him in both teaching and research, since the two are intimately coupled.

5. What is known about the size and makeup of that segment of the population qualified for careers in science and engineering?

5. This question has been the subject of formal study only in recent years. The first such study was made by the Office of Scientific Personnel of the Academy-Research Council about 1947 under a small grant from the Rockefeller Foundation. Somewhat later a much broadened study, under a substantial grant from the same source, was carried on under the direction of Dr. Dael Wolfle, with additional sponsorship by the other three research councils [1] constituting the Con-

[1] The American Council on Education, the Social Science Research Council, and the American Council of Learned Societies.

ference Board of Associated Research Councils. The result was a landmark report entitled, "America's Resources of Specialized Talent."

With the advent of the National Science Foundation, a source of support and a center of interest and responsibility for manpower studies was established as a part of the Foundation structure. The focus of such responsibility in the Foundation is the Office of Economic and Manpower Studies. Through this Office, the Foundation has funded a number of projects aimed at providing basic statistical information on the scientific and engineering manpower pool, its characteristics, its magnitude, its growth, and its utilization.

The Foundation has recently combined two series of publications, Reviews of Data on Research and Development, and the Scientific Manpower Bulletin into a new series entitled "Reviews of Data on Science Resources," which provides the most recent data in a concise form and on a continuing basis.

One of the responsibilities of the Foundation is the maintenance of the National Register for Scientific and Technical Personnel. This register, administered in cooperation with the appropriate professional societies, is an invaluable source of information about our scientific and engineering manpower resources.

It is of interest to note that the Carnegie Foundation and the Russell Sage Foundation are providing support for the establishment of a new Commission on Human Resources which will have as one of its main purposes the further exploration of such questions as the potential supply of scientists and engineers, their intellectual attributes, and their motivation toward careers in science and engineering.

6. What studies are the Academy or NSF sponsoring to provide more information about the nature and rate of obsolescence for scientists and engineering personnel, and about effective countermeasures?

6. It is probably true that the gravity of this problem is increasing at a greater rate than are the efforts to analyze and alleviate it.

One of the more specific considerations of the problem in a formal way was carried out by a Committee on Utilization of Scientific and Engineering Manpower established by the National Academy of Sciences under a grant from the Ford Foundation. This committee, composed of distinguished persons from industry and the academic world, explored the state of knowledge relating to this question and initiated such inquiries as were possible in view of its resources and timespan. The concluding report,[1] published last year, is a mature review of the problem with a number of significant recommendations for action. Among other non-Government groups deeply interested in this problem are the Engineers Joint Council and the American Society for Engineering Education.

The National Science Foundation is certainly aware of the need for a better understanding of the problem of scientific and technological obsolescence. This is evidenced by their recent support of an exploratory study at Case Institute of Technology which has led the Foundation to consider a full-scale study of this important problem.

It is of interest to note that one conspicuous geographical focus for this problem is in southern California where the earlier concentration of aerospace activities and the recent slowdowns in these industries

[1] "Toward Better Utilization of Scientific and Engineering Talent: A Program for Action."

has created pools of unemployment. To meet this situation there has been formed, through concerted efforts of industry, the universities, and public offices, a nonprofit corporation, Industry Diversification Institute, which is planning an action program including analysis of the extent and nature of the problem regionally, experimentation and retraining, and assistance in the reabsorption of those displaced back into the labor force.

Within the purview of the National Academy of Sciences perhaps the closest attention to the problem of obsolescence for scientists and engineers will be through scrutiny by the new Commission on Human Resources, referred to above in connection with the response to question 5.

7. Your testimony stressed collaboration in international scientific programs. Should the Foundation assume a more active role in the support of international projects? What do you regard as NSF's proper role regarding initiation, coordination, and funding of international programs in relation to the activities of (a) the State Department, (b) the Federal Council for Science and Technology, (c) the Office of Science and Technology, and (d) the National Academy of Sciences?

7. The Foundation should assume an active role in the support of international scientific projects whenever they relate to basic science and clearly are in the interests of both the evolution of science and the national welfare. The planning and initiation of new scientific programs are complex matters requiring inputs from many sources, both professional and legislative. The National Science Foundation has played a very important role in the process of initating programs in the past; it should continue in this role along the lines it has developed. There will be cases in which the Science Foundation will naturally be the initiator of international scientific programs. Usually it will want and need help from other organizations, such as the State Department, the Federal Council for Science and Technology, and the Office of Science and Technology, which are closely coupled to the Science Foundation as part of the executive structure of the Government and which have a special interest in international science programs. The National Academy of Sciences-National Research Council, being a private organization with a Federal charter, can frequently serve a uniquely valuable purpose by providing advice, either to the Science Foundation or to another agency concerned with such programs. It is my opinion that any given program will be enriched significantly by drawing on a composite of advice provided by all qualified groups that can give it. I believe that the International Geophysical Year was far more successful, because of the close cooperation between the Foundation and the Academy-Research Council, than it would have been if either had attempted to develop the program alone. In brief, I believe the National Science Foundation could and should remain in a position of significant leadership in international programs, but that such programs will benefit if the Foundation seeks companion advice and participation from other organizations, including the Academy.

8. What specific suggestions does the Academy have for the expansion of NSF's role in terms of (a) new fields of science, (b) timetables, (c) organizational changes?

8. At the present time the National Academy of Sciences is carrying through a series of studies of the various fields of science in an attempt to establish priorities within each field that will be of help to the Federal agencies in the planning of future programs. As mentioned in my testimony, these studies are under the guidance of the Academy's Committee on Science and Public Policy, and are funded in part by the National Science Foundation, which has expressed deep interest in the results. It is the opinion of the Council of the Academy that such studies should provide one of the significant inputs bearing on decisions concerning new fields of science, timetables, and possible organizational changes on a national basis. I cannot stress too strongly that the final decisions on all these matters should involve inputs from a number of sources in keeping with our national traditions regarding open discussion.

9. Is there any significance to the fact that the National Academy of Sciences is involved in every one of the Foundation's "national research programs," either as the originator of the program or as a major program coordinator?

9. For somewhat over a century the National Academy of Sciences has drawn on the best available scientific and engineering talent in the Nation to render advice to the Government. In view of this fact it is not surprising that the "national research programs" of the National Science Foundation should involve some significant input from the Academy-Research Council. As I have said earlier, the Academy is engaged in continuing efforts to assist Federal agencies in the planning of their programs. The agencies, I believe, have benefited substantially from such help, in large part because of the experience the Academy has developed in bringing highly qualified professionals together for free and frank discussion of the merits and demerits of various programs, both new and continuing.

10. Are too many Federal agencies today involved in supporting basic science grants and science education? Is there duplication here? Might not the Foundation assume a more central, if not exclusive, role in this regard? Who coordinates this area?

10. Every Federal agency has need for access both to the products of basic science and to the individuals who participate in basic science. Moreover, all agencies have need for qualified personnel trained at advanced levels in science and engineering. I believe it is essential that all the major agencies retain programs that support basic science and related educational activities. This should be looked upon as both normal and healthy. Thus far I have seen no evidence in the period since 1945 of any significant duplication of effort that could be called wasteful. In part, this is a result of the fact that the various agencies maintain both formal and informal links with one another so that each agency is well aware of the support programs of others. Indeed, the existence of support by several agencies provides a pattern of checks and balances that helps to maintain quality in all.

Clearly the National Science Foundation should play a major role in coordinating programs. In the present framework, however, the Federal Council on Science and Technology has assumed the role of a central coordinating body or council among the various executive agencies, including the Science Foundation, which regard themselves as

essentially equal. Taken as a whole, I would not recommend any radical change from the present pattern.

11. In your judgment, should the scientific disciplines have more representation in our legislative bodies?

11. While it is desirable that some legislators should have professional training in either science or engineering to guarantee that the point of view of the professional scientist and engineer will have some direct representation when legislative decisions are made, legislators for the most part will act responsibly, no matter what their professional experience. Legislators can always obtain professional viewpoints directly from scientists or engineers who are not legislators. What is most important, of course, is that they know how to weigh such views and relate them to the national interests.

12. Users of scientific information seem to be confused as to what Federal resources are currently available to them. Would the National Science Information System be more effective if the numerous and varied existing Federal scientific information centers were consolidated in one location?

12. Each Federal agency will automatically be the source of some type of scientific information. The National Institutes of Health will be a source of information in the medical-biological field; the Atomic Energy Commission will be a source of information related to atomic and nuclear science and technology. I am inclined to believe that it is essential to have each agency maintain those centers of information that are closely related to their missions. As in the matter of support of scientific research, the important thing is to have significant coordination between the information centers. Thus, requests from outside directed toward one center may be referred to another if the relevant information is more readily available in the other. The National Science Foundation could well provide a major coordinating service within the executive side of the Government. Indeed, it might be desirable if the National Science Foundation had one or more centers to which inquiries could be directed. I believe, however, that it would be a mistake if such a center had rigid monopolistic control over the dissemination of information. The resultant center would probably have a monolithic quality that would guarantee that it would be relatively ineffective. We do not expect the Congressional Library to be the only repository for books in the country. There is no more reason for having only one information center.

13. How does the Academy reconcile its serving in an advisory capacity to the individual Government agencies and to the President?

13. Whenever the National Academy of Sciences-National Research Council is called upon to render advice to any branch or agency of the Federal Government, a committee of qualified experts is chosen to provide the advisory service. In each case, the committee is furnished with what might be termed the charter associated with the special request, and is asked to follow rules and procedures of conduct in its study that tend to assure objectivity in arriving at conclusions and recommendations. In many instances, individuals who are unusually well qualified serve on two or more of our advisory committees. As I remarked earlier in this series of questions such persons usually are a great asset to the committees on which they serve because of the breadth of their experience and the depth and range of their points of

view. Every effort is made to guarantee sufficient diversity of participation in each advisory committee to minimize the likelihood that any given committee can be dominated by any special interest or interest group. An agency or office that calls on the Academy-Research Council for advice is protected by the fact that the Council of the Academy is exceedingly conscious of the dangers that could arise if any of our committees became strongly biased.

14. What was the role of the National Academy of Sciences in the origin of Project Mohole? What role, if any, does the Academy play today?

14. The Mohole proposal to drill through the earth's crust to the mantle was first made in 1957 by an independent group of earth scientists and engineers gathered under the auspices of what they chose to call the American Miscellaneous Society, or Amsoc, an informal society having no legal or administrative structure. A number of the members of the group were also members of the National Academy of Sciences. They soon became convinced that the project had practical promise, and asked the Academy to assume responsibility for furthering it and for seeking the support of the National Science Foundation. At the end of 1957, the Academy constituted the group as a Committee on the Mohole Project, within the Academy-Research Council structure. This Committee was generally known as the Amsoc Committee.

With the support of the National Science Foundation, and under the guidance of the Amsoc Committee of the Academy in matters of scientific objectives, site selection, drilling techniques, and ship design preparations were made for the first experimental drilling. This was to determine the feasibility of drilling at the bottom of the deep ocean from a free-floating vessel positioned by constant maneuvering with reference to anchored buoys in the open sea. This experimental drilling was carried out with great success off the coast of lower California in the spring of 1961 under the direct supervision of the Amsoc Committee's technical staff. The full report of the drilling is contained in the Academy's report, "Experimental Drilling in Deep Water at La Jolla and Guadalupe Sites," No. 914, dated 1961.

With the end of this experimental phase, the Council of the Academy decided that for the much more extensive next phase, involving the attempt to drill the Mohole itself, the Academy should revert to its traditional role of acting purely in an advisory capacity dealing primarily with scientific questions and objectives, rather than assuming the operational responsibility for a large and complex hardware program. The National Science Foundation therefore set about the task of finding a suitable contractor to carry out the major phase of the project, with the Amsoc Committee of the Academy remaining available for advice. In January 1964, the Amsoc Committee recommended, and the Academy agreed, that the Committee should be disbanded in favor of individual advisory panels on the selection of drilling sites and on scientific objectives. These panels have worked closely in these matters with the personnel of the National Science Foundation and its Mohole contractor.

Response by Dr. Alan T. Waterman, Former Director, National Science Foundation, to Questions of the Subcommittee on Science, Research, and Development

---

1. What was the immediate effect of Reorganization Plan No. 2 on National Science Foundation operations?

1. The major effects were:

(*a*) Freedom from responsibility for evaluation of other Federal agency programs as such, thus clarifying a difficulty outlined in my testimony before the Subcommittee on Science, Research, and Development, June 30, 1965.

(*b*) The Director of NSF became a voting member of the National Science Board, ex officio, instead of a nonvoting members.

(*c*) The Director became Chairman of the Executive Committee of the National Science Board, thus strengthening his position with respect to the Board. This provided readier opportunity for the Director to obtain discussion and consultation by the Executive Committee on minor matters or matters for preliminary discussion by the entire Board.

Reorganization Plan No. 2 did not remove from the NSF its authority for developing national science policy. In this respect it merely specified that the Office of Science and Technology have authority to employ such aspects of NSF authorization as needed for purposes of policy determination.

2. Please outline the respective roles of NSF, the National Science Board, the Office of Science and Technology, the President's Science Advisory Committee, the National Academy of Sciences, and the White House in the making of science policy? Where did initiatives arise? Can you give examples?

2. My understanding of the respective roles of these bodies may be summarized as follows:

(*a*) As outlined in its act, the NSF has fundamental responsibility for the support of basic research and education in the sciences (including mathematics, engineering, and social sciences). Among the detailed programs of the NSF for carrying out this mission are the following: Policy planning for basic research centers and facilities, international science activities, research and policy formation on science information matters, research and manpower studies, graduate and postgraduate fellowships and training, improvement of science teaching and science course content, special projects for undergraduate teaching and research, institutional development, and public understanding of science.

The NSF is the focal point in the Government for the initiation of comprehensive programs in basic research for special areas of science and for the receipt of studies and recommendations from the National Academy of Sciences-National Research Council or other scientific

organizations on national and international programs in particular scientific disciplines. For example, it is the Federal agency responsible for the supervision and funding of international basic scientific enterprises such as the International Indian Ocean Expedition, the International Year of the Quiet Sun, and the Antarctic Research Program (the logistic support of the last is the responsibility of the Department of Defense—Navy Department). By amendment to its act it has also been assigned specific responsibility for research on weather modification. By amendment to its act and by Executive order the NSF has increased responsibility for research, studies, and coordination on scientific information matters.

(*b*) The National Science Board has overall policy responsibility for the National Science Foundation and also exercises supervision and control over specific components of the Foundation's programs as stated in its act, notably the approval of fellowships and research grants. By amendment to the National Science Foundation Act these two detailed responsibilities may be delegated by the Board to its Executive Committee or to the Director. Following passage of this amendment the Board delegated this authority to the Director, subject to designated ceilings above which approval of the Board is necessary.

A most important role of the Board is to determine and recommend national policy for the support of basic research and related matters. Among examples have been the following: the assignment of authority and encouragement for the conduct and support of basic research among other Federal agencies, U.S. support of important international science programs, Federal establishment, and support of centers for basic research, loyalty considerations in the case of Federal fellowships in science and the introduction of programs and procedures which set precedents in support of scientific research and education. This authority of the Board may not be delegated to the Director or the Executive Committee.

(*c*) The Office of Science and Technology, established in 1962 by reorganization plan, has the responsibility for reviewing, evaluating and coordinating R. & D. programs conducted by Federal agencies, policy planning for research, making studies of science matters concerning R. & D., and for the financing and administration of such committees as PSAC, FCST, and their panels. It provides for the first time a statutory office in the Offices of the President for these purposes and is also available to the Congress. (Authority for policy planning in science is still retained by the National Science Foundation with special reference to basic research matters.) Its Director is appointed by the President and thus far has been also the special assistant to the President for science and technology.

(*d*) The President's Science Advisory Committee, established by Executive order in 1958 in the Office of the President, is the successor to the Science Advisory Committee established by Executive order in 1950 (administratively under the ODM). It is a part-time Committee appointed by the President to advise him on scientific matters either at his request or on its own initiative. Its Chairman is elected by the Committee and has always been the same individual as the special assistant to the President for science and technology, for which the first appointment was made late in 1957. Its chief functions at the White House level are to consider, review, or study topics, projects,

or programs concerned with R. & D., scientific education and manpower, science information, international science affairs, or other related topics. These are frequently performed by panels set up for the purpose and result in reports, some of which are published.

(*e*) The National Academy of Sciences has the statutory responsibility of providing advisory and consulting services, when asked, for the President, the Federal agencies or the Congress. The NAS was established by act of Congress in 1863 and the act was extended in 1916 to include the National Research Council which provided for the formation of standing and temporary divisions, committees, and panels to assist the NAS in this function. The NAS–NRC is officially regarded as a quasi-Government organization since it has responsibility to the Government but receives no funds in the President's budget. In carrying out its operations under Government request, financing is provided by the component or agency which makes the request. It is, of course, a nonprofit organization.

The NAS is the highest authority on science in the country. Its members are elected from among the scientific community and include a limited number of foreign scientists. In addition to its Government relationships, the National Academy of Sciences has comprehensive programs carried out under its own initiative for the study and planning of research. It holds periodic meetings which include research papers delivered by its members.

In addition, it is the adhering body for the United States in international nongovernmental enterprises such as the International Council of Scientific Unions and its component committees.

(*f*) The role of the White House in the making of science policy may be initiated officially by request of the President, by the Director of the Office of Science and Technology, or by the PSAC in the transmission of recommendations via the Special Assistant for Science and Technology, by the National Science Board via the NSF Director, and also on special matters in response to agency request. At the present time coordination is the responsibility of the Director of the Office of Science and Technology, who is simultaneously special assistant to the President for science and technology, Chairman of the PSAC, and Chairman of the Federal Council for Science and Technology.

Science policy may of course be promulgated in many ways—by presidential announcement, by Executive order, or by presidential endorsement of recommendations by PSAC, FCST, OST, or NSB.

3. What problems are foreseen arising from the domination of mission-oriented research over "free" research?

3. (My discussion of this topic concerned basic research only; presumably applied research supported by an agency is always mission-related.) Chief problems arising from this cause are: limitation of basic research to scientific areas which are judged in advance to underlie developments of existing or potential practical usefulness; e.g., military defense, health, power, agriculture, communications, etc. Generally speaking, mission-related basic research is the variety supported and conducted by industrial research departments and by Government R. & D. laboratories, where the overall purpose is to improve existing products and techniques or to initiate promising useful new ones. This, of course, is an essential part of technology, and

should continue. Obviously it is limited to fields of predicted promise of utility.

As outlined in my address before the American Association for the Advancement of Science,[1] on an approximate basis about 80 percent of the basic research in the country may be regarded as "mission-related" and only 20 percent "free." Hence, mission-related basic research predominates in support by a ration of 4 to 1. The question is one of determining the optimum proportion between the two. One can hardly expect to give the answer in quantitative terms, since there is no ready measure of importance of the results of either except in isolated cases, and in the case of free research the significance of the findings may not be evident for many years.

There is and always will be a strong demand for research, both basic and applied, which is expected to solve important practical problems and to explore regions which may be identified as holding promise for development. No one can quarrel with this thesis. Indeed, many scientists and engineers have in recent years called attention to the great need for this type of activity and there are some who have criticized university research as being too predominantly academic; i.e., "free." This criticism probably stems from the fact that both kinds of research have been increasingly handicapped for lack of funds and with mission-related research, as usual, having an apparent immediate urgency. In my opinion the remedy for this is to review existing developmental projects more critically, to invest in them with more care and thoroughness and in this way to release funds for purposes of research. It is in development where about 70 percent of the R. & D. money is spent. Furthermore, the techniques for this examination and review have been greatly improved by the use of computer facilities, systems analysis, and operations research. Above all, whenever possible, the adoption of crash programs should be avoided as being relatively inefficient and most extravagant in cost.

The chief arguments for free basic research are simple in principle. They are:

(*a*) Mission-related basic research by definition aims at foreseen goals. Free basic research, not having this limitation, offers more opportunity for important and novel discoveries. This asset is borne out by history, since the capital innovative discoveries have generally been made by individuals working on this basis, as witness electromagnetic induction, electromagnetic radio waves, the electron and the laws of electronics, X-rays, radioactivity, relativity, antibiotics, and the laws of evolution. If one tries to argue that the modern situation is different, one should recall the statement made by a leading physicist and believed by many, just before the turn of the century, that the major laws governing the physical world had all been discovered and it remained only to work out the details. As a fitting rejoinder there shortly followed the discovery of X-rays and radioactivity. It is a dangerous thesis to assert that no further capital discoveries can or will be made, and the most likely source is free basic research.

(*b*) The cultivation of free basic research establishes a continually expanding accumulation of basic data on a very wide front, which then becomes available, whenever the need arises, for use in develop-

[1] "The Changing Environment of Science," Science, pp. 13–18, Jan. 1, 1965, vol. 147, No. 3653.

ment and in applied as well as further basic research. This storehouse of available information often obviates the need for new basic or applied research undertaken on a crash basis in developmental projects to remove bottlenecks.

(*c*) Advanced academic training in basic research provides specialists available for future fields of hitherto unforeseen importance.

(*d*) The performance of free basic research is a most important ingredient in the progress of human thought and culture.

It should be added that the encouragement and support of free basic research encounter most fertile soil for its cultivation in the free world and particularly in the United States. In countries with rigidly planned economies this is severely limited if not almost unknown. While in the short haul there is great power in research toward the achievement of foreseen objectives, in the long run limitation to such goals tends to proliferate unwarranted detail, and results in major blind spots as world science progresses into unforeseen territory. The thesis of the undersigned is that the United States is in an advantageous position to make substantial progress in both mission-related and free research.

It is difficult to formulate criteria for the optimum balance between mission-related and free basic research. Insofar as the NSF is concerned, an opinion can be expressed on the optimum extent of support of the free variety. Thus, in the NSF basic research program over the years the proportion of basic research funds granted to applicants has usually varied between 25 and 30 percent of the total funds requested. In view of the quality of the proposals received a more justifiable proportion would appear to be 50 percent. Otherwise the program is spread too thin and too many good projects may go without support. A 50-percent proportion should allow for the requisite selectivity to guard against backing mediocre work.

If the research budget of the NSF could be increased so as to raise its basic research to such a level it would also serve to place the NSF research program in better balance with the basic research funds provided by other agencies. As an approximate estimate, if the basic research money to the NSF were to be increased so as to fund 50 percent of the total amount requested by applicants, then the NSF would be able to furnish about 40 percent of the Federal support of basic research to academic institutions or double its present fraction, without reducing the funds in support of mission-related research.

4. Should the National Science Foundation Act be revised to permit more operational and/or applied research support? (Note that this says "permit" and not "require.")

4. While in principle it might seem a good idea to revise the National Science Foundation Act to permit more operational and/or applied research support and thereby give the National Science Foundation more authority, I do not believe this would be wise unless and until a pressing case arises where this is badly needed. The reason is that, if such authority were permitted, the National Science Foundation would probably be under constant pressure from one direction or another (including from within) to use this power. Direct operational control would tend to develop bureaucratic characteristics, which the National Science Foundation should strictly avoid. Besides, a general entry into applied research would in the long run tend to

bring about relative neglect of the Foundation for basic research. It would change the clientele markedly by bringing in industrial firms and thus expose the NSF to quite strong pressures and to selective support of profitmaking institutions. The present unique position of the NSF in upholding basic research is a strong asset in our Government and among the scientific community. Applied research should be the concern of those Federal agencies which have more specific missions. Furthermore, this division of responsibility encourages the NSF to maintain closer contracts with other agencies for their mutual benefit. It also reduces the area of undesirable competition.

I should favor making no general revision of the National Science Foundation Act to provide this general authority but, if circumstances warrant, assigning special authority to the NSF for a particular, urgent use where no existing agency has authority or competence.

5. How can the National Science Board be made more effective? Should its role be changed? Is new legislation needed?

5. In its present form the National Science Board has the advantage of wide and complete coverage of the scientific interests of the country with respect to geography, scientific disciplines, type of institution and administrative experience. This is possible by the size of the Board and its manner of selection. Administratively it is a large Board for effectiveness in deliberation and disposal of its affairs. This could be remedied by reducing the number, say, to a Board of 15 or 16 members. However, this would limit the aforesaid advantage of representation. A more desirable alternative would be for the Board to delegate more of its authority to its Executive Committee, and its planning to subcommittees or panels of the Broad. The latter alternative is being used more and more. As the size and complexity of the Foundation's operations grow it seems inevitable that the Board should delegate more and more functions to its Executive Committee and/or the Director.

It is here that I believe a change in the National Science Foundation Act might be considered, since the act limits the authority of the Executive Committee.

It should be added that this subject has on several occasions been discussed by the Board. The outcome has always been that its members feel they should all be involved in final determinations essential to policy.

6. Does the fact that members of the National Science Board hold concurrent membership in other Federal bodies providing advice on science policy matters compromise or otherwise influence their independence?

6. Concurrent membership on other Federal bodies is not a serious problem provided membership in other bodies is only on a similar part-time basis and limited to advisory services. It is an asset, in my opinion, to include some overlapping membership of this kind, both in providing broader background for deliberation and in forestalling duplicative discussion or troublesome policy disagreements with another agency. Besides, a strict limitation to independent membership can cause severe restrictions in selection of available members, to the detriment of quality. The latter is a far greater handicap to the effectivenes of such a Board.

7. When the NSF was created in 1950 with a budget limited to $15 million, the National Science Board could, presumably, exercise close supervision over the workings of the Foundation. Since then the budget of the Foundation has increased to about $480 million and the Board has delegated much of its authority to the Director, keeping for itself the authority for major policy decisions. In effect, then, the Board serves as a sort of Board of Governors, and is the only such nonregulatory agency with this form of dual (Board and directory) authority and responsibility. The question arises, is it in the best interest of the country and of science in general to maintain this dual authority; or would it perhaps be better to have the Director solely responsible for the operation of the Foundation, and have the Board serve in an advisory capacity to the Director (a National Science Advisory Board)? In the light of your experience with NSF growth, your comments on the problem are requested.

7. The dual authority existing in the NSF appears to be an outgrowth of the first National Science Foundation Act passed by the Congress which was vetoed by President Truman. That version followed the pattern of the old NACA whose members were appointed by the President and constituted a "governing board" which then selected the Director and the latter reported to them. The President's veto at that time was caused by his belief that this would place the disposal of Federal funds in the hands of a part-time board which would constitute insufficient governmental control. The National Science Foundation Act of 1950 modified this so that the Director was appointed by the President and officially reported to him, while the act limited the authority of the Director in carrying out certain programs without the Board approval. The policy-forming role was retained by the Board. Following Reorganization Plan No. 2, however, the roles of the Board and the Director were more fully coordinated by making the Director a voting member of the Board, instead of a nonvoting member, and by making him Chairman of the Board's Executive Committee.

In the operations of the Foundation this somewhat unprecedented situation has worked well. Conceivably a stalemate could develop or one in which the Board took a determined position contrary to the wishes of the President. The Director would then be in duty bound to back the President's point of view or resign. During my administration no such situation came close to developing. This subject was carefully considered by the Board after a decade of experience and the conclusion reached that the existing setup had worked well and required no change.

Cases calling for prompt action between regular Board meetings may be handled by (*a*) calling special Board meetings (2 weeks' notice) or (*b*) Board delegation of authority to (1) Executive Committee (now in force) (2) the Director. However, under the present act, policy authority cannot be so delegated.

The present arrangement constitutes a safeguard against undue Federal domination or control over scientific activities and enterprises throughout the country. There is at present no body dealing with scientific matters in the executive branch which has comparable experience, stature, and representation, on Government-university relationships, for example. Therefore, in my opinion it is worth continu-

ing as long as no serious difficulty arises. The current arrangement is probably an asset in maintaining good public relations with the scientific community.

If the Board were to be relegated solely to a role advisory to the Director, this would of course strengthen his hand but by demoting the authority of the Board, it would also make membership on the Board less attractive and tend to render the members less attentive to their Federal responsibilities. In my experience with bodies having advisory or responsible functions, a board with assigned responsibility exercises more care and thoroughness in its deliberations and its actions.

8. Please explain in more detail the recommendation in your testimony that NSF should have a contingency fund to exploit breakthroughs in basic research.

(a) Why is a contingency fund needed if scientists are already supported?

(b) Cannot funds be reprogramed?

(c) Are not scientists given enough flexibility in grants to exploit breakthroughs?

8. As partially explained in my testimony a contingency fund for NSF is desirable in order to provide immediate support for a new and promising research discovery or a novel and effective technique of research. As it is, budget plans are made about 2 years in advance of receipt of the corresponding appropriation. These plans are based on the estimated cost of ongoing research, assumed to continue at about the current level, plus the estimated amount required to initiate support of new proposals. Consequently, if during a particular budget year an impressive finding is made which indicates need for extension, there is no money available for the purpose without curtailing funds already planned. This extension may take the form of increasing the staff and equipment already on the project, providing a special research installation for the purpose, or making a series of grants to a number of other research investigators to take up research in the new area. Often this situation is aggravated by the final appropriation being less than the budget requested.

In answer to questions (*a*), (*b*), and (*c*):

(*a*) Contingency funds are needed even though scientists are already supported, since to do justice to important new findings additional funds are required over and above those already provided.

(*b*) Reprograming would mean taking funds from and thus handicapping either ongoing research or new projects of excellent quality or both. Due to the lag in the budget cycle a certain amount of reprograming is always done, of course, but it cannot at present cover the prompt cultivation of unexpected and highly important new discoveries.

(*c*) Scientists are indeed given flexibility in grants to change the character or aim of their research in the light of their findings, upon keeping the NSF informed, but this does not provide additional funds when needed, nor does it permit exploration by others when that appears desirable.

9. Why should not more support be given to nonprofit organizations which are doing anywhere from 20 to 40 percent of their research in fields that are basic?

9. Nonprofit organizations doing basic research may and do apply to NSF for support along with academic institutions. If their proposals stand up successfully in competition they receive grants. This policy is believed to be sound. On the one hand one should bear in mind that such organizations are not ordinarily concerned with education and training, which may be an important consideration in a particular research project. On the other, quite often such an organization may have excellent prospects for full-time team research involving the association of a number of research specialists.

10. We have heard criticism that there has been a tendency, in order to spread research around, to underfund good projects. Do you concur with this point of view?

10. There undoubtedly is a tendency to underfund good projects. In my experience the quality of research proposals coming to the NSF is such that about 50 percent of the total of all funds requested should be granted. This allows a fair margin of selectivity for competitive purposes and to insure quality. Those selected should be financed adequately. But when the above figure is as low as 25 to 30 percent, which has been customary, then a program director is strongly tempted to increase the number of grants by reducing the amount requested by each. If this becomes common knowledge among the grantees, then a quite natural response is to try to anticipate this damaging reduction by increasing the amount requested. When the agency notes this, a most unfortunate situation has developed, destroying confidence on both sides, to the detriment of efficiency and good public relations.

11. We also have heard complaints that NSF has exhibited a tendency to overcontrol its grants through excessive reports and other redtape. Is this a serious problem?

11. The tendency to overcontrol grants through excess reports and other redtape is one which a Federal agency always has to watch, especially in dealing with basic research in academic institutions. This constitutes something of a dilemma since one would wish a basic research scientist to be as free from intereference as possible in his work, while at the same time insuring that necessary regulations are met and that pertinent information is available whenever questions or criticisms may arise. The aim of NSF has been to try to keep the financial and administrative arrangements and reporting within the administrative office of the grantee institution, thus giving the research scientists maximum opportunity for concentrating on their research. Most academic institutions, especially those with graduate schools, have set up administrative offices and thus help to further this procedure. As a rule the responsibility of the research scientist to the NSF is to keep the latter informed about unusual progress or change of aim and to furnish a research report at the conclusion of the grant together with copies of any research papers as they appear. Actually the time of the research scientist in administrative matters is much more likely to be taken up with their local administrators than with the NSF.

Progressive steps have been taken in recent years to simplify accounts and recordkeeping at academic institutions by arranging unified accounts covering for a given institution the existing research grants.

The problem may easily become serious if not closely watched by both parties. As a rule most setbacks in this respect occur as a result of complaints or criticisms which require an investigation and which, rightly or wrongly, result in additional regulations.

12. What conditions have developed in recent years that warrant changes in emphasis as well as expansion of NSF programs?

12. Conditions that have developed in recent years which warrant changes in emphasis as well as expansion of NSF programs are as follows:

The success and continued growth of the so-called project system of research support at academic institutions has led to the initiation of programs designed to compensate for certain difficulties it may cause, especially at universities receiving extensive Federal research support. In the project system, grants or contracts are awarded to an institution for research projects selected by the agency. In the case of NSF and several other agencies this selection is commonly made from among proposals received from individuals or teams of scientists, with the endorsement of their institutions. The selection in a given scientific field is usually made with the advice of experts in that field. In this way the agency and the scientific community cooperate in establishing the support program. Its assets are: best possible guarantee of quality of promise and performance among applicants for support; close cooperative planning between the Federal agency and the scientific community; excellent public relations with the scientists and their organizations. However, since supported projects are selected and financed from outside the institution, project system may bring about the following difficulties for academic institutions which receive considerable support by this method: lack of consideration for the institution itself; lack of flexibility and independence for planning by department and institution heads; possible lack of control on the part of institutional authorities; possible conflict of interest on the part of scientists between a supporting agency and their own university administration.

In the case of agencies with practical missions the project system is justified on the ground that they are primarily interested in research results, and therefore should select for support research relevant to their missions in the most competent hands available, wherever these may be found.

In the case of the NSF, however, consideration may and should be given to the effect of the research support upon the health, strength, and promise of the institution. Accordingly the NSF has established the following programs designed to compensate for these difficulties: institutional base grants; institutional science buildings and research facilities; science development grants.

In its graduate fellowship program, because of preponderant choice by fellows of a few outstanding universities, the NSF has established a supplemental, cooperative fellowship program in which the institution recommends a limited number of fellowship appointments, the awardees to attend the institution, and a training grant program whereby the institution receives funds for graduate research training in a particular area of science.

13. Do you agree with statements of some authors in the recent NAS report on "Basic Research and National Goals" that there is a "deep financial crisis" in the physical sciences?

13. Yes, unquestionably.

That this situation has been cumulative for many years may be observed by noting that the appropriations for NIH (mission-related research) have commonly been higher than those requested in the President's budget, whereas the appropriations for NSF (free basic research in physical and life sciences) have inevitably been less. Correspondingly, the proportion of funds granted to funds requested by applicants has been considerably lower in NSF than NIH. Add to this the fact that in recent years the mission-related agencies which chiefly support the physical sciences, except for NASA, have had gradually to reduce their support of research and the NSF has not had the funds to compensate for this loss of support.

This deficiency in support of the physical sciences became accentuated in fiscal year 1964 when the NSF received and appropriation of only $345 million as compared with $589 million in the President's budget request.

14. The Foundation in recent years has devoted some funds toward improving science teaching as well as curriculum in undergraduate as well as high school levels. Based on this experience, do you believe that fellowship or institutional support of pregraduate education should be proportionately increased or decreased?

14. As to increase or decrease of fellowship or institutional support of pregraduate education, it is my view that the NSF should continue its policy of not establishing undergraduate scholarships (NSF has used this term rather than "fellowships," which is reserved for graduate students and beyond), in the belief that individual undergraduate support is best left as a responsibility of the institution.

General institutional support of pregraduate education would seem more properly to be a responsibility of the U.S. Office of Education in cooperation with State or local organizations rather than of the NSF. In the case of elementary and secondary education, the NSF can provide, as in the past, a most useful service in experimental and pioneering studies and programs directed toward the improvement of science learning and teacher training. If and when successful, the results may be incorporated into the regular educational programs of the Office of Education.

15. What is the explanation for the NSF report in which a shortage of scientists and engineers was projected under the next 10 years, in contrast to the Killian report released about the same time that cited no across-the-board shortage?

15. There have been two NSF reports regarding the projected shortage of scientists and engineers. The first [1] pointed out a current trend which would provide an adequate number by 1970 but only if properly planned and financed. It also reported that not enough scientists and engineers were taking up positions at academic institutions to provide the necessary teaching. The second [2] examined the trend in employment of scientists and engineers with a projection for the next decade. Both based their discussion and conclusions upon a report by the

[1] "Investing in Scientific Progress," 1961.
[2] "Profiles of Manpower in Science and Technology," 1963.

Bureau of Labor Statistics [3] sponsored by the NSF. It is my recollection that the two were in reasonably good agreement; namely, that under adequate planning and financing an adequate number would be trained and employed. Both warned of present serious shortcomings in planning and in funding. A PSAC [4] report was more pessimistic and indicated that we would fall short of training the desired number of engineers and physical scientists.

The Killian report made thorough examination of the utilization of scientists, engineers, and technicians. It concluded that on the whole conditions were healthy in these respects and that indications were that they would continue so.

Except for the PSAC report, there would seem to be reasonable agreement among the three others. All agree, however, that it is of the greatest urgency to provide money, facilities, and trained personnel to do this job, especially since we are already badly in arreas on this point.

16. Are the NSF institutional grants consistent in policy and content with those of National Institutes of Health, NASA, and other Federal agencies? What is the amount of private sector support in these same programs?

16. There are several kinds of NSF grants which may be regarded as institutional. They are as follows:

(*a*) Institutional base grants, which consist of an annual lump sum to the head of the institution amounting to a certain percent, on a sliding scale, of the total NSF research grants made to the institution during the previous year. These grants may be freely used for any scientific purposes; no advance listing is required.

(*b*) Facilities grants, covering on a matching basis (50 percent) construction of laboratory buildings and provision for research installation and equipment.

(*c*) Science development grants, in response to comprehensive proposals from the institution, to defray the costs of research and/or teaching activities according to well-developed plans. This is a highly selective program at present, since it has only been financed in a modest way, beginning about 2 years ago.

(*d*) Training grants are also made to institutions but these generally cover training only in a specific scientific field, at the graduate level.

The institutional grants made by NIH are somewhat similar but originally at least included certain limitations in content and administration not present in the NSF variety. The two programs by NSF and NIH were started at about the same time and were fully discussed policywise between the two agencies.

NASA has a more independent program of institutional grants although it was discussed with NSF before initiation. Its intent was to establish research and training programs at educational institutions concerned with space activities in science and related subjects. These projects were activated upon successful outcome of negotiations with key institutions in different parts of the country, and are subject to possible modification in the light of experience.

[3] "Scientists, Engineers, and Technicians in the 1960's."

[4] "Meeting Manpower Needs in Science and Technology, No. 1: Graduate Training in Engineering, Mathematics, and the Physical Sciences," the White House, 1962.

In one important instance the Advanced Research Projects Agency has initiated a program of institutional contracts for research on materials. They are liberally financed and likewise were initiated following negotiations with key institutions having high competence in the physical science fields relating to materials and engineering.

The AEC contracts with academic institutions for comprehensive programs relating to atomic energy are well known.

Federal policy and content in these various programs have been discussed by the respective agencies with NSF during the early stages of their development. During the stages of putting plans into operation the coordination has been closest between NIH and NSF, who have had a long history of cooperation.

In line with the new national educational acts the Office of Education is embarking on a variety of institutional grants among educational institutions.

The amount of private sector support is best obtained from NSF.

17. What is known about the size and makeup of that part of the population which has the basic capacity to become scientists or engineers?

(a) Has there been a discernable range of quality in the students which Foundation has supported?

(b) Could more graduate students be supported without compromising quality?

(c) Is the quality cutoff point different in different fields of science and engineering?

17. The question with its subdivisions had best be answered by the NSF which has followed this subject closely over the years and should be able to give up-to-date figures.

18. How does a program achieve the status of a national research program?

18. A program in the NSF achieves the status of a national research program when it follows a unifying subject matter pattern which may be undertaken in similar manner by the participating institutions and when it has been approved by the President and the Congress as such in the NFS budget. Examples are: weather modification, Antarctic research program, International Year of the Quiet Sun.

19. What is the basic objective of the Foundation's weather modification program? Why was this program given to NSF in 1958 rather than to some other Government agency?

19. The basic objective of the Foundation's weather modification program is to stimulate and support basic research underlying the fundamental processes in nature which control such phenomena is climate, precipitation (rain, snow, or hail), thunderstorms, and violent storms such as hurricanes and tornadoes. The authorization includes following current weather modification attempts and research on the subject in other countries. Authority is also included to engage in applied research and initial development to follow up opportunities uncovered in basic research on the subject.

This program was assigned to the NSF in 1958 by amendment to its act after recommendation by the President's Committee on Weather Control, a recommendation accepted by the Director of NSF after endorsement by the interested Federal agencies. The reason

for assignment to NSF was the conclusion by the President's Committee on Weather Control that progress in weather modification awaited a fuller understanding of the natural processes involved, which could only be obtained through basic research. In carrying out this assignment it has been the stated attitude of the NSF that successful developments along the lines of weather modification should be turned over to an appropriate mission-agency such as the U.S. Weather Bureau for implementation.

20. From the standpoint of objectives, program content, and management, which of the NSF's programs do you consider to have been the best; and which the weakest? Based on your experience, what would you say are NSF's notable weaknesses or deficiencies? How may they be corrected?

20. It is difficult to attempt evaluation of NSF programs from the standpoint of objective, program content, and management. Practically all of its programs were planned carefully by the Director and his staff, studied by the Board from the standpoint of the general objective of the Foundation, the advancement of basic research, and education in the sciences, as well as by appraisal of the particular program in question. They were then approved by the President and funded by Congress.

(*a*) It is my opinion that the objectives of NSF programs have consistently been sound and so regarded. Program content has often been subject to modification in the light of experience, after some degree of experimentation—a very health procedure—and the same has occasionally been true of administrative arrangements and management. As to performance, generally speaking, the most effective thoroughly established programs of the NSF and the ones receiving widest approbation from the scientific community have been: the regular programs of grants in support of basic research by the project system; the fellowship programs for graduate students, postgraduates, and science faculty (including teachers); summer institutes for teacher improvement; and science course content studies.

(*b*) More special programs with important objectives that have filled critical research needs and have been well received are: national research centers; certain national research programs—the IGY (in cooperation with the NAS–NRC), the Antarctic research program, oceanography (in particular, provision for basic research vessels and shore bases and in the International Indian Ocean Expedition), the International Year of the Quiet Sun (with NAS–NRC cooperation); research facilities, especially for graduate research, university centers for computing, ecology and atmosphere research; periodic studies and analyses of R. & D. and scientific manpower activities, inside and outside of Government; research and development for more effiective sciense information exchange; and basic research and science manpower policy planning.

(*c*) Programs of high objective importance which have lagged concern NSF participation in basic science affairs and science education in other countries, apart from international programs. Here achievements have been limited by budget restrictions, and by difficulties underlying cooperative arrangements with responsible Federal agencies. Examples are: provision for wider extension of astronomical research facilities in the Southern Hemisphere—a critical bottleneck

for current U.S. astronomical research; NSF technical assistance in Science education among developing countries.

(*d*) On the management side, in the case of the development of a costly research project, it is not at all unusual to encounter difficulties in matching plans with reality and in making steady progress.

In the history of NSF the project receiving by far the most criticism has of course been Mohole. This project, to drill through the earth's crust and sample the mantle, was and is outstanding as to scientific objectives, daring in concept, and of a technical difficulty somewhat comparable with exploration in outer space. Criticism centered around three main aspects: Selection of the contractor; technical procedure advocated by contractor; decisionmaking and supervision of project by NSF. These criticisms were initiated by a certain few individuals who stimulated a large amount of adverse publicity. These were mistaken criticisms, as borne out in review and by further development of the project. The following lessons are to be learned from this episode: (1) When an agency such as the NSF has a special research project of this general character, approved by the President and funded by the Congress, then it must be universally recognized that the agency (NSF) has full authority for decisionmaking—this cannot be assumed by an advisory body, (2) for internal management purposes, the agency should employ a highly capable and experienced liaison officer, on location continuously available to the contractor, and a similarly qualified full-time project officer in the agency responsible for its interests and those of the Government, and for liaison with appropriate advisory committees. In the Mohole case a fully qualified engineer was employed by the NSF in the former position at the outset, but for the latter no qualified scientist was found to be available for several years. In the interim this duty fell upon a staff member who, while well qualified, had responsibility for the entire earth sciences program. This situation came about largely from the continued opposition of the Mohole Advisory Committee, in principle, to such an appointment—a failure to appreciate point (1) above. The Mohole continues to be a most important pioneering project in geology and geophysics and constitutes a real asset to the United States in international science.

(*e*) Progress in the solution of the science information problem has been slow, due to its complexity, the need to develop and find acceptance for novel methods using modern automation techniques, and to the extraordinary rate of growth of the material to be dealt with. Its solution will depend upon the successful outcome of research into the critical phases of the problem, and the evolution of an overall system in which all will cooperate. Because of the skills and experience in many private and public establishments in this activity in the United States, the best solution would appear to be to devise a system suitable for cooperation by all such, rather than to attempt to organize a single comprehensive agency for the purpose as has occasionally been suggested. For the latter the problem is too large and complicated to provide adequate flexibility and efficiency.

(*f*) Progress has also been relatively slow in the field of weather modification. This problem still depends primarily upon basic research to yield better understanding of the natural processes involved. Good progress is being made in the collection of data, by enlarged and

improved global networks with international collaboration, and by the brilliant records of the Tiros satellites. The work has been further handicapped by a critical shortage of scientists trained for research in meteorology. The NSF has aided this situation materially by grants for research and research facilities to qualified colleges and universities which provide a steady increase in output of trained scientists. Another difficulty is the enlistment of others than traditional meteorologists in this research, notably, physicists, chemists, mathematicians, and computer specialists—always a slow process in basic research.

(*g*) A continuing aim in the NSF is the staff recruitment of able scientists, mathematicians, and engineers who have the special qualifications for the type of basic research administration required. This type of science activity is relatively new in Government outside the fields of agriculture and public health, which, however, have comprised mostly applied research. These qualifications are ideally quite stringent—experience and accomplishment in some field of basic research, so as to be known and respected by the scientific community; breadth of scientific viewpoint and appreciation of the attitudes of academic scientists, understanding of university administration (and to some extent that of industrial research laboratories); familiarity with research equipment, its design, construction and use; ability in reviewing research material, conferring with research scientists, clarity of expression in reports and conferences; administrative sense and organizing ability; finally, good personal qualities and skillful participation in the work of the organization. An agency such as the NSF hesitates to try to recruit scientists from among those in the forefront of research in their fields; their current research contributions are undoubtedly more important. The best that can be done is to keep trying for the best qualified individuals and ultimately to retain a fully competent staff. Salary differentials do not now offer the obstacles they once did. The Foundation has had considerable success in securing capable scientists on a 1- or preferably 2-year leave of absence. In this way individuals with outstanding qualifications may be found and hopefully retained. Also the authorization (originally proposed by the NSF) to allow leave of absence from Federal employment, with pay, is an asset in keeping permanent staff members up to date in their fields.

21. When the Foundation first started, it limited itself to granting project grants and fellowships. Now we see it using many more forms of support and, in particular, managing large scientific ventures. Do you think it appropriate for the Foundation to operate research centers? If so, what balance should there be between freedom of research decisions for the scientists and responsibility for effective management and administration by the Foundation?

21. I do not think it appropriate for the Foundation to operate research centers directly, for example as done by NACA (Langley, Ames), and as now continued by NASA. In the case of basic research this leads to unnecessary and undesirable supervision and control. It also entails a stronger and more permanent Federal investment in research facilities with subsequent tendency toward loss of objectivity in NSF planning. It is well adapted to R. & D. laboratories with important Federal missions which do not compete with private enterprise. The most effective arrangement for the operation of research

centers supported by the NSF is the one in current use; namely, by private management under contract with some recognized institution, association, or corporation. The latter is advantageously done by bodies formed for the purpose by the interested scientists or their institutions, as done with Kitt Peak National Observatory or the National Center for Atmospheric Research. In such cases funds and Federal policy guidance are provided by NSF while responsibility and direct supervision come under the governing board which appoints the Director who is responsible for planning and operation. This permits increased flexibility in administration and research while at the same time it provides overall supervision of the contract and funds by the NSF.

22. Considering the signs that research and development funding for many Federal departments and agencies appears to be leveling off to what extent would you think it desirable for the Foundation to sponsor basic research of interest to them? If the NSF were to consider such a role, what effect would it have on the concept of the Foundation as a balance wheel for Federal support of basic research?

22. In view of the apparent leveling off of R. & D. funds among other Federal departments and agencies, it is of course desirable for the Foundation to confer regularly with them concerning their basic research needs and to cooperate in carrying on basic research important to their missions. However, it is my strong conviction that the present policy stated in Executive Order 10521 (1954) should be maintained; namely, that any agency concerned with R. & D. should conduct and/or support basic research in fields closely related to its mission. The key phrase is "closely related"; this requires interpretation. It is evident that up to a point, when R. & D. funds are reduced, the agency may use this definition in a narrow sense and confine its basic research support to highly essential areas. In such cases the Foundation may be able to help by taking on some of the broader areas of basic research which have relevance to the agency's business but which are obviously less essential. This would require an increase in the basic research appropriation for the NSF. But in my opinion it would be a severe drawback, indeed a catastrophe, for an agency to drop basic research entirely since, to be of maximum service, its basic research should be gained at firsthand and not secondhand. Besides, the NSF could never deal adequately with research requirements in special fields vital to an agency mission, such as underwater sound for the Navy, basic chemistry on explosives for Army ordnance or aerodynamics for the Air Force.

23. The subcommittee has heard testimony that research is inseparable from teaching at the graduate level. Does this imply that smaller colleges and universities which cannot mount vigorous research programs inevitably must withdraw from graduate instruction in the sciences? What should the Foundation do?

23. In considering the implications of the statement that research is inseparable from teaching at the graduate level, the major problems is not that of the smaller colleges and universities but rather that of the large institutions. Here the danger is that members of the graduate faculty may tend to take on more and more research at the expense of their teaching classes. The cumulative effect of this is to reduce the undergraduate or even graduate teaching time of the

research faculty. This may even be carried so far that certain graduate faculty members are never seen personally by the students in their classes and the students have no opportunity to hear them discuss their research. Of course, it is almost universal for such faculty members to have graduate students working on thesis problems. This in itself may be regarded as a fine combination of research and teaching although in some cases an active research faculty member may supervise the theses of so many graduate students he has little contact with them.

The problem of smaller colleges and universities is different. Some do not propose to develop graduate schools but prefer to prepare students to go elsewhere for graduate work. This is a legitimate and important role. Such institutions frequently have individual faculty members who are active in research and receive individual grants, especially from the NSF. Many college presidents of such institutions consider this an excellent arrangement. It has the advantage of bringing research into close touch with undergraduate instruction; indeed, it often provides opportunities for undergraduate students to serve as research assistants to faculty members.

The most serious problem arising in this connection is the increasing difficulty on the part of colleges and universities which are relatively less experienced or equipped for research in retaining good research scientists on their faculties. This has always been true to some extent, but within the last decade or so it has become more acute for a number of reasons—the increasing prestige of research, the widening salary differential, the growing use of "team" research and, as always, the importance of association with a number and variety of active researchers.

The Foundation should continue to take steps along the following lines:

(*a*) Increase the number and spread of individual research grants to faculty members of small colleges and universities (in general this requires additional funds so that it may not take place at the expense of important research in highly competent hands at the larger and more active research centers).

(*b*) By suitable selection and distribution of institutional grants, as funds permit, assist smaller institutions in recruiting faculty and facilities having latent capability and promise.

(*c*) Encourage and help to negotiate cooperative arrangements between small academic institutions and large institutions with highly developed graduate schools or in the neighborhood.

Similarly, encourage cooperation among neighboring institutions of similar stature, for the benefit of the group, as, for example, the cooperative arrangements in the North Carolina "Research Triangle" (Duke, North Carolina State, and the University of North Carolina), and among Amherst, Smith, Mount Holyoke, and the University of Massachusetts.

Response by Dr. Dael Wolfle, Executive Director, American Association for the Advancement of Science, to Questions of the Subcommittee on Science, Research, and Development

1. Recommendation No. 4 of your statement to the committee declared that the time has come for the creation of "a new kind of permanent agency or partner in the field of scientific manpower studies"; and you added that the National Science Foundation "is under too much pressure" of other work to do this job properly.

(a) Where do you think the initiative should come from in the move to establish the agency you suggest which would interpret, synthesize, criticize, and improve methodology of scientific manpower studies?

(b) Considering that the present NSF charter seems broad enough to include the activities you suggest for the new permanent agency, what are the advantages of this approach in comparison with strengthening the capability of the Foundation to move deeper into methodological and analytical work?

(c) Doesn't NSF really need to perform this function in order to do its overall job effectively?

1. (*a*) The initiative to establish an agency that would interpret, sythesize, criticize, and improve methodology of scientific manpower studies might come from the Bureau of the Budget, the Office of Science and Technology, or the National Science Foundation. I would suggest the NSF, because it has operating responsibilities and funds that could support the proposal.

(*b*) In response to a question following my testimony on July 1, I said that I did not think it necessary to change the wording of the organic act of NSF. Upon further consideration, it now seems to me that an extension of the wording might be desirable, for, as you suggested, it would provide specific authorization that might aid the Foundation in securing the necessary appropriations.

Nothing in the NSF charter would preclude undertaking or supporting such studies. That they have not done so to a sufficient extent has, I presume, resulted from three countervailing pressures:

(1) Priority has been given to the regular publication of basic statistical series such as "Federal Funds for Research, Development, and Other Scientific Activities" and analyses of the National Register of Scientific and Technical Personnel, and to the tabulation of data requested by congressional committees, the Office of Science and Technology, and other Government agencies.

(2) Personnel ceilings.

(3) Insufficient congressional interest in, or support for, an expansion of this area of Foundation responsibility. (An example was given by Dr. Bowen Dees in his testimony on August 4, when he cited an Appropriation Subcommittee reduction in

the requested budget for scientific manpower and policies studies, and a request that there be a further reduction in the following year.)

"Strengthening the capability of the Foundation to move deeper into methodological and analytical work" will require either additional funds or a curtailment of other Foundation activities.

(*c*) I do not think it essential that these studies be conducted by the NSF staff, although that is one possibility to consider. Whether the reports and analyses are prepared by NSF personnel or by members of an agency outside of NSF, they will be studied by, and will be useful to, staff members of NSF, the Office of Education, the Bureau of Labor Statistics, other Government agencies, and nongovernmental institutions. Some of the studies that should be conducted may be critical of present methods or show deficiencies in present statistical series. Assuming that the people involved are of equal competence, an NSF unit would be as well qualified as an outside body to make objective criticism of Government data-gathering and reporting methods and practices. I suspect, however, that critical reports are more likely to be published promptly, and that they would be more widely useful, if they came from outside one of the agencies being criticized.

It is a matter of judgment whether the methodological and analytical work should be done in NSF or outside. Arguments can be presented to support either decision. I think an outside agency would work more effectively.

2. In this connection, you testified that "no one has really given high priority to the job of collecting, maintaining, and reporting statistical information concerning the Nation's scientific and technical manpower." Do you believe the recent move by NASA (press release of August 5, 1965) to operate, by contract, its new Scientific and Technical Information Facility—which it calls "the world's largest collection of aerospace literature"—will help close this gap?

2. As I understand the NASA press release of August 5, the contract with Documentation, Inc., to operate its Scientific and Technical Information Facility calls for the collection, organization, indexing, and selective distribution of scientific and technical information that will be of value in connection with the exploration of space. This will be useful to NASA but will provide little, if any, information about scientific and technical manpower trends or problems.

3. Would you care to elaborate on your general testimony regarding the desirability of rewording the Organic Act of NSF?

3. See 1(*b*) above.

4. Do you think it might be advisable at least to permit NSF a broader scope in regard to operational projects or applied research in important areas?

4. I would not wish to prohibit NSF from engaging in operational projects or applied research. When the agency was established, more work of that nature was expected than has actually been carried out. Initially, the Foundation was authorized to engage in military research, and one of its first responsibilities was to conclude the Government's rubber research program.

In some areas there is need for a greater amount of applied research, and there is need also, in a number of sectors of the civilian economy, for work on the factors that help determine the usefulness of applied

research and the acceptance of its results. I have in mind some of the codes, regulatory arrangements, and inertia that tend to maintain the status quo instead of inviting innovation.

But some division of labor is necessary among the Federal agencies. The National Science Foundation has been the single Federal agency able to support scientific activities on a substantial scale that does not also have operational responsibilities. Our present policy permits the mission-oriented agencies to support pure or applied research in fields relevant to their missions, and encourages the National Science Foundation to support basic research selected on the criteria of scientific merit and promise, without regard to relevance to any particular missions. This policy seems to me to represent a sound balance. Consequently, although I would not wish to prohibit NSF from engaging to a larger extent in operational projects or applied research, I would recommend that its primary focus and the great bulk of its interest and support not be moved in the applied direction.

5. What about the "teeth or police power" you said is necessary for the effective gathering of manpower data from the various Government agencies? You said that NSF, even though designated as a "focal agency" for this function, can only coordinate agency activities by persuasion and voluntary agreement. Since the data collection function of NSF is so vital as a basis for science policy decisions and for long-range planning, what action do you think is necessary to give the Foundation the increased authority it needs?

5. I did point out that the "focal agency" function of NSF did not involve any "teeth or police power," and in the short run that fact may make it difficult for NSF to secure data or cooperation that it would like to have. However, I would not change the situation. The difficulties and problems that would be created by the assignment of coercive authority would, I fear, be greater than the difficulties of the present system.

6. In your editorial in Science on June 25, 1965, you speculate about possible changes in scope of NSF activities about the application of science. In your opinion, what are the principal arguments for and against such an extension of the Foundation's current responsibilities?

6. See 4 above.

7. You testified that faster reporting of manpower data would be possible with better equipment. Would you elaborate on this statement and perhaps indicate how much more money might be necessary to provide NSF with better equipment? What kind of equipment?

7. I do not know how to answer this question with enough precision to be useful. The equipment needs will depend upon the size and nature of the program, and that is under debate. After those decisions have been made, someone who is more of an expert than I on the capabilities of specific kinds of equipment would be better able to provide this information.

8. You also mentioned the desire for more information as one reason the Foundation is not providing satisfactory statistical services. Is the growth in demand more in information that it would be nice to have but is not essential, or is it in demand for information that is essential to policy and planning decisions concerning research and development?

8. Some of the additional information desired is of the kind that "would be nice to have but is not essential," and some would be of substantial use in policy and planning decisions. The distinction between these two categories depends in part upon the timeliness with which the information is collected and reported. Current information, promptly reported, can be useful in making policy and planning decisions. The same information, reported 2 years later, is of historical value, but no decisions can be based upon it. The type of data that I described as "flow information" would be useful in decisionmaking.

The ways in which manpower information might be analyzed and studied by different agencies and by interested persons outside of Government are varied indeed. NSF and the other responsible agencies will always have to establish priorities and collect only the kinds of data that seem to be of sufficiently general use to justify the costs involved. However, as the agencies gain in knowledge of how to use such information effectively, it is probable that the amount and variety that would be truly useful will increase.

9. The report of the National Manpower Council last July, entitled "Government and Manpower," observed a drastic shift away from preoccupation with numbers of scientific and technical people, to the quality of the required skills of the relatively small numbers of scientists and engineers of exceptional quality who are capable of working in new fields. What responsibility should the Foundation have for developing the methods to collect such information, and to collect and analyze it?

9. There has been a healthy increase in interest in obtaining information about the more highly qualified segment of the scientific and engineering population. No additional authority or responsibility for collecting such information is required. Insofar as educational attainments and records of positions held serve to indicate high quality, the data for scientists are on record in the National Register. The Office of Scientific Personnel of the National Acaedmy of Sciences, with financial support from the National Science Foundation and the National Institutes of Health, has a complete file of all persons who attained the doctorate from American University since 1920. As a part of the operation of the doctoral records file, data are collated from NSF and other graduate fellowship programs and other sources. The amount of information recorded varies substantially from individual to individual, but the basis is already established for a fairly comprehensive file of information about the more highly qualified segment of the population.

10. Advances in science and technology may cause imbalances between demand and supply for scientists and engineers.

(a) To what extent should the Foundation's acquisition and processing of data about money and manpower for research and development be adapted to generate early warning signals of such change? If so, how might this be done?

(b) What is known about the size and makeup of that part of the population which has the basic capability to become scientists or engineers?

(c) Could more graduate students be supported without compromising quality? There was some testimony at the hearings that the the ceiling may already have been reached. Do you think so?

10. (*a*) It will be necessary to do some exploring to learn how the processing of data about money and manpower could generate reliable, early warning signals of prospective imbalances between demand and supply. This certainly should be one of the functions, but the art is not yet well developed.

(*b*) On the basis of school grades, intelligence tests, or similar measures of ability, scientists and engineers are a somewhat heterogeneous group. Practically all come from the top half of the distribution, and in round numbers, approximately three out of four come from the top 15 or 20 percent of the distribution. Whether persons of this level of ability become scientists or engineers or choose to go into other fields of work depends upon interests, educational opportunities, and market conditions. There never seems to be enough men of really top ability in any field, but there is an adequately sized group of young people coming through the elementary and secondary school system to furnish foreseeable needs for scientists or engineers. Cultural, educational, and financial handicaps are more severe constraints than lack of ability.

(*c*) There are very able high school graduates who do not enter college, although their number is much smaller now than it was a decade or two ago. There are high-quality graduate students who do not enter graduate work. We are moving toward a ceiling but we are not there yet. How much more leeway we have varies from field to field. The percentage of recipients of bachelor's degrees in physics who go on to take the doctorate is much higher than the percentage in engineering. There could, therefore, be a greater increase in the number of graduate students in engineering than in physics before we encountered the problem of lowering quality. Another factor that must be considered, however, is the ability of the graduate schools to provide good educational opportunities to larger numbers of students.

11. What studies is the association (or anyone else you know of) now sponsoring to provide more information about the nature and rate of obsolescence for scientific and engineering personnel? Have any effective countermeasures been devised?

11. The AAAS is not sponsoring any studies of the nature and rate of obsolescence for scientific and engineering personnel. I have heard of some such studies, but am not acquainted with them.

One very effective countermeasure has long been in use: direct personal involvement with new knowledge. The man who is actively engaged in research continues to learn. He will not get out of date nearly so rapidly as he otherwise would.

Reading, study, special courses, and a basic education that emphasizes principles rather than current practice are all recognized as useful means of retarding obsolescence. We need more opportunities for persons in midcareer to take time out for systematic refresher courses and to bring themselves up to date. These opportunities are particularly needed by scientists and engineers who are primarily engaged in teaching, design, manufacturing, and in general activities other than research and development.

12. There has been testimony that the best graduate students are frequently unavailable for teaching because the terms of their research fellowship specifically prohibit this activity. Do you believe more research grants should have room for some teaching? Would such flexi-

bility benefit the graduate as well as help in the training of undergraduates?

12. Many Federal fellowships did specifically prohibit the holder from doing any teaching. That prohibition has to a considerable extent been relaxed. Research grant funds can ordinarily not be used to support classroom teaching, although teaching of another and very important kind does go on between the senior and junior members of a research team.

At present, the money to support graduate students comes from several sources and is categorized by function. Money for teaching assistantships comes primarily from university sources; money for research assistantships comes largely from Federal sources, and so does money for fellowships. During their graduate years, it is likely to be useful to almost all graduate students to have two, and in many cases all three, of these kinds of experience. One or two years might be spent as a research assistant, a year or two as a teaching assistant, and the final year on a fellowship, without duties other than to complete his dissertation. Arrangements of this kind could become more general if the university could assign graduate students to teaching assistantships, research assistantships, or fellowships in accordance with their individual stages of development and in terms of what appeared to be most useful for the following year. The universities could have this flexibility, probably with no increased cost to the Government, if the Federal funds that are now granted for fellowships and traineeships, and for research assistantships on project grants, were pooled and given to the universities for the support of graduate students, with the understanding that many of the students would render service in return for their support.

There are administrative difficulties with this proposal, but stating it as a goal indicates the desirability of introducing greater flexibility into the ways in which the graduate departments can use fellowship, traineeship, and research assistantship funds. I believe that the change would benefit graduate students. Whether it would have a noticeable effect on undergraduate instruction is hard to say, but the effect, if there is one, would be more likely to be beneficial than harmful.

RESPONSE BY DR. CHALMERS W. SHERWIN, DEPUTY DIRECTOR, DEFENSE RESEARCH AND ENGINEERING (RESEARCH AND TECHNOLOGY), DEPARTMENT OF DEFENSE, TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

---

1. Following up your testimony of July 1, what is your view concerning the distinction between mission-oriented basic research, as supported by Department of Defense, and free or undirected basic research, as supported by NSF? What do you believe, as a matter of national policy, the distribution of Federal funds between the two ought to be?

1. Basic research supported by the Department of Defense is in all cases directly or indirectly related to defense needs. No such requirement characterizes NSF-supported basic research. Both types of research are aimed at improved understanding of the workings of nature, and both require selection of highest-quality research investigators, but DOD-supported research has passed through an extra "filter" that imposes the criterion of defense relatedness.

The question of optimum distribution of research effort between DOD and NSF is a difficult one. Rather than reply to it directly, I should prefer to make the comparison with organizations basically more similar to DOD, such as AEC and NASA. These resemble DOD in carrying heavy technological development responsibilities. In my opinion mission-oriented agencies of this kind are the country's largest "consumers" of general research. They have to be, for their future depends on it. The DOD is the largest such agency and should in my opinion be supporting a scientific research program in somewhat the same relative proportion to its total R.D.T. & E. program as the other comparable agencies. This is not at all the case. DOD supports relatively the smallest research program of the three agencies I mentioned, and in basic research supports the smallest program not only in relative but in absolute terms as well.

I believe that research, including basic research, should be supported by the major mission-oriented agencies approximately proportionally to the development load each carries, because of the tendency of today's research to control the effectiveness of tomorrow's development. On this basis either DOD should have a larger research program, or the other mission-oriented agencies should have smaller ones. I believe the former, because all information I have been able to gather to date indicates the multiplication factor of payoff from past DOD research investments to be impressively high, and even the marginal payoff from further investment to be in all probability sufficient to justify it in cost/effectiveness terms. I mentioned in my testimony that we now have in process a study aimed at providing a more quantitative basis for conclusions in this area.

2. How much basic research is DOD currently supporting and what are the DOD plans with respect to the future support of such research and its magnitude in relation to other budget items? Where do you

believe the basic research of principal interest to the DOD should be performed?

2. Following are the basic research levels supported by DOD for the years indicated:

	Obligations
Fiscal year 1964	$259,600,000
Fiscal year 1965	293,000,000
Fiscal year 1966	323,600,000

You will note that the above numbers represent at least a 10-percent increase each year. The current 5-year programing plan for DOD research calls for approximately a 10-percent increase per year. The above numbers may be compared with the current Department of Defense R.D.T. & E. level of approximately $6.5 billion annually.

The basic research of interest to the DOD should be performed partly in-house in our own laboratories. The reasons for this include the need to maintain in-house laboratory quality by attracting talented scientists early in their careers, stimulation of ideas within the laboratory, provision of working-level contacts with the latest developments on the international research front, etc. The numbers of scientists required for these purposes are not large; they represent a very small fraction of the total U.S. scientific community. The remainder of our basic research must necessarily be performed where the bulk of the scientific talent has traditionally resided and still resides—in the Nation's colleges and universities, particularly those having first-quality graduate schools—and in industrial or not-for-profit laboratories. About geographical distribution I shall comment in connection with question 4, below.

3. The point has been made during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency X, agency Y, or both. More specifically:

(a) What guidelines or criteria has the Department of Defense established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of DOD's jurisdiction and, therefore, should, or should not, be supported by the Department?

(b) If written criteria have been established by DOD, please submit a copy thereof of the committee.

3. Attached is a copy of DOD Directive 3210.1 and principal references contained therein. This directive provides the only written criteria currently in existence. It will be noted that the criteria are nonspecific, in that they call only for relevance to the "needs" and the "mission" of the Department of Defense. The mission and needs of the Department are in fact so diverse that it would be very difficult to formulate more definitive constraints that would not interfere with proper delegation of authority to the services. I believe that for effective management such delegation is in general necessary in order to bring together authority, responsibility, and specific technical and programmatic knowledge at the critical decisionmaking level.

OCTOBER 26, 1964.

DEPARTMENT OF DEFENSE DIRECTIVE NO. 3210.1

Subject: Administration and support of basic research by the DOD.
References:
(a) Executive Order 10521, as amended, "Administration of Scientific Research by Agencies of the Federal Government."
(b) DOD Directive 3210.2, "Policy on Basic Research Grants and Title to Equipment Purchased Under Grants."
(c) Section XV, Armed Services Procurement Regulation.
(d) DOD Directive 3210.1, "Policy on Basic Research," November 12, 1957 hereby canceled).

I. PURPOSE

This directive states the policy of the Department of Defense on the administration and support of basic research.

II. CANCELLATION

Reference (d) is hereby superseded and canceled.

III. DEFINITION OF BASIC RESEARCH

Basic research is that type of research which is directed toward increase of knowledge in science. It is research where the primary aim of the investigator is a fuller understanding of the subject under study.

IV. BACKGROUND

A. Reference (a) provides broad guidelines for administration of basic scientific research by Federal agencies. These guidelines state that while the National Science Foundation shall be increasingly responsible for providing Federal support for general purpose basic research, the conduct and support by other Federal agencies of basic research in areas which are closely related to their missions is recognized as important and desirable and shall continue.

B. The Director of Defense Research and Engineering is responsible to the Secretary of Defense for the review and direction of the basic research program of the military departments and other agencies of the Department of Defense authorized to conduct or support basic research, and shall insure that this program is executed according to the provisions of reference (a). This review will be of maximum effectiveness if all elements of the Department adhere to the same fundamental principles in their conduct and support of basic research

V. PRINCIPLES

A. Basic research is essential to the development of military power.

B. Continuity is essential to successful basic research. Therefore, long-term planning and funding of basic research will be employed to the maximum possible extent.

C. Basic research may be conducted by competent scientists in universities and nonprofit institutions, industry, military laboratories, or elsewhere.

D. Sustained support of basic research will result in increased effectiveness and economies in military programs.

E. Free and effective communication among scientists is important to basic research.

VI. POLICY

A. It is the policy of the Department of Defense—

1. To conduct and support a broad and continuing basic research program to provide fundamental knowledge, with emphasis on that related to the needs of the Department of Defense; and

2. To assure full utilization of our scientific resources and to extend those resources in those areas of science relevant to the mission of the Department of Defense; and

3. To maintain, through such a program, effective communication among the scientists of the Department of Defense and the scientists of the universities and industry; and

4. To coordinate this program of basic research with the National Science Foundation; and

5. To encourage the support of basic research by other Government and private agencies.

VII. IMPLEMENTATION

A. It is the responsibility of the Director of Defense Research and Engineering to produce, on a continuing basis, a sound basic research program through the coordination and integration of the elements of the program among the military departments and other agencies of the Department of Defense authorized to conduct or support basic research.

B. The Department of Defense provides support of basic research by—

1. *Support of in-house laboratories.*—Basic research in laboratories of the Department of Defense or in laboratories of other Government agencies, best qualified for such work in particular areas, should be encouraged.

2. *Grants to and contracts with educational and nonprofit institutions.*—In situations appropriate for grants under the provisions of reference (b), the grant instrument is the preferred method of supporting basic research by educational and other nonprofit institutions.

3. *Contract with industry.*—Contracts specifically for basic research may be made with industrial contractors (including small businesses) which have a recognized special competence in a given area. In the administration of the provisions of reference (c) which relate to the allowability of a contractor's independent research costs under certain Department of Defense contracts, favorable consideration should be given to independent basic research.

C. The military departments and other agencies of the Department of Defense authorized to conduct or support basic research will provide the Director of Defense Research and Engineering with such information as he may require in order to carry out his responsibilities under this directive, including annual reports through established administrative and fiscal channels of the following, by contract or grant and dollar value:

1. Basic research performed in Government laboratories.
2. Basic research grants to educational and nonprofit institutions.
3. Basic research contracts to educational and nonprofit institutions.
4. Basic research contracts to industrial contractors, including small business.
5. Independent basic research recognized as an allowable cost in an advance agreement under the provisions of reference (c). Such costs shall be reported via the Assistant Secretary of Defense (Installations and Logistics).

D. Within 90 days of the effective date of this directive, two copies of implementing instructions issued by the military departments will be forwarded to the Director of Defense Research and Engineering.

VIII. EFFECTIVE DATE

This directive is effective immediately.

ROBERT S. MCNAMARA,
Secretary of Defense.

[Reprinted from the Federal Register of Friday, Mar. 19, 1954]

MARCH 17, 1954—EXECUTIVE ORDER CONCERNING GOVERNMENT SCIENTIFIC RESEARCH, THE NATIONAL SCIENCE FOUNDATION, AND THE INTERDEPARTMENTAL COMMITTEE FOR SCIENTIFIC RESEARCH AND DEVELOPMENT

TITLE 3—THE PRESIDENT

EXECUTIVE ORDER 10521

ADMINISTRATION OF SCIENTIFIC RESEARCH BY AGENCIES OF THE FEDERAL GOVERNMENT

WHEREAS the security and welfare of the United States depend increasingly upon the advancement of knowledge in the sciences; and

WHEREAS useful applications of science to defense, humanitarian, and other purposes in the Nation require a strong foundation in basic scientific knowledge and trained scientific manpower; and

WHEREAS the administration of Federal scientific research programs affecting institutions of learning must be consistent with the preservation of the strength, vitality, and independence of higher education in the United States; and

WHEREAS, in order to conserve fiscal and manpower resources, it is necessary that Federal scientific research programs be administered with all practicable efficiency and economy; and

WHEREAS the National Science Foundation has been established by law for the purpose, among others, of developing and encouraging the pursuit of an appropriate and effective national policy for the promotion of basic research and education in the sciences:

NOW, THEREFORE, by virtue of the authority vested in me as President of the United States, it is hereby ordered as follows:

SECTION 1. The National Science Foundation (hereinafter referred to as the Foundation) shall from time to time recommend to the President policies for the Federal Government which will strengthen the national scientific effort and furnish guidance toward defining the responsibilities of the Federal Government in the conduct and support of scientific research.

SEC. 2. The Foundation shall continue to make comprehensive studies and recommendations regarding the Nation's scientific research effort and its resources for scientific activities, including facilities and scientific personnel, and its foreseeable scientific needs, with particular attention to the extent of the Federal Government's activities and the resulting effects upon trained scientific personnel. In making such studies, the Foundation shall make full use of existing sources of information and research facilities within the Federal Government.

SEC. 3. The Foundation, in concert with each Federal agency concerned, shall review the scientific research programs and activities of the Federal Government in order, among other purposes, to formulate methods for strengthening the administration of such programs and activities by the responsible agencies, and to study areas of basic research where gaps or undesirable overlapping of support may exist, and shall recommend to the heads of agencies concerning the support given to basic research.

SEC. 4. As now or hereafter authorized or permitted by law, the Foundation shall be increasingly responsible for providing support by the Federal Government for general-purpose basic research through contracts and grants. The conduct and support by other Federal agencies of basic research in areas which are closely related to their missions is recognized as important and desirable, especially in response to current national needs, and shall continue.

SEC. 5. The Foundation, in consultation with educational institutions, the heads of Federal agencies, and the Commissioner of education of the Department of Health, Education, and Welfare, shall study the effects upon educational institutions of Federal policies and administration of contracts and grants for scientific research and development, and shall recommend policies and procedures which will promote the attainment of general national research objectives and realization of the research needs of Federal agencies while safeguarding the strength and independence of the Nation's institutions of learning

SEC. 6. The head of each Federal agency engaged in scientific research shall make certain that effective executive, organizational, and fiscal practices exist to ensure (a) that the Foundation is consulted on policies concerning the support of basic research (b) that approved scientific research programs conducted by the agency are reviewed continuously in order to preserve priorities in research efforts and to adjust programs to meet changing conditions without imposing unnecessary added burdens on budgetary and other resources, (c) that applied research and development shall be undertaken with sufficient consideration of the underlying basic research and such other factors as relative urgency, project costs, and availability of manpower and facilities, and (d) that, subject to considerations of security and applicable law, adequate dissemination shall be made within the Federal Government of reports on the nature and progress of research projects as an aid to the efficiency and economy of the overall Federal scientific research program.

SEC. 7. Federal agencies supporting or engaging in scientific research shall, with the assistance of the Foundation, cooperate in an effort to improve the methods of classification and reporting of scientific research projects and activities, subject to the requirements of security of information.

SEC. 8. To facilitate the efficient use of scientific research equipment and facilities held by Federal agencies:

(a) the head of each such agency engaged in scientific research shall, to the extent practicable, encourage and facilitate the sharing with other Federal agencies of major equipment and facilities;

(b) A Federal agency shall procure new major equipment or facilities for scientific research purposes only after taking suitable steps to ascertain that the need cannot be met adequately from existing inventories or facilities of its own or of other agencies; and

(c) The Interdepartmental Committee on Scientific Research and Development shall take necessary steps to ensure that each Federal agency engaged directly in scientific research is kept informed of selected major equipment and facilities which could serve the needs of more than one agency. Each Federal agency possessing such equipment and facilities shall maintain appropriate records to assist other agencies in arranging for their joint use or exchange.

SEC. 9. The heads of the respective Federal agencies shall make such reports concerning activities within the purview of this order as may be required by the President.

DWIGHT D. EISENHOWER.

THE WHITE HOUSE,
March 17, 1954.

[No. 3210.2, ch. 2 (reprint) June 30, 1964; supersedes ch. 1, Mar. 29, 1963]

DEPARTMENT OF DEFENSE DIRECTIVES SYSTEM TRANSMITTAL

REPRINT OF DOD DIRECTIVE 3210.2, "POLICY ON RESEARCH GRANTS AND TITLE TO EQUIPMENT PURCHASED UNDER GRANTS," NOVEMBER 19, 1962

The attached reprint of DOD directive 3210.2, "Policy on Research Grants and Title to Equipment Purchased under Grants," November 19, 1962, contains the following changes, which are indicated by asterisks:

1. Page 1, in the references: Deletion of former reference (*c*), "DOD Instruction 3210.3, August 29, 1959 (canceled by DOD Transmittal 64–20, June 30, 1964); new reference (*c*) substituted—"DOD Instruction 5100.38, dated March 19, 1963."
2. Page 4, section VII: Deletion of the sentence in parenthesis referring to the canceled reference (*c*)—3210.3
3. Page 5, section VIII: Deletion of subparagraph "D" referring to canceled 3210.3 section XI: Substitution of new paragraph referring to existing military department implementations and amendments thereto.

Implementation.—This amendment is effective immediately. Two copies of implementing instructions shall be forwarded to the Director, Defense Research and development within 60 days.

MAURICE W. ROCHE,
Administrative Secretary.

[Reprint with changes through June 30, 1964]

NOVEMBER 19, 1962.[1]

DEPARTMENT OF DEFENSE DIRECTIVE NO. 3210.3

Subject: Policy on research grants and title to equipment purchased under grants.

References:

(*a*) Public Law 85–934, "An act to authorize the expenditure of funds through grants for support of scientific research and for other purposes," approved September 6, 1958.

(*b*) Public Law 87–577, "Department of Defense Appropriation Act, 1963," section 540.

*(*c*) DOD Instruction 5100.38, "Defense Documenation Center for Scientific and Technical Information (DDC)," March 19, 1963.

(*d*) DOD Instruction 4105.54, "Miscellaneous Procurement Reports," June 20, 1961.

(*e*) DOD Directive 3210.2, subject as above, August 25, 1959 (hereby canceled.)

---

[1] First amendment (ch. 2, June 30, 1964).

I. AUTHORITY AND PURPOSE

Pursuant to reference (*a*), this directive—

A. Establishes uniform DOD policy for (1) making grants to institutions of higher education and to nonprofit organizations for the support of scientific research and (2) vesting in such institutions or organizations the title to equipment purchased with grant funds;

B. Delegates authority for carrying out the responsibilities of the Secretary of Defense under reference (*a*).

II. CANCELLATION

Reference (*c*) is hereby superseded and canceled.

III. SCOPE AND APPLICABILITY

This directive applies to Department of Defense components and the military departments which program funds in Program Elements of the Research Aggregation of Program VI, Research and Development, or any other project which meets the defining criteria of the former as stated in section IV.C below. It covers the expenditure of such funds for grants in support of the purposes set forth in section I. The policy for vesting of title to equipment purchased with contract funds is excluded from the scope of the directive and will be subject to the Armed Services Procurement Regulations.

IV. DEFINITIONS

As used herein—

A. "Grant" means an award of funds included in a written agreement executed by a grantor agency of the Department of Defense through its contracting activities under the authority of reference (*a*).

B. "Grantor agency" means a military department or other agency within the Department of Defense that is authorized pursuant to section IX below, to make grants in support of research.

C. "Research" includes all effort directed toward increased knowledge of natural phenomena and environment, efforts directed toward the solution of problems in the physical, biological, and behavioral sciences that have no clear direct military application and address themselves primarily to the expansion of knowledge in these various areas of science.

D. "Educational institution or other nonprofit organization" means any corporation, foundation, trust, or institution operated for educational or primarily scientific purposes, not organized for profit, no part of whose net earnings inures to the profit of any private shareholder or individual.

V. BACKGROUND AND OBJECTIVES

A. The Department of Defense is responsible for assuring that the scientific research necessary to the discharge of its statutory responsibility is given adequate support.

B. Prior to the enactment of Public Law 85–934, the Department of Defense was limited to the use of research contracts in obtaining the services desired of educational or other nonprofit organizations toward this end.

C. The authority to make grants to such organizations for the purpose of conducting research and, as appropriate, to vest title to equipment purchased with grant funds in the institution or organization conducting the research, has increased the flexibility of the Department of Defense in arranging for the conduct of pertinent research.

D. Compliance must be insured with liimtations such as that contained in reference (*b*) which specifies that, "none of the funds provided herein shall be used to pay any recipient of a grant for the conduct of a research project an amount for indirect expenses in connection with such project in excess of 20 percentum of the direct costs," and similar later enactments.

VI. POLICY

A. It is the policy of the Department of Deefnse to employ this discretionary flexibility by selecting either a research contract or a grant for the support of research at an educational or other nonprofit institution on the basis of a de-

termination as to which best furthers the objectives of the Department of Defense.

1. Determination in favor of a grant in lieu of a contract shall be made only after full consideration is given to the nature of the proposed research, as well as the magnitude and extent of the support. In general, grants shall not be made for an initial period of more than 5 years. This determination may depend on but is not restricted to the following factors:

(*a*) *Support of an investigation of broad scope.*—A grant may be more suitable if the grantee is to carry out investigations not profitably confinable to a specific field or particular approach.

(*b*) *Simplicity and economy in execution and administration.*—A grant may be more siutable if there is either no need or no opportunity for detailed supervision by the supporting agency and for periodic progress reports by the investigator. The factor of economy, resulting from the simplification of accounting and auditing procedures, applicable to research contracts, should also be considered but not in competition with substantive factors.

(*c*) *Payment.*—Performance of a task may be advantageously affected by extending to the grantee the greater flexibility of payment which the grant arrangement offers in comparison with the contract.

(*d*) *Multiple sponsorship.*—The grant may be preferable in cases where the Department of Defense intends to support specific portions of the direct costs of a definite research program toward whose support other agencies, authorized to make grants, and nongovernmental groups are also contributing.

2. Title to all or any part of the equipment purchased with research grant funds may be vested in the organization or institution that has conducted or will conduct the research. This vesting of title may be effected in the grant agreement and may be inclusive or specific. Prior to the vesting of title, it must be determined that such actions furthers the objectives of the Department of Defense. This determination may be based on but is not restricted to factors such as these:

(*a*) The retention of title in the Department of Defense creates an administrative burden not warranted by the value of the equipment.

(*b*) The administration and keeping of records by the educational or other nonprofit organization becomes prohibitively complicated or expensive.

(*c*) The expense involved in redistributing or relocating particular equipment exceeds the value of the equipment.

B. Research, development, and evaluation type appropriations of the Department of Defense are available for making grants in accordance with the policy set forth in this directive.

C. The services of the Defense Documentation Center (reference (*c*)) will be available to Department of Defense grantee institutions in the same manner that these services are provided to Department of Defense contractors and according to the same procedures.

VII. GRANT AGREEMENTS

The grant agreement shall be brief in format, containing only those provisions which are required by specific statutes or for the protection of the fundamental interests of the Government. This includes matters such as the limitation of indirect costs to at most 20 percent of the total direct costs; the maintenance of records sufficient to enable a determination that grant funds were expended for the purposes of the grant; the acquisition for the Government, in accordance with the patent and data policies of the Department of Defense set forth in section IX of the Armed Services Procurement Regulation, appropriate rights in inventions and data arising out of the research; and provisions for the revocation of the grant.

VIII. ADMINISTRATION OF GRANTS

A. In fixing the total amount of a grant before it is awarded, the applicable cost principles of parts 2 and 3, as appropriate, of section XV of the armed services procurement regulations will be used as a guide. Appendix C of the regulation will also provide guidance in the handling of property supplies, acquired under a grant, to which the Government retains title.

B. In accordance with reference (b), the indirect cost rate, used for determining grant amounts, shall exceed in equivalence neither 20 percent of the

total direct costs nor the indirect cost rate that has been most recently determined under applicable procedures at the grantee institution for comparable research contracts of the Department of Defense.

C. Except in the case of revocation, grant amounts as determined at the time of award will not be adjusted.

IX. DELEGATION

The authority vested in the Secretary of Defense pursuant to sections 1 and 2 of reference (a) is hereby delegated to the Secretaries of the Army, the Navy, and the Air Force, and to the Director of Defense Research and Engineering for grants of $1 million or less. Grants in excess of this amount will require approval of the Secretary of Defense. This authority may be redelegated to research activities whose responsibilities include the support of research at educational or other nonprofit institutions for grants of $500,000 or less. Grants exceeding $500,000 but of $1 million or less will require approval of the Secretary of the Department concerned or of the Director of Defense Research and Engineering.

X. REPORTING

Reporting pursuant to section 3 of reference (a) will be accomplished in accordance with reference (d).

XI. IMPLEMENTATION

Implementation of this directive will generally be in accordance with the following departmental implementations: Army—AR 70–5, March 6, 1964; Navy—ONR 3900, 10B, March 8, 1963; Air Force—OAR regulation 70–1, April 12, 1963; two copies of all revisions to these implementations shall be forwarded to the D.D.R. & E. within 10 working days after publication.

XII. EFFECTIVE DATE

This directive is effective immediately.

ROSWELL GILPATRIC,
Deputy Secretary of Defense.

4. In response to a question at the hearing, you indicated that DOD frequently awards contracts at times when the technical, administrative, and management criteria between the top several contractors is very close and rather difficult to decide. In such a situation, you said, DOD still does not consider factors of geographical distribution. Please explain DOD's policy in this regard, and why it believes geographical considerations to be totally inappropriate?

4. There was no intention on my part to imply that geographical considerations are totally inappropriate. The question of governmental policy on the geographical distribution of the research funds of mission-oriented agencies in cases in which other considerations are indecisive is of widespread concern in Government. The Federal Council for Science and Technology has under current consideration a definite policy statement applicable to this issue that will provide guidance to all agencies.

5. What is your reaction or response to the Federal Council for Science and Technology interim report for 1963, which states that no usable data were obtained from Federal agencies in an effort to develop projections of agency requirements for funds through 1970?

5. It is my understanding that the FCST report for 1963 did obtain useful projections for research programs out through 1970 when taken on an individual agency basis. Difficulty was experienced, however, when an attempt was made to consolidate these data into an overall projection for the Federal Government. Differences in definitions, categorization, and bases for estimates made it impossible to consoli-

date the individual agencies' data into a common form. Even though most agencies had valid plans, these were formed for their own purposes, not compatible as to format, definitions, time period, etc., with other agency programs. Certain technical areas such as materials and oceanography had well-developed plans. In such instances it has proved possible to project on a functional, scientific area, or commodity basis. Since it is the Government's principal function, however, to meet broad social needs, and since the agencies charged with meeting these needs can do so only by using science and technology as tools. I believe that plans formulated on a mission-oriented basis should always have priority over plans formulated on a technology-oriented basis.

The FCST is well aware of this problem and is currently working toward a compilation of usable data.

6. To what extent does DOD depend upon scientific and engineering manpower information from NSF in program planning and in decisions to undertake new programs? What manpower information does DOD require that it is not now receiving from NSF?

6. Agencies of the DOD keep informed about broad manpower trends through information supplied by the NSF. However, the DOD does not possess any quantitative methodology to deal with scientific manpower utilization and planning problems. To be effective on a national scale such a methodology, if it existed, would have to be used consistently throughout the Federal Government. No adequate theoretical basis for national manpower planning exists, nor have we developed an adequate mechanism of manpower forecasting. Even if a proven theory existed, its implementation in a nonregimented society would present serious difficulties. It is not clear that the problem of optimum national manpower allocation has been solved even in regimented societies.

The DOD would like to receive more complete and up-to-date manpower data from NSF and to see that agency assume, with the firm backing of the Congress, a greater degree of leadership in developing the methodology for understanding and applying data in the manpower field.

7. Is it your view, as a responder to NSF requests for statistical information on research and development, that the guidelines furnished provide for consistency of data submitted by various agencies? How is the preparation of this data monitored to insure its accuracy and completeness?

7. From all past indications, it is believed that the NSF constantly strives to issue guidelines and instructions in such a manner as to insure that the statistical data reviewed by NSF for their various studies and surveys are on a comparable basis. This is, of course, not always possible in every detail but a genuine effort is made in this direction. It must be borne in mind that problems of categorization, particularly in such loosely structured areas of human endeavor as scientific research, are intrinsically very difficult.

The NSF has analysts who work with representatives of each agency before, during, and after each survey is conducted. There is a constant exchange of views and checking of data between the NSF and DOD representatives. Not only is this true at the level of the Office of the Secretary of Defense, but representatives of the Army, Navy,

Air Force, and the defense agencies very frequently participate in the discussions and meetings.

8. How useful is the Science Information Exchange to DOD and to what extent does DOD cooperate with the exchange?

(a) Would you comment on the reasons why only basic research information, up to the present, has been submitted by DOD to the Science Information Exchange?

(b) Do you believe that SIE can potentially supply the research and development project information needed by DOD management in its program planning?

8. There were 73 requests from DOD offices to SIE in fiscal year 1964. The figure for fiscal year 1965, as of March 1965, was 113 requests. Because of SIE's background as a medical and biological sciences information facility, the large majority of DOD users of SIE have been associated with the DOD medical and biological sciences research program.

DOD policy is to cooperate with the Science Information Exchange. There are now on file with SIE approximately 7,000 records representing the fiscal year 1965 basic research program. We expect to bring these records up to date this October, using the computer-based "work-unit" information system inaugurated within DOD last January.

The reason why only basic research information, up to the present, has been submitted by DOD to the Science Information Exchange involves the problem of military security classification. The basic reresearch program is almost entirely unclassified. It reflects and makes available to the general public a balanced picture of the total DOD interest in different areas of basic research. Data covering the details of applied research work are for the most part classified. Making available to SIE only the data on unclassified applied work would present a very misleading picture of the DOD R. & D. program. Even if the individual projects of our applied research program were all unclassified, we should question the advisability of treating as unclassified the entire program in summary form, because of the clear inferences that an analysis of the total applied research would provide regarding future weapon developments.

I do believe that SIE cannot supply all the research and development project information needed by DOD in its management and program planning. The amounts and kinds of information necessary for R. & D. program planning by local management, middle management, and upper management within DOD are very extensive, and include as a part the summary information normally filed by SIE. It would be impractical to file the complete data at a central government point such as SIE. I believe that the alternative method of having each agency keep its own information but with the summary part in a common digital language and format is more practical and more efficient. If the R. & D résumé system is widely implemented, a Government-wide search for any set of related work can easily and quickly be done and the security problem is quite manageable.

9. What studies are DOD or NSF sponsoring to provide more information about the nature and rate of obsolescence for scientific and engineering personnel, and about effective countermeasures? In any event, what has been done to attract older professional people back to school in order to update their technical capabilities? Are we possibly

ignoring or wasting this technical manpower resource? In other words, do we have any program for reeducating older scientists and engineers whose early college training may be obsolete? What suggestions do you have for providing reasonable access to continuing, lifelong education for scientists to prevent obsolescence? In this connection, would future shifts in large Federal technology programs—let us say, away from military R. & D. toward environmental pollution studies—obsolete certain groups of scientists and engineers?

9. No studies are currently being sponsored by the DOD to provide information specifically about obsolescence of scientific and engineering personnel. In this connection I might remark that one of the main interests in my office during the coming year is to determine means of utilizing our in-house laboratory technical and scientific capabilities most effectively and of upgrading our talent, both junior and senior. I have established a small study group to gather data necessary to proceed with this problem.

The Department of Defense emphasizes training and career development of its in-house employees, and encourages similar solicitude for employee career development among defense contractors. A great deal of job "retreading" has taken place in the national economy as a whole, under the stimulus of economic necessity. Government agencies such as NASA and DOD have had considerable experience in this connection during the last decade; e.g., in moving into the new environment of space, etc. It is true, however, that most of the specific devices in effect for furthering advanced education, such as in-house laboratory or company fellowships, are utilized mainly by young people for the completion of their education. Very little is being done to my knowledge specifically to attract older professional people back to school. Were the need for such action strongly felt at local management levels in both Government and industrial laboratories, where greatest familiarity with the problem exists, sufficient authority is considered to reside there to permit local solutions to be sought.

It is my opinion that future shifts in large Federal technology programs, including the one mentioned of environmental pollution studies, are more apt to provide revitalized technical challenges and continuing employment to broadly educated scientists and engineers than to render them obsolete. Very narrowly trained and early overspecialized scientists and engineers may have to pay a penalty for their limited education. But that penalty would probably have to be paid in one way or another in any circumstance, in view of the pace of modern technological change. There is a lesson to be learned here about the importance of starting each scientist and engineer off with a broad foundational education in basic science, prior to specialized training, in order to provide him in later life with the best job insurance he can have—personal adaptability to change.

10. With the advent of the space age the charge has been made that rapid development of space technology has drawn many of the best professors, practicing engineers, and students away from aeronautical engineering into the more intriguing and glamorous field of space engineering, research, and development. Is this true? And if so, is it cause for concern? Is any program in existence or contemplated to assure a balanced input of graduate space scientists and aeronautical engineers into the scientific and technological communities?

10. It is true that many professors and practicing engineers have tended to move away from consideration of the low-speed conventional aircraft toward the very high performance aircraft and missiles or space vehicles. If for no other reason, the more ready availability of jobs and funds in the latter field would cause the transition. This doesn't necessarily mean that the best people have moved nor does it mean that the knowledge requisite for advances in the lower speed vehicles must suffer unduly, although examples of such penalties already experienced can be found.

Many, if not most, of the technologies employed for the design and fabrication of space vehicles are also fundamental to current aircraft. The primary risk I envision is that engineers trained and skilled in the space field, with its premium on peak performance, will have some difficulty at a later date to think in terms of the more prosaic materials, components, and fabrication techniques that are useful and economically desirable for lower performance vehicles, but I believe that a good engineer can overcome this difficulty.

In terms of absolute numbers of people, I suspect that fewer are required for studies and design work of the low-speed conventional aircraft field than is the case in the higher performance area. The economics of the situation, and in the case of DOD, military need, eventually will determine how many individuals will seek each field. Recently increase emphasis in VTOL and STOL aircraft has insured funding for research in the lower speed areas and has attracted competent people. Assurance that the resolution of low-speed aircraft design optimization will take some time to accomplish is probably all that is necessary to insure a flow of people into the technological area.

In the field of aeronautical or astronautical engineering, as I indicated more generally in my answer to the previous question, the secret of success for any technical man is a broadly based scientific and technical education, which permits him to move rapidly in response to the challenge of new problem areas. Well-trained people will be able to move into a new area to a degree determined by how challenging the area is to them and whether the material rewards offered by it justify the move.

11. From the standpoint of objectives, program content and management, which of NSF's programs do you consider to be the best, and which do you consider to be the least useful.

(a) What are NSF's notable weaknesses or deficiencies, from DOD's point of view? How may they be corrected?

(b) In general, what more could the Foundation do to promote the progress of science?

11. I am not in a position to comment on the quality of any specific NSF programs, but I would like to make some general observations regarding the manner in which the NSF can best interact with and support the mission-oriented agencies such as the DOD.

First, I believe that each mission-oriented agency should support on a substantial level basic research which is relevant to its mission. In this manner, the Nation's basic research programs are most efficiently and naturally focused into areas of probable utility to the broad social missions of Government. Furthermore, because of the close coupling between the performer and the potential user, the likelihood of application is enhanced. Also, relevant basic research,

applied research and development are symbiotically related. Together, they form a powerful and indispensable tool for the accomplishment of the agency mission; fragmented and isolated, they become weak and inefficient.

Second, I believe that the NSF should perform the essential function of concentrating on supporting those areas of research which, for any reason or another, are not being adequately supported by the mission-oriented agencies.

Third, the NSF is well suited to taking the lead in building up new centers of excellence which can then compete on the basis of quality for the research dollars of the mission-oriented agencies.

Finally, there are many other functions concerned with the welfare of science, such as technical education, curriculum reform, manpower information, etc., which are best performed by a central agency such as NSF.

As far as I can judge, the NSF and the mission-oriented agencies have, up to the present time, worked together very much in the manner outlined above, and we in DOD would like to continue this way. I believe, however, that increased support to NSF would allow it to better perform its unique functions.

12. Regarding your prototype experiment called Project ILSE, which was mentioned in your statement, are you suggesting that it would be possible for a single group of specialists to analyze all the interagency research in a particular field, and then come up with a balanced program which would be acceptable to all the agencies concerned? How would you go about setting up such a program?

12. Project ILSE demonstrated that it is possible for qualified scientists from more than one Federal agency to review comprehensively the related research programs of each. With proper grouping of topics into disciplinary areas that are relevant to the specialized competences of the reviewing scientists, ILSE experience has established that such scientists can make intelligent decisions regarding duplication of effort, neglected avenues of research, desirable redundancy, etc., if they are provided with accurate abstracts of the research efforts pertinent to their fields.

The basic problem is to organize the available information into relevant and intelligible packages. This can be done easily by competent specialists in "information storage and retrieval" with the help of tapes and computers.

ILSE, in its earliest efforts, was not an overwhelming success, but the experience gained has developed ILSE into a truly workable system, the principles of which can now be applied to other disciplines. For instance, DOD and NASA are doing the same job in materials as we did in ILSE for life sciences. A committee has been set up to assemble and examine the materials projects. Since the dollar magnitudes of ILSE and materials are about the same, we expect to have about the same number of groups of experts examine the 4,000 to 5,000 projects of NASA and DOD and point out overlapping areas and gaps. The first step in any such effort is to be sure we are speaking the same language. Last year NASA and DOD agreed on a common condensed report form. NASA already has the content of these on tape and DOD will have theirs in the next few months.

Having achieved this common language facility and a modern storage retrieval system, we can now compare programs early in the fiscal year before they are too far advanced. In the past people have gone on the assumption that a listing of projects accomplished this purpose, but the resulting summaries were 12 to 18 months old and consequently became only bookshelf items. With rapid information exchange now possible, there is no reason that the same principle cannot be extended to other interagency programs.

13. You also mentioned that DOD provides the logistic support for the Antarctic research program and that DOD scientists participate in the program. Since DOD provides more than three times the amount of funds for this program that NSF does (since 1958, DOD $182 million, NSF $42.6 million) should DOD more properly be the agency to plan and coordinate the program?

13. Despite the difference in relative funding by the DOD and NSF, planning and coordination of the program are more properly accomplished by the NSF. It is the scientists who must control the research program. That agency responsible for the greatest number of scientists should dominate the program planning and coordinating activities. Most of the scientists involved in the program currently are from other than DOD. In view of the fact that the DOD-supported research in science and technology is primarily mission relevant, and in recognition of the limitations imposed by the Antarctic Treaty (copy attached) on the areas of research properly conducted in the Antarctic it is unlikely that any significant shift in the relative proportion of DOD to non-DOD scientists will occur.

The reason for heavy DOD fund commitment in the Antarctic is our unique capacity to provide logistic support. Severe logistic problems imposed by distance and weather are responsible for the high ratio of support costs to direct scientific costs.

By contrast with the case of the Antarctic, we think the DOD should take a leading role in the planning and coordination of research in the Arctic. Knowledge of extremely cold natural environments is highly relevant to the DOD mission, but in the strategically important Arctic, such knowledge can be obtained at far lower logistic cost than elsewhere. Also, the Arctic is an area of great military importance. Arctic research provides an example of a case in which the DOD is actively engaged in research and is taking the lead in both scientific programs and in logistic operations.

Text of Antarctic Treaty

The Governments of Argentina, Australia, Belgium, Chile, the French Republic, Japan, New Zealand, Norway, the Union of South Africa, the Union of Soviet Socialist Republics, the United Kingdom of Great Britain and Northern Ireland, and the United States of America.

Recognizing that it is in the interest of all mankind that Antarctica shall continue forever to be used exclusively for peaceful purposes and shall not become the scene or object of international discord;

Acknowledging the substantial contributions to scientific knowledge resulting from international cooperation in scientific investigation in Antarctica;

Convinced that the establishment of a firm foundation for the continuation and development of such cooperation on the basis of freedom of scientific investigation in Antarctica as applied during the International Geophysical Year accords with the interests of science and the progress of all mankind;

Convinced also that a treaty ensuring the use of Antarctica for peaceful purposes only and the continuance of international harmony in Antarctica will further the purposes and principles embodied in the Charter of the United Nations;

Have agreed as follows:

ARTICLE I

1. Antarctica shall be used for peaceful purposes only. There shall be prohibited, inter alia, any measures of a military nature, such as the establishment of military bases and fortifications, the carrying out of military maneuvers, as well as the testing of any type of weapons.

2. The present Treaty shall not prevent the use of military personnel or equipment for scientific research or for any other peaceful purpose.

ARTICLE II

Freedom of scientific investigation in Antarctica and cooperation toward that end, as applied during the International Geophysical Year, shall continue, subject to the provisions of the present Treaty.

ARTICLE IIII

1. In order to promote international cooperation in scientific investigation in Antarctica, as provided for in Article II of the present Treaty, the Contracting Parties agree that, to the greatest extent feasible and practicable:

(a) information regarding plans for scientific programs in Antarctica shall be exchanged to permit maximum economy and efficiency of operations;

(b) scientific personnel shall be exchanged in Antarctica between expeditions and stations;

(c) scientific observations and results from Antarctica shall be exchanged and made freely available.

2. In implementing this Article, every encouragement shall be given to the establishment of cooperative working relations with those Specialized Agencies of the United Nations and other international organizations having a scientific or technical interest in Antarctica.

ARTICLE IV

1. Nothing contained in the present Treaty shall be interpreted as:

(a) a renunciation by any Contracting Party of previously asserted rights of or claims to territorial sovereignty in Antarctica;

(b) a renunciation or diminution by any Contracting Party of any basis of claim to territorial sovereignty in Antarctica which it may have whether as a result of its activities or those of its nationals in Antarctica, or otherwise;

(c) prejudicing the position of any Contracting Party as regards its recognition or non-recognition of any State's right of or claim or basis of claim to territorial sovereignty in Antarctica.

2. No acts or activities taking place while the present Treaty is in force shall constitute a basis for asserting, supporting or denying a claim to territorial sovereignty in Antarctica or create any rights of sovereignty in Antarctica. No new claim, or enlargement of an existing claim, to territorial sovereignty in Antarctica shall be asserted while the present Treaty is in force.

ARTICLE V

1. Any nuclear explosions in Antarctica and the disposal there of radioactive waste material shall be prohibited.

2. In the event of the conclusion of international agreements concerning the use of nuclear energy, including nuclear explosions and the disposal of radioactive waste material, to which all of the Contracting Parties whose representatives are entitled to participate in the meetings provided for under Article XI are parties, the rules established under such agreements shall apply in Antarctica.

ARTICLE VI

The provisions of the present Treaty shall apply to the area south of 60° South Latitude, including all ice shelves, but nothing in the present Treaty shall prejudice or in any way affect the rights, or the exercise of the rights, of any State under international law with regard to the high seas within that area.

ARTICLE VII

1. In order to promote the objectives and ensure the observance of the provisions of the present Treaty, each Contracting Party whose representatives are entitled to participate in the meetings referred to in Article IX of the Treaty shall have the right to designate observers to carry out any inspection provided for by the present article. Observers shall be nationals of the Contracting Parties which designate them. The names of observers shall be communicated to every other Contracting Party having the right to designate observers, and like notice shall be given of the termination of their appointment.

2. Each observers designated in accordance with the provisions of paragraph 1 of this Article shall have complete freedom of access at any time to any or all areas of Antarctica.

3. All areas of Antarctica, including all stations, installations and equipment within those areas, and all ships and aircraft at points of discharging or embarking cargoes or personnel in Antarctica, shall be open at all times to inspection by any observers designated in accordance with paragraph 1 of this Article.

4. Aerial observation may be carried out at any time over any or all areas of Antarctica by any of the Contracting Parties having the right to designate observances.

5. Each Contracting Party shall, at the time when the present Treaty enters into force for it, inform the other Contracting Parties, and thereafter shall give them notice in advance, of

(a) all expeditions to and within Antarctica, on the part of its ships or nationals, and all expeditions to Antarctica organized in or proceeding from its territory;

(b) all stations in Antarctica occupied by its nationals; and

(c) any military personnel or equipment intended to be introduced by it into Antarctica subject to the conditions prescribed in paragraph 2 of Article I of the present Treaty.

ARTICLE VIII

1. In order to facilitate the exercise of their functions under the present Treaty, and without prejudice to the respective positions of the Contracting Parties relating to jurisdiction over all other persons in Antarctica, observers designated under paragraph 1 of Article VII and scientific personnel exchanged under subparagraph 1(b) of Article III of the Treaty, and members of the staffs accompanying any such persons, shall be subject only to the jurisdiction of the Contracting Party of which they are nationals in respect of all acts or omissions occurring while they are in Antarctica for the purpose of exercising their functions.

2. Without prejudice to the provisions of paragraph 1 of this Article, and pending the adoption of measures in pursuance of subparagraph 1(e) of Article IX, the Contracting Parties concerned in any case of dispute with regard to the exercise of jurisdiction in Antarctica shall immediately consult together with a view to reaching a mutually acceptable solution.

ARTICLE IX

1. Representatives of the Contracting Parties named in the preamble to the present Treaty shall meet at the City of Canberra within two months after the date of entry into force of the Treaty, and thereafter at suitable intervals and places, for the purpose of exchanging information, consulting together on matters of common interest pertaining to Antarctica, and formulating and considering, and recommending to their Governments, measures in furtherance of the principles and objectives of the Treaty, including measures regarding:

(a) use of Antarctica for peaceful purposes only;

(b) facilitation of scientific research in Antarctica;

(c) facilitation of international scientific cooperation in Antarctica;

(d) facilitation of the exercise of the rights of inspection provided for in Article VII of the Treaty;

(e) questions relating to the exercise of jurisdiction in Antarctica.

(f) preservation and conservation of living resources in Antarctica.

2. Each Contracting Party which has become a party of the present Treaty by accession under Article XIII shall be entitled to appoint representatives to participate in the meetings referred to in paragraph 1 of the present Article, during

such time as that Contracting Party demonstrates its interest in Antarctica by conducting substantial scientific research activity there, such as the establishment of a scientific station or the despatch of a scientific expedition.

3. Reports from the observers referred to in Article VII of the present Treaty shall be transmitted to the representatives of the Contracting Parties participating in the meetings referred to in paragraph 1 of the present Article.

4. The measures referred to in paragraph 1 of this Article shall become effective when approved by all the Contracting Parties whose representatives were entitled to participate in the meetings held to consider those measures.

5. Any or all of the rights established in the present Treaty may be exercised as from the date of entry into force of the Treaty whether or not any measures facilitating the exercise of such rights have been proposed, considered or approved as provided in this Article.

ARTICLE X

Each of the Contracting Parties undertakes to exert appropriate efforts, consistent with the Charter of the United Nations, to the end that no one engages in any activity in Antarctica contrary to the principles or purposes of the present Treaty.

ARTICLE XI

1. If any dispute arises between two or more of the Contracting Parties concerning the interpretation or application of the present Treaty, those Contracting Parties shall consult among themselves with a view to having the dispute resolved by negotiation, inquiry, mediation, conciliation, arbitration, judicial settlement or other peaceful means of their own choice.

2. Any dispute of this character not so resolved shall, with the consent, in each case, of all parties to the dispute, be referred to the International Court of Justice for settlement; but failure to reach agreement on reference to the International Court shall not absolve parties to the dispute from the responsibility of continuing to seek to resolve it by any of the various peaceful means referred to in paragraph 1 of this Article.

ARTICLE XII

1. (a) The present Treaty may be modified or amended at any time by unanimous agreement of the Contracting Parties whose representatives are entitled to participate in the meetings provided for under Article IX. Any such modification or amendment shall enter into force when the depositary Government has received notice from all such Contracting Parties that they have ratified it.

(b) Such modification or amendment shall thereafter enter into force as to any other Contracting Party when notice of ratification by it has been received by the depositary Government. Any such Contracting Party from which no notice of ratification is received within a period of two years from the date of entry into force of the modification or amendment in accordance with the provisions of subparagraph 1(a) of this Article shall be deemed to have withdrawn from the present Treaty on the date of the expiration of such period.

2. (a) If after the expiration of thirty years from the date of entry into force of the present Treaty, any of the Contracting Parties whose representatives are entitled to participate in the meetings provided for under Article IX so requests by a communication addressed to the depositary Government, a Conference of all the Contracting Parties shall be held as soon as practicable to review the operation of the Treaty.

(b) Any modification or amendment to the present Treaty which is approved at such a Conference by a majority of the Contracting Parties there represented, including a majority of those whose representatives are entitled to participate in the meetings provided for under Article IX, shall be communicated by the depositary Government to all the Contracting Parties immediately after the termination of the Conference and shall enter into force in accordance with the provisions of paragraph 1 of the present Article.

(c) If any such modification or amendment has not entered into force in accordance with the provisions of subparagraph 1(a) of this Article within a period of two years after the date of its communication to all the Contracting parties, any Contracting Party may at any time after the expiration of that period give notice to the depositary Government of its withdrawal from the present Treaty; and such withdrawal shall take effect two years after the receipts of the notice by the depositary Government.

ARTICLE XIII

1. The present Treaty shall be subject to ratification by the signatory States. It shall be open for accession by any State which is a Member of the United Nations, or by any other State which may be invited to accede to the Treaty with the consent of all the Contracting Parties whose representatives are entitled to participate in the meetings provided for under Article IX of the Treaty.

2. Ratification of or accession to the present Treaty shall be effected by each State in accordance with its constitutional processes.

3. Instruments of ratification and instruments of accession shall be deposited with the Government of the United States of America, hereby designated as the depositary Government.

4. The depositary Government shall inform all signatory and acceding States of the date of each deposit of an instrument of ratification or accession, and the date of entry into force of the Treaty and of any modification or amendment thereto.

5. Upon the deposit of instruments of ratification by all the signatory States, the present Treaty shall enter into force for those States and for Sates which have deposited instruments of accession. Thereafter the Treaty shall enter into force for any acceding State upon the deposit of its instrument of accession.

6. The present Treaty shall be registered by the depositary Government pursuant to Article 102 of the Charter of the United Nations.

ARTICLE XIV

The present Treaty, done in the English, French, Russian, and Spanish languages, each version being equally authentic, shall be deposited in the archives of the Government of the United States of America, which shall transmit duly certified copies thereof to the Governments of the signatory and acceding States.

IN WITNESS WHEREOF, the undersigned Plenipotentiaries, duly authorized, have signed the present Treaty.

DONE at Washington this first day of December, one thousand nine hundred and fifty-nine.

RESPONSE BY DR. GLENN T. SEABORG, CHAIRMAN, U.S. ATOMIC ENERGY COMMISSION TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

---

1. In your testimony on July 6 you said, "Research and teaching are closely related."

(a) On the basis of your experience both as a university professor and as a Government administrator, which do you consider more important to the National Science Foundation—the promotion of scientific research or the advancement of science education?

(b) To what extent should holders of NSF graduate fellowships or traineeships be induced or required to do some teaching before they receive their Ph. D's?

1. (*a*) Scientific research promotes scientific education; scientific education is basic to scientific research; in fact the two are indeed inseparable and interdependent. Therefore, regardless of relative funding levels I consider that there is no difference in importance with respect to promoting scientific research or advancing science education.

(*b*) I certainly believe that holders of any and all Federal fellowships should be encouraged to teach as part of their graduate programs, but only a specific university graduate department should require such teaching, not the Federal sponsor. The NSF fellowship literature states that NSF "shares the belief * * * that some experience in teaching contributes to the graduate training process" * * * and permits a fellow "to accept teaching opportunities * * * which will not retard the fellow's graduate training." AEC has similar provisions in its fellowship and traineeship program. Perhaps fellowship administrators could take a more positive approach in encouraging universities to develop appropriate teaching experiences for such fellows, and stress the desirability of this experience in the fellowship literature.

2. What is the anticipated trend within the Atomic Energy Commission concerning its support of basic research? How much of AEC's basic research can be considered to be mission oriented?

2. We expect that our overall research and development efforts will increase over the next decade, especially for basic research in the physical and life sciences. Increased funds will be required for support of new, large, costly experimental facilities and equipment. Such research increasingly depends on the use of more complex, and hence expensive, tools. Concomitantly, decreases in other parts of the AEC budget (e.g., raw materials procurement, production of special nuclear materials) are expected.

Section 31a of the Atomic Energy Act of 1954, as amended, provides for "a program of conducting, assisting, and fostering research and

development in order to encourage maximum scientific and industrial progress;". Further, "The Commission is directed to exercise its powers in such a manner as to insure the continued conduct of research and development and training activities in fields specified below * * * and to assist in the acquisition of an ever-expanding fund of theoretical and practical knowledge in such fields." Clearly, therefore, AEC has broad authority to conduct basic research relating to "nuclear processes * * *, the theory and production of atomic energy * * *, utilization of special nuclear material and radioactive material for medical, biological, agricultural, health, or military purposes; * * *." We thus consider that the conduct of basic research in the specified fields is part of our mission. In addition, we conduct basic research in fields such as oceanography and meteorology to support our applied research, developmental, and production missions. There are, of course, differences in the relationships between certain phases of our basic research mission and our applied research and developmental missions. For example, the results of high energy physics research are, in general, not as immediately applicable to our applied missions as would, for example, be the results of some of our basic metallurgical research. However, on the foregoing premise, we consider that all of our basic research is mission oriented in that it either is part of our basic mission or is necessary to carry out our basic mission.

3. To what extent do you think NSF should sponsor basic research of primary interest to mission-oriented agencies?

3. The mission-oriented agencies draw upon the whole base of scientific knowledge. Because of this and because the interests of the mission-oriented agencies change, I believe the NSF should continue to support meritorious research proposals independent of their current relation to the mission of another agency. On the other hand, the mission-oriented agencies cannot turn over their responsibilities to the NSF. They must continue to give emphasis to those areas of science bearing on their missions, and to exploit pertinent breakthroughs occurring in unrecognized fields, in order to achieve maximum progress. This diversity of support has been one of the main reasons for the strong position of the United States in the field of basic research, in my judgment. Of course, such diverse support requires good coordination among the agencies, which, as I have indicated in the past, does exist.

4. In the light of AEC's extensive experience in financing basic research, is it realistic to call for a 15-percent annual increase in NSF's basic research budget? Where would the undergraduates come from to provide an annual increase in the number of graduate science students? Could graduate schools expand continually without sacrificing quality of facilities, faculty, and education?

4.(*a*) Yes, because a 15-percent funding increase would just barely keep the program abreast of rising costs and anticipated graduate enrollment.

(*b*) College and university enrollments are rapidly increasing, currently at a faster rate than the population increases in the college-age population. The anticipated higher percentages of undergraduates going on for graduate study, as well as the increasing percentages of high school graduates going on to college should require the pro-

jected funding increase in order to provide for the anticipated increase in graduate students.

(*c*) I believe that the existing graduate schools of the country can absorb on an overall basis, a 15-percent annual increase in basic research funds without deleterious effect on the quality of their faculty or their facilities, at least for some time to come. This belief of course presupposes that adequate funds are made available to the institutions for library facilities, for courses and faculty in both the sciences and the arts and humanities, and for all the other vast complex that makes up an institution of higher education. If your question of continuing increase in size is related to any given campus, I suggest that there may be an optimum size beyond which further expansion may very well be deleterious. The above means that the Nation must provide support for increasing numbers of centers of excellence in order to effectively utilize the projected 15-percent annual increase.

5. With respect to science education in general, should more or less effort be expended by the mission-oriented agencies in its support?

5. I believe that mission-oriented agencies should increase their current levels of support for science education. This does not mean the effort should be made at the expense of an agency's specialized mission, but it does mean that the agencies must be very alert in using their resources of money, facilities, and scientific talent for the maximum benefit of science education as contrasted to restricting such "spin off" solely to very narrow specialized disciplines.

6. In supporting science education over the humanities or one field of science more than another, does the Federal Government incur an implied obligation to provide employment in the future for those graduates which it has supported? Do the students incur any implied obligation to stay in the field or to work on federally funded programs?

6. (*a*) There is no direct employment obligation incurred by the Federal Government, nor do I believe there should be. However, the various Federal agencies supporting either broad or narrow educational assistance programs do have an obligation to the taxpayers and to the recipients that the educational program will provide reasonable economic benefits to the recipient and to the Nation. For the individual this is obviously related to employment opportunity. For this reason, I believe that the projected increases in federally supported fellowships must be accompanied by sufficient research funds to provide the meaningful thesis research expecience necessary to assure that the fellow is adequately prepared for future employment opportunities. These opportunities, I am confident, will come because of the very nature of the scientific and technological revolution we are experiencing.

(*b*) Unless the Government is willing to guarantee employment it should not impose specific employment commitment upon the individual recipient. I suggest the best approach for mission-oriented agencies is that currently in use in AEC fellowships which use the language "The fellowships in * * * are limited to the support of those fellows who intend to remain within the field of the followship following completion of tenure." Incidently, though this referenced wording is relatively new in AEC fellowship literature, you may be interested to know that as of October 1964, 84 percent of all individuals who had

previously held AEC fellowships were still within the field of the fellowship. I consider this a phenomenal record.

7. Please explain more fully your statement to the committee that "nuclear reactors on the university campus may be utilized both for teaching and research."

(a) Do you mean simultaneously or separately?

(b) As a practical matter, what proportion of graduate science students at a university that is engaged in basic nuclear engineering research actually contribute to or participate in such research—as distinguished from experimenting with the low-power "teaching reactors" which you described?

(c) Do all professors engaged in nuclear research also teach classes, as you did?

7. (*a*) I mean both simultaneously and separately; with respect to those reactors that are not designed primarily for research purposes, the teaching use will predominate; with respect to those reactors designed for conduct of research, most of the research will be done with use of graduate students, and thus will facilitate both research and education. This demonstrates once again that graduate education and research are inseparable.

(*b*) A recent survey of university reactor utilization indicated the following: (1) Reactors of less than 10 kilowatts, frequently referred to somewhat erroneously as "teaching reactors" have been used for less than 25 percent of their operating time in research; (2) reactors of power levels up through and including 100 kilowatts are used equally for research and "teaching"; (3) "research reactors," those with power levels significantly higher than 100 kilowatts, have approximately 85 percent of their operating time devoted to research.

(NOTE.—Research utilization as shown above includes thesis research by graduate students, an example of truly "educational" reactor use.)

Statistics are not available as to numbers of students actually using reactors in laboratory courses versus those using them for research. Even in the case of 85 percent utilization for research, it is entirely possible that more individual students participate in the laboratory course use than in the research use, since research is usually an individual operation whereas courses involve a number of students.

(*c*) No. However, I believe that essentially all university faculty should perform both teaching and research duties.

8. To what degree do scientists and engineers drift away from their professional vocations into other fields—such as management, trade or commerce, finance or other business? Is this good or bad? What can be done to improve career counseling? At what educational level?

8. (*a*) University graduates in all fields do often leave the relatively narrow confines of their particular specialty, moving into a wide variety of positions which have some relationship to their own training. I have heard that approximately 50 percent of all engineering graduates do not become professional engineers; and in recent years the fields of management and sales increasingly have recruited engineers, and to some extent scientists, because of their special training.

(*b*) Widespread utilization of scientific and engineering talent in fields other than their own specialty is good for the Nation. The organizations for whom they work, as well as the individuals themselves, benefit from broadened views which lead to new insights and approaches to problems affecting business, education, and government.

51-204—65—vol. II——22

(*c*) I believe that career counseling must be strengthened at both the secondary school and the college level in order that each individual may be adequately advised as to the various educational paths that will enable him (or her) to make the greatest use of his own intellectual capabilities. The U.S. Office of Education has sponsored summer programs for secondary school counselors; I suggest this be expanded. College faculty, especially at the undergraduate level, should also be involved to a greater extent in guiding students toward the broadest possible education as well as toward an appropriate degree of specialization. I would warn against concentrating upon the sciences; adequate attention should also be paid to all academic disciplines, to careers in teaching, in government, in social work in the broadest sense.

9. You suggested that NSF step up support for additional educational opportunities for both students and teachers. How much should NSF's programs be boosted in this regard?

9. I do not recall any specific comment I made regarding increased financial support for students and teachers, as distinct from a general concept of increased financial support for the entire gamut of NSF science education and research support programs. We do not have the detailed familiarity with specific NSF programs to give a categorical answer in terms of funding level for any particular item.

However, I would suggest a significant increase in the efforts to involve undergraduate students and faculty, especially from the smaller colleges, in ongoing research activities of the Nation's universities, and of Federal facilities. I would increase the number of working conferences in which college and university faculty can explore the significance of scientific and technological development upon science curriculums in higher education, and can design new curriculums.

10. Are you satisfied with the ratio of NSF funding in regard to project grants versus institutional grants?

10. I do not have enough detailed data on which to formulate an opinion on the very specific question posed. However, as stated in my prepared testimony, I believe NSF should receive additional funds for support of the highest quality research (project grants), for support of research at less well-known institutions (presumably through project grants) and for the institutional base grants and science development grants programs. The institutional grant programs require additional funds in order to develop additional centers of excellence, to increase the Nation's output of scientifically trained people and to permit the institutions reasonable flexibility in the use of funds. Project grant support requires further increase to allow the Nation to support those capable of conducting good research, to add to our fund of basic knowledge and to assist in the training of graduate students. A more rapid increase in the institutional grant program support is desirable but will also require a more rapid rate of increase for project grant support at the time the institutional grant recipients are ready to submit (additional) requests for project grant support. Under no circumstances should increased funds for institutional grants be provided at the expense of project grant support.

11. The AEC plans to support 372 predoctoral fellows in fiscal year 1966, contrasted with 8,040 by NSF, 3,646 by NASA, and 4,000

by NIH. In view of the relatively small number supported by AEC, should this program be absorbed by NSF?

11. (*a*) I believe that numbers alone are never the sole measure of the need to support separate mission efforts.

(*b*) I strongly believe that the AEC must continue its separate fellowship and traineeship activities. Our traineeships emphasize nuclear engineering and are available at campuses where we have very close and continuing contacts. The AEC special fellowships in health physics require fellows to spend 3 months at an AEC laboratory site gaining actual experience in utilizing their education. The AEC laboratory graduate fellowships provide opportunities for M.S. and Ph. D. thesis work using very specialized facilities under the guidance of the specialized scientific staff members of AEC contractors. I believe these special features justify continued AEC administration despite, or perhaps because of, the relatively small proportion of total Federal fellowships involved. I suggest that it is illogical to expect NSF adequately to administer these specialized activities which use AEC facilities and staff.

12. In your book, "Education and the Atom," you describe how the Florida State University, the Public Health Service, and the AEC worked together to establish a new center of excellence in molecular biology at Tallahassee. This was in 1959, before the Foundation began its science development program. Do you see future possibilities for similar interagency collaboration? What should be the role of the Foundation concerning such ventures?

12. Yes; there are many possibilities for more interagency collaboration. This is especially true for mission-oriented agencies which may have overlapping interests such as the U.S. Public Health Service and the Atomic Energy Commission. These agencies are already developing programs of joint interest in the fields of radiation carcinogenesis and centrifuge development at the Oak Ridge National Laboratory. Since the NSF has the broad field of basic science as its concern, there is overlap of interest with several mission-oriented agencies. However, the NSF is not an operating agency and does not normally have specific requirements to meet that on occasion might better be developed in concert with another agency. In the future, however, such requirements may very well develop.

Another example of interagency collaboration in the development of centers of excellence is the interdisciplinary materials research program which is just now reaching fruition. In this case the agencies working together through the Federal Council for Science and Technology developed a plan to assist universities to build new laboratories, acquire modern expensive equipment, develop central service facilities, and expand their graduate research programs for the purpose of increasing the production rate of trained manpower in the materials-related sciences. Several of these new laboratories will go into operation this year. In most instances, all of the agencies support individual projects within the complex, each of which is able to proceed more efficiently because of the "core" facilities provided by the sponsoring agency.

I foresee the possibility of many such collaborative efforts in the future. Generally speaking, the mission-oriented agencies support research where there is demonstrated capability and the research can be

judged a mission-related. This is largely true, although not completely, of AEC, even though we have a basic research mission in specified fields, as explained in the answer to question 2. Therefore, the aid in development of the initial capability and the support to attract the initial cadre of scientists usually is more properly the role of the NSF rather than the mission-oriented agency.

It is clear that joint efforts by NSF and other agencies working in concert could do much to speed up the development of new centers of excellence, perhaps by NSF providing grants for initiation of building programs and furnishing basic equipment while other agencies support continuing programs in the same institutions in the areas of their responsibility.

13. With respect to the future utilization of AEC laboratories, do you foresee that they will continue to be fully utilized with the atomic energy program? Might your special facilities and equipment be used for other basic research? If so, what would be the appropriate role for NSF in arranging for such use?

13. We believe that our laboratories can be fully utilized within the atomic energy program for many, many years. They are fully occupied now; and there are many tasks to be undertaken should specific activities now being carried on diminish in importance or requirement. However, this does not mean that our special facilities and equipment cannot be used for other basic research. In fact, they are. An appreciable amount of research is conducted for other agencies at the AEC laboratories, some of it in nuclear fields, some of it nonnuclear, and some of it on a cooperative basis such as the cocarcinogenesis program at ORNL. This is jointly sponsored by AEC and NIH.

We will continue to make available to other agencies our specialized facilities and capabilities to the fullest extent possible, consistent with the satisfaction of AEC needs and the lack of availability of equivalent services in the private economy. Because mechanisms for arranging for their use are already available, we see no special overriding role for NSF for this purpose. We would participate with NSF in arranging for such use where mutual interest and advantage exists. Of course, individual facilities at any of our laboratories can become surplus to the specific mission for which they were originally intended. In these cases, AEC would gladly make them available to other Federal agencies, or to colleges and universities, and would welcome their use by such parties, assuming appropriate financial arrangements can be made.

14. Do the major AEC laboratories, such as Argonne and Brookhaven, serve as national resources in the same sense as the NSF national research centers through their availability to qualified scientists without regard to organizational affiliation? What is the AEC policy with respect to visiting scientists at its laboratories? What is the precentage of time that facilities can be used for research by such scientists?

14. Yes, the major AEC laboratories serve very much as a national resource, particularly in the basic research area, and are made available to qualified scientists without regard to their affiliation. Of course, we want to assure that they are used primarily for the purpose for which they were established; namely, research and development in the nuclear fields; and in these fields we want to assure that sci-

entific merit governs their availability. This is particularly true of our high-energy physics facilities, although the concept does not stop there.

For example, each of the major laboratories has a variety of programs wherein specialized facilities are made available to scientists from other organizations on a collaborative or a guest basis. In these cases, qualified scientists may join the laboratory staff on a salaried or nonsalaried status, depending upon the particular situation, for periods of a year or more, or they may make intermittent use of specific facilities for individual experiments.

Examples of other programs include (*a*) summer participation programs wherein university professors, and in some cases high school teachers, come to the laboratories to participate in ongoing research projects (*b*) graduate student fellowship programs where the student carries out his thesis research at one of our laboratories after completing the other requirements for his degree; (*c*) traveling lecture programs where at our expense our scientists travel to participating universities to deliver lectures and conduct symposia. Such programs were initiated many years ago at some of our multiprogram laboratories but have now been extended to other AEC installations such as the National Reactor Testing Station in Idaho, the Pacific Northwest Laboratory in Richland, Wash., and the Savannah River Laboratory in Aiken, S.C. We are encouraging these installations to expand their cooperation with nearby university faculty and their students in providing opportunities for research and training which are mutually beneficial to the AEC and to the educational institutions, their faculty, and students.

From these few examples it is clear that our facilities are used for both research and educational purposes, and that our major laboratories are indeed national resources. Rather than speak about the percentage utilization of a laboratory as a whole by outsiders, it is perhaps more meaningful to think about individual facilities. Even so, I can state that at the present time the scientific staff of the Brookhaven National Laboratory is composed of almost equal numbers of permanent employees and of visitors. Obviously this is an unusual case and the overall percentage utilization by outsiders at our other laboratories is substantially lower.

Our high-energy physics installations find a high degree of utilization by "users groups" not directly connected with the prime installation. It is interesting to note that the high-energy physics facilities at Brookhaven are utilized at the present time to the extent of 70 percent by outsiders. Argonne Naional Laboratory has a collaborative arrangement with the midwestern university community to make available its neutron diffraction facilities to outside users up to 25 percent of the time—specific requests being reviewed by a board of experts composed of laboratory and university scientists. I could cite many more examples referring to our reactors, low-temperature facilities, engineering facilities, and other high-energy physics facilities, to name a few.

15. In your prepared statement, you said that the AEC finances proposals for research only on the basis of scientific merit. Previous testimony revealed that the Department of Defense frequently awards research contracts on proposals in which the technical, administrative,

and management criteria between several contractors are very close and difficult to decide.

(*a*) *Is this true also in AEC's selection of contractors? If not, what criteria does AEC use in order to make the selection between the top several contractors strictly on merit, and how do they differ from DOD's criteria?*

(*b*) *If a selection between the top several contractors is difficult to make, do you consider geographic consideration to be appropriate? If inappropriate, why?*

(*c*) *Has AEC utilized geographic consideration in the past in selecting research contractors, or does it plan to do so in the future?*

15. (*a*) The overriding consideration in the award of contracts for research is the scientific merit of the proposed work coupled with the capabilities of the principal investigator(s) and the facilities available to him. In the award of contracts for development activities involving hardware development, construction of facilities, close integration with work at other contractor sites, etc. (such work constitutes the large fraction of DOD activities) and in the award of contracts for operating major Government-owned facilities, the administrative and managerial capabilities of the proposer are important factors to be considered in the award of a contract. Generally, for the same type of effort, AEC and DOD criteria are similar—all the factors which have a bearing on which organization can best perform the job in question are considered and carefully weighed in arriving at a decision.

(*b*) We consider that we have a good geographic spread in the location of our basic research contracts with universities and in the location of our Government-owned laboratories and research centers. We do feel that it is highly desirable to maintain AEC's existing major laboratories and plants as strong centers to carry out AEC's mission and, as such, utilize their facilities and highly capable personnel to perform a significant fraction of the AEC's R. & D. activities.

However, with respect to selection of research and development contracts for work in commercial facilities, AEC has the following policy, published in atomic energy procurement regulations 9–56.404: "In selecting recipients of research and development work, it is basic AEC policy to assign the work where it can be done most efficiently and effectively. Where it is otherwise appropriate to assign the work to a commercial concern, it is also the policy of the AEC to make such wide distribution of contract awards as will encourage broad participation by qualified research and development contractors performing work in their own facilities in order to (*a*) maintain a competitive industrial base; and (*b*) prevent firms from attaining a predominant position in a major segment of the atomic energy industry."

We have no specific policy statements on the matter of geographical considerations in the award of contracts, beyond the one cited above. Although geographical distribution as such is not a primary consideration in awarding AEC research and development contracts, we clearly recognize the significance such awards can have for certain regions. As a result, one of our objectives has been to bring about a more widespread participation in the atomic energy program although our main objective always is to accomplish best whatever particular task must be performed. When these two objectives are incompatible, the former must of necessity give way to the latter.

Therefore, I am inclined to answer your specific question by saying that if other things truly are relatively equal among several top contractors and the choice is therefore difficult to make, geographic consideration would be one factor that could appropriately be applied. My concern is that other things are too infrequently, if ever, relatively equal. Thus, a strong policy along the lines indicated could lead to the undesirable substitution of political geographical judgments for objective standards of excellence in the apportionment of research and development funds.

(c) Through natural processes we believe that we have attained a reasonable geographic distribution of our research contracts. We have no plans specifically to utilize geographic considerations in the selection of research contractors beyond the application of the policy statement quoted above.

16. As a former member of the National Science Foundation Board, how would you compare it with the Atomic Energy Commission with respect to its authority, functions, responsibilities, and agency operations?

16. The National Science Board, consisting of 24 members, is the policymaking body of the NSF, and meets approximately 9 times a year. The Board must either approve, or delegate authority to its Executive Committee or to the Director to approve fellowships and grants or contracts for basic scientific research activities. The Board is clearly not a day-to-day operating body. The main activities of the NSF are the support of basic research in the physical sciences, engineering, mathematics, biological, medical, and social sciences; funding education in these sciences and fostering interchange of scientific information; providing a clearinghouse of information on U.S. scientific and technical personnel; and development of studies related to planning of national science policy.

The Atomic Energy Commission, in addition to conducting basic research programs and education and training activities, and fostering scientific information interchange, is responsible for raw materials procurement and processing, a large effort on the production of special nuclear materials, the development and manufacture of nuclear weapons to meet all military requirements, and the development of applications and utilization of atomic energy, for electric power, propulsion, space exploration, and industrial, research, medical, and other purposes. The Commission is also responsible for regulating private possession and use of reactors and nuclear materials in the United States.

The responsibility for all these activities rests with the five Commissioners. They serve full time and are responsible for policymaking and for oversight of the day-to-day activities of the agency.

17. What is the AEC's response to the Federal Council for Science and Technology interim report for 1963, which states that no usable data were obtained from Federal agencies in an effort to develop projections of agency requirements for funds through 1970?

17. The data submitted by the Atomic Energy Commission and used in connection with the preparation of the Federal Council's interim report for 1963 were derived from our internal planning documents. Such data have been most useful for internal management purposes including the longer range formulation of the Commission's research and development programs and the preparation of budgets, and budget

projections. The data furnished also were fully responsive to the request made by the Federal Council and we believe that the Council's Long Range Planning Committee considered the AEC's response to be a competent submission.

The Federal Council report stated that "this effort did not result in usable data . . . ." This finding is related to the question of whether consolidation of individual agency plans for a relatively short period—10 years, 1961 to 1970—is an adequate or even valid base for developing broad national goals for research and development.

The Federal Council has found that the concept of Government-wide long-range planning is complex and much more work will have to be done before the problems, including those revealed in the initial study, are resolved. The data furnished by the agencies helped in identifying the scope and nature of the problem, and to that extent may have been useful and well worth the effort.

18. Exactly how does the AEC make use of the Science Information Exchange?

18. The Science Information Exchange provides information which is an integral and routine part of the AEC's procedure for evaluating and processing research proposals. When a proposal is processed, information is provided by SIE on the support the investigator receives from all Federal sources reporting to the Exchange. This material covers past support, present support and insofar as possible gives the amount for pending proposals in the name of the investigator and his principal assistants whose names appear on the proposal.

When support is granted the investigator provides an abstract of his contemplated work to SIE. This is the source of information which then becomes available to other Federal agencies that make use of the Exchange.

The Exchange can by use of these abstracts provide answers to questions concerning the extent of research being supported in various areas of science. The AEC research administrators make frequent use of this capability to insure that unnecessary duplication of effort is avoided and to insure that an area basic to AEC's responsibilities is not being neglected.

19. The point has been brought out during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency X, agency Y, or both. More specifically:

> *(a) What guidelines or criteria has the AEC established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the agency's jurisdiction and, therefore, should, or should not, be supported by the agency?*
>
> *(b) If written criteria have been established by AEC, please submit a copy thereof to the committee.*

19. (a) The budget categories and the statements of functions and delegations of the various divisions of the AEC detail the areas of research which are appropriate for support by the AEC. These in turn are based on section 31 of the Atomic Energy Act, to which I referred in the answer to question 2. In addition, the many years of experience by AEC in conducting its research gives us a competent and

sophisticated scientific staff that really has no trouble in arriving at appropriate judgments with respect to suitability of a proposal for AEC support.

Upon receipt of a proposal from a university, the appropriate AEC scientist or engineer reviews the subject matter of the proposal in the light of these guidelines. If it is found to be outside the purview of the AEC, it is suggested to the proposer that he seek support from a more appropriate agency. As is more often the case, if the proposal has been submitted to several agencies, two or more may find the research of interest to them. In these instances, the research administrators, after carrying out their individual evaluations, discuss the proposal in terms of relative interest in each of the agencies and the capability by each agency to support the proposal, as well as other administrative matters. At these informal discussions, a decision is reached as to which agency will provide the requested support.

As I stated in my testimony before this committee on July 6 we have not had an unresolved jurisdictional problem. It is a fact that we have many more requests for support of meritorious research than we are able to satisfy, and as a consequence, it is never a matter of dispute as to which agency will take the responsibility, rather it is a matter of sharing the overall responsibility and seeing that the most worthy proposals receive support.

(*b*) We do not really have written criteria covering specifically the question raised. We do have budget categories, as well as functional statements, covering the activities of our scientific divisions. However, it is my impression that this sort of material is not what you really want. If you do want this material, we can readily give it to you.

20. In your speeches in recent years, you have called attention to problems of technological obsolescence of manpower. What future role do you see for the Foundation in studying and sponsoring means to retrain and reeducate scientists and engineers to extend their useful work life? What effect would this have on supply of scientists and engineers for new work?

20. The need for continuing education as well as reeducation is increasing every year, due to our changing society in general and to our rapid scientific and technological development in particular.

(*a*) It should be noted that the wide variety of NSF programs for helping to create better teachers through faculty institutes, conferences, and faculty fellowships are a combination of continuing education and retraining for scientists and engineers whose major responsibilities are teaching and research. Thus NSF already does have an active role in retraining and reeducation so that individuals may have greater capabilities for a useful work life.

(*b*) I suggest that NSF should broaden the foregoing activities to examine the current needs for continuing education and retraining of engineers, scientists, and technicians, and to examine the many current innovations being adopted by some segments of industry, by those conducting adult education, and by the foundations working with specific universities. Such an overall study is now overdue, and I believe NSF is in the best position to make this broad overview. As a result of the study, I would anticipate that NSF might find it advisable to sponsor conferences and institutes for individuals from the universities, from

industry and from Government to design a variety of programs that might then be incorporated in the Nation's total educational system. Funding of regional continuing education centers might be an appropriate function of NSF in addition to those private foundations already working on such studies.

Such a program should include cooperative programs with the Department of Health, Education, and Welfare, the Department of Labor, the Office of Science and Technology and the State educational systems that sponsor community college programs. The specialized agencies can also help; for example, the entire atomic energy program required a great deal of retraining of manpower, especially in the earlier days.

21. From the standpoint of objectives, program content and management, which of NSF's programs do you consider to be the best, and which do you consider to be the poorest?

(a) What are NSF's notable weaknesses or deficiencies, and how may they be corrected?

(b) What additional objectives or programs do you think the Foundation might undertake to promote the advancement of science?

21. (*a*) NSF's principal weaknesses and deficiencies stem from a lack of sufficient funds to support their objectives and responsibilities. Limitations on time and manpower at the AEC as well as lack of detailed knowledge of NSF activities do not permit a detailed balanced review of all of the functions and activities of the NSF. Thus, I believe it inappropriate to make a statement on which is best and which is the poorest or to attempt to point out notable weaknesses.

I do wish to make another point, which, however, should not be considered a criticism—rather an observation. It must be recognized that there are certain types of projects which the National Science Foundation may not be adequately equipped to handle at the present time. Of course I am referring to the very large projects such as that exemplified by the 200 Bev. high-energy particle accelerator. To manage programs of this sort properly, an agency must have experience and depth in construction, procurement, practical engineering, legal, and fiscal matters.

The AEC inherited an extensive management capability from the Manhattan Engineer District and thus at its inception was equipped to handle very large projects. The National Science Foundation in its short span of life has developed managerial and scientific capability in a praiseworthy fashion. If the National Science Foundation is expected to have the capability for all programs that might come within its charter of responsibility, it should be provided with additional inhouse technical and administrative capability.

(*b*) I do suggest that in the whole area of education, not merely science education, the Federal Government, especially the National Science Foundation and the U.S. Office of Education, should take a more positive stand of leadership to correct the many educational deficiencies that were so well pointed out during the White House Conference on Education.

I specifically suggest that NSF along with the Office of Education develop a coordinated approach to secondary school science curriculums, avoiding the current emphasis on specific science courses.

A more active program is needed to alter collegiate undergraduate science and math curriculums to reflect the changes already made in high school curriculums in the same subjects. Too often the entering freshman from a good high school program is finding himself repeating his work, perhaps even at a lower level.

I would suggest that NSF consider turning over its elementary school science education efforts to the Office of Education, at least the direct financial support aspects; and then act in the role of science consultant to the USOE.

I suggest NSF should take a more active role in encouraging joint programs among educational institutions, especially between a small college and a university.

Support for engineering research including nuclear engineering research should be greatly increased as a recognition of the role engineers can and should play in helping solve many of our national and international problems such as water supply, air pollution, transportation, food production from crop growing through adequate distribution to the ultimate consumer, power production, etc.

22. Based on your own experience in the AEC with educating the public about atomic energy, what future role would you see for the Foundation in educating the public about the nature of this scientific age? What approaches do you think would be the most effective?

22. I suggest NSF should examine its current activities, especially those aimed at the general public as contrasted to those aimed at the scientists. A few possibilities are:

(*a*) A serious attempt to explain to the public the ultimate benefit to society from scientific and technological developments, in language for the layman. Major programs such as atomic energy, oceanography, high energy physics and the space program could all be explained in more day-to-day terms than at present. Too often one has the feeling that the literature of the individual specialized agencies is designed to sell their particular products, without demonstrating the overall national interest and benefit in all types of scientific progress.

(*b*) Better literature on the opportunities for careers in science and engineering, both for the professional and for the technician is needed. Here again, too often literature is designed for a single specialty, or a single agency. In addition, the role of the sciences and engineering in service to humanity never shines through.

(*c*) Several times during the recent President's Conference on Education the need for more study on the history of science was stressed. The NSF should encourage the writing of books and the dissemination of knowledge on this subject. The interrelationship of this topic with items (*a*) and (*b*) is too obvious to comment upon further.

(*d*) All efforts should be devoted to the concept that we have a great need for scientists interested in the humanities as well as humanists interested in the scientists. Therefore, in addition to the literature efforts stressed above, I would recommend that NSF and USOE collaborate on conferences and institutes in which faculty from both the sciences and the humanities get together with people from business, industry, and government to exchange ideas on the nature of big science and its impact upon society as a whole. The AEC has already pioneered in this area with its institutes in Oak Ridge on humanistic studies in science.

RESPONSE BY DR. HUGH L. DRYDEN, DEPUTY ADMINISTRATOR, NATIONAL AERONAUTICS AND SPACE ADMINISTRATION, TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

1. Since post-Apollo plans are indefinite, and graduate students entering the NASA fellowship program will not emerge until after the peak of the lunar landing effort, what are the inferences and implications as to future Government support of space science in NASA's 1,000 Ph. D.'s per year program?

1. Although post-Apollo plans are not yet firm, any aeronautical or space activity in coming decades will certainly require numbers of highly trained scientists and engineers. The NASA training program was not designed to support the lunar landing effort alone. Its graduates will take part in—and, hopefully, lead—the future program of space and aeronautical science and engineering.

In addition, it is reasonable to assume that new industries will grow from the new technology of space research, and trained people will be needed to staff them. Twenty percent of the Ph. D.'s coming out of the NASA program to date have gone to work in industry.

The target of 1,000 Ph. D.'s per year constitutes NASA's fair share of the responsibility for continuously replenishing the country's trained manpower resources. The number of new trainees entering has leveled off as NASA's total budget has stabilized. An assumption that the United States will try to retain leadership in aeronautical and space science and engineering dictates a continuation of this program to produce highly trained people.

2. Following up your testimony of July 7, to what extent is NASA support of basic research in universities mission oriented? How does it differ, in individual programs, from similar grants sponsored by the National Science Foundation? Would an analysis of random samples from both agencies, other than the Whitford report on astronomy which you mentioned, reveal a characteristic difference?

2. Basic research supported by NASA in universities is expected to yield results which will further the objectives of NASA as set forth in the Aeronautics and Space Act of 1958. This does not mean that all research projects are aimed at specific pieces of hardware or scheduled flight operations. It merely means that NASA concentrates its research support in a region of general relevance to its mission. Accordingly, NASA supports a great deal of propulsion research and little oceanography. Its life science programs reflect much interest in gravitational effects and little in cancer detection.

It is the structure of the research program which is mission oriented, not the administration of each individual project. Examples may be found of NASA grants and NSF grants which are very similar in their general content but different in approach or objective.

3. The future of the Foundation may be changed by the proposal to give to it more responsibility for developing the application of science. If this were done, one aspect of the new responsibility most likely would relate to the NASA technology utilization program. What do you think would be a possible role for the Foundation in speeding the application of the results of federally sponsored research?

3. To effectively apply the results of federally sponsored research in areas, disciplines, industries, and endeavors other than the specific mission for which the research was undertaken demands an intimate knowledge of the science or technology involved as well as considerable familiarity with the problems and objectives of the potential user of the information.

Most investigators who have studied the technology transfer process have concluded that transfer is most effectively achieved when there is a "personal champion" of the technology—that the bridge between innovator and user cannot be built of paper alone. To form such a bridge the disseminating agency must be intimately familiar with the work that forms the basis of the new knowledge.

Agencies such as NASA are accumulating very valuable experience in the transfer process. But in NASA the major thrust has been in action programs with only limited study of the transfer process per se. A logical and useful role for the National Science Foundation in speeding the application of the results of federally sponsored research might lie in that agency's taking the lead in encouraging research aimed at improving understanding of the methods and mechanisms for transfer.

It might organize what is already known on the subject, devise ways of using the information held by the SIE and consider expanding its purview to include engineering and applications, or perhaps involve the combined resources of the National Academy of Sciences and the new National Academy of Engineering.

4. You suggested in your statement that NSF should take the lead in developing a broader base of scientific support, then you added that the mission oriented agencies must give prime consideration to the matter of competence."

> *(a) Does this mean that NASA gives no consideration at all to the geographical distribution of stipends?*
>
> *(b) How about the consideration of individual need—is a means test a factor with NASA in making a decision among applicants?*

4. NASA is very concerned about geographical distribution of extramural support. NASA has active predoctoral training grants at 142 institutions, in all 50 States. This is, however, evidence of NASA's attempt to recognize ability wherever it exists, rather than an attempt to distribute funds uniformly per square mile or per State. Geographically uniform distribution would be as patently unwise as concentration of the effort in a few schools. Some sections of the country have a number of very good universities clustered close together, while others have notoriously sparse academic concentration.

In the statement from earlier testimony, the emphasis is on the word "prime." The important point is that NASA cannot afford to subordinate the accomplishment of its primary objectives to the principle of uniform geographical distribution. As long as competence

remains a foremost criterion, wide geographical distribution of effort is considered valuable to NASA's program, and every effort is made to achieve it.

NASA training grant are made to universities, not to students. The institutions, which select the individual trainees, are not insensitive to the matter of need and would be encouraged to give consideration to relative means if confronted by groups of candidates with otherwise identical qualifications.

However, NASA does not apply a means test. The use of such a test as a qualifying criterion—unless every other training opportunity in the country, public and private, applied the same test—would place NASA at a disadvantage which the program would probably not survive, by placing poverty ahead of quality in the selection process.

5. Along the same line, regarding R. & D. contracting procedures, testimony has revealed that the Department of Defense frequently awards contracts at times when the technical, administrative, and management criteria between several contractors is very close and difficult to decide.

(a) Is this also true in NASA's selection of contractors? If not, what criteria does NASA use in order to make the selection between the top several contractors strictly on merit, and how do they differ from DOD's criteria?

(b) If the selection between the top several contractors is difficult to make, do you then consider geographic consideration to be appropriate? If inappropriate, why?

(c) Has NASA utilized geographic consideration in the past in its contracting procedures, or does it plan to do so in the future?

5. Following the intent and direction contained in the Armed Forces Procurement Act, as amended, 10 U.S.C. 2304, NASA conducts written or oral discussions with those companies which are in a "competitive range"; that is, those which are relatively close as revealed by the evaluation criteria. After such negotiations are completed, it is usually clear which company should be selected as contractor. If two or more companies were in virtually a tie position, the selecting authority would take into consideration the possibility of choosing the contractor which could mean spreading the industrial base and bringing into the program a company which had had few or no prior NASA contracts. Such companies are quite likely to be located in geographical areas which have not had a large amount of contracts.

Other considerations for the selection of a contractor between companies in a close competitive range, as outlined in (*a*) above, might be whether a company is a small business concern or located within a labor surplus area, or in an area which had not received a substantial portion of NASA contracts. All of these factors are considered appropriate and within the intent of NASA's statutory authority.

NASA has utilized geographical considerations in its contractor selection procedures where such locations were necessary, advantageous, or economically expedient. For instance, where contractor-fabricated items were so large that transportation by water was necessary, the location of a contractor's production facility adjacent to water transportation facilities was a criterion for contractor selection. Another example is whether the proximity of supply is a critical consideration, such as propellant storage where the propellant must be

available for use on short notice and where distant transportation would add to the cost.

6. What possibilities are there for cooperative support to develop new centers of excellence through joint arrangements between NASA in-house technical centers and NSF science development program recipients (i.e., Rice University-Manned Space Craft Center, Houston, or Case Institute-Western Reserve-Lewis Research Center, Cleveland)?

6. Two of the NSF science development program recipients are already involved in cooperative enterprises with nearby NASA research centers. Summer faculty fellowship programs have been conducted by Case Institute of Technology in cooperation with the Lewis Research Center, and by the University of Virginia (as a participant in the Virginia Associated Research Center) in cooperation with the Langley Research Center. These programs allow faculty participants to receive both advanced academic training and experience in current research of interest to NASA.

7. In your testimony on NASA's education grants, you said that funds "are made available to the universities with the stipulation that they be used to enhance graduate study in space science and technology." Is this support confined to research? Are the students selected by the universities permitted to teach? Is there a time limitation on their teaching?

7. Funds made available to the university for enhancing graduate study in space science and technology are not confined to research. These funds may be used for such items as—

(*a*) Faculty augmentation—bringing new professors aboard in space-related areas, visiting lecturers, and so forth.

(*b*) Course content improvement—developing new space-related courses or revising existing courses.

(*c*) Acquisition of specialized research equipment.

(*d*) Student travel in connection with trainees' research and study.

(*e*) Other innovative ideas developed by the university which would strengthen the graduate program in space-related areas.

NASA trainees are permitted to teach in those instances where teaching is a departmental requirement for all Ph. D. students. In these instances the student receives his regular stipend but receives no additional payment for teaching.

There is no formal time limit placed on such teaching but it should not ordinarily exceed the minimum teaching requirements as established by the institution.

8. You referred to the fact that NSF's support of quality manpower development is concentrated in postgraduate education. Yet you recognized that high quality graduate students come only via undergraduate production; and you recommend that the Foundation increase its attention to the undergraduate level. Does this recommendation apply also to NASA? If so, how do you propose to implement it?

8. NASA has increased its attention to the undergraduate situation but still does not devote major financial support to, having neither the charter nor the resources to deal with the total problem. Aid to undergraduate education, as such, is considered more appropriately the domain of the NSF and the Office of Education.

On a very modest and selective basis, NASA has experimented with the involvement of interested undergraduates in space-related research and summer institutes in space science and technology. These latter institutes at Columbia University, UCLA, the University of Miami, and California Institute of Technology, have provided 6-week periods of intensive training for gifted undergraduates from all over the Nation.

9. Is NASA supporting, through its fellowship program, any of the social sciences, including political science?

9. Of nearly 2,000 NASA predoctoral trainees, approximately 5 percent are working in the social sciences.

10. How does NASA coordinate its educational support with the National Institutes of Health, the Atomic Energy Commission, the Office of Education, and other Federal agencies that are concerned?

There is nothing I have to add to the discussion of this question beyond the statement contained on pages 13, 14, and 15 of my testimony and the questioning that went on following my testimony.

11. In supporting science education over the humanities or one field of science more than another, does the Federal Government incur an implied obligation to provide employment in the future for those graduates which it has supported? Do the students incur any implied obligation to stay in the field or to work on federally funded programs?

11. NASA does not require, as a condition of traineeship acceptance, any formal commitment by the student to either work in a particular discipline or future Government employment. Graduates are encouraged to engage in research and teaching in the university environment in order to propagate their own kind. A natural incentive to work in space-related fields is provided by the intensive training which a Ph. D. receives in the discipline of his choosing. The national space program will presumably prove challenging enough to attract its fair share of these people in future years. However, should some other endeavor of comparable scope and importance offer more appeal to a particular student, it would be most unwise to force him into another line of work on the basis of a commitment made 4 or 5 years earlier. Even more significantly, the prospect of indentured service at the most productive point in their careers would not appeal to the students of highest competence. These are the ones with no qualms as to their ability to compete in their specialty when they graduate. Any training program with a built-in bias against such highly motivated and confident students would undoubtedly exhibit a swift and irreversible deterioration in the overall caliber of its participants and quality of its output.

The Government does not incur an obligation to provide employment for graduates from the training program. More important, the kind of people who seek and get doctors' degrees in science or engineering are not the kind likely to constitute a future unemployment problem.

12. To what degree do graduate engineers and scientists drift away from their professional vocations into other fields—such as management, trade or commerce, finance, or other business? Is this good or bad? What can be done to improve career counseling?

12. Extensive statistical data are contained in the National Science Foundation report NSF 63–34, published in 1964. That report states,

for example, that in the 1950's about 37 percent of the graduates with bachelor's degrees in science and 85 percent of those with degrees in engineering ultimately entered the fields for which they were trained. This gives no clue, of course, to the number which enter the field and later leave.

Statistical information on particular disciplines may be obtained from such documents as "Physics: Education, Employment and Financial Support," a statistical handbook published in 1964 by the American Institute of Physics.

It is obvious that graduate scientists and engineers do move into other areas such as management. Their talents are frequently invaluable there, and some are better managers than scientists. The important consideration is that they should not be forced out of science or engineering by lack of opportunity.

13. With the advent of the space age the charge has been made that rapid development of space technology has drawn many of the best professors, practicing engineers, and students away from aeronautical engineering into the more intriguing and glamorous field of space engineering, research, and development.

(a) Is this true? and, if so, is it cause for concern?

(b) Is any program in existence or contemplated to assure a balanced input of graduate space scientists and aeronautical engineers in the scientific and technological communities?

13. It is certainly true that examples can be found of professors, engineers, and students who have moved from aeronautical engineering into space research activities. No field of science or engineering remains forever preeminent, and the fundamental reason for the shift of people often lies in the field itself, which may be worked out of stagnant. New fields arise which offer more challenge and more opportunity. One is always concerned when a field as important as aeronautics has important jobs to do and no one interested in doing them. However, one should be equally concerned over any attempt to constrain workers to an older field when a new field is rising. Both space scientists and aeronautical engineers are emanating from the NASA training program. If there are challenges and opportunities in aeronautical engineering good students will seize them.

There has been a downward trend in NASA's attraction of aeronautical and aerospace engineers relative to personnel trained in other disciplines. In April 1962, aeronautical or aerospace engineering was the highest degree of 981, or 14.2 percent of NASA's inhouse scientists and engineers in the aerospace technologies. During the 15 months ending September 30, 1962, 322 or 9.3 percent of the newly hired scientists and engineers had aeronautical or aerospace engineering as the highest degree. The corresponding figure for the subsequent 2 years ending September 30, 1964, was 299 or 7.4 percent.

Of approximately 7,500 scientists and engineers, hired between July 1961, and September 1964, only 84 were teaching professors in aeronautics or any other discipline at colleges and universities immediately prior to their employment by NASA.

The NASA program includes important continuing activities related to aeronautics and aeronautical engineering.

14. Does NASA have any program for attracting older professional people back to school in order to update their technical capabilities?

Are we possibly ignoring or wasting this technical manpower resource? In other words, do we have any program for reeducating older scientists and engineers whose early college training may be obsolete?

14. As part of an effort to insure the updating of skills by the continued training of scientists and engineers, NASA sponsors summer faculty fellowship programs, which are cooperative endeavors between universities and nearby NASA centers. Faculty members usually spend some time at the university in seminars and some at the research center actually engaged in research. In 1965, about 100 faculty members participated in 7 programs which were carried on jointly with 12 universities.

In order to provide biologists with new knowledge about the operational and engineering aspects of space flights, NASA sponsored a two-and-a-half-week program designed to bring 100 faculty and select graduate students to NASA's Wallops Station. The program was undertaken for NASA by the University of Virginia and briefings were given by Government, university, and industrial personnel.

Another activity sponsored by NASA and designed to update skills at the forefront of technology is NASA's resident research associateship program, which involves postdoctoral studies in space science and engineering. Under this program, about 70 postdoctoral or senior postdoctoral participants will come to one of the NASA centers in 1965 to pursue advanced study of special interest to NASA. It was designed to aid in the solution of contemporary problems, provide researchers with advanced knowledge, and to demonstrate new techniques.

In the 2-year period ending September 30, 1964, 36 newly hired scientists and engineers were over 55 years of age, and 195 were between 46 and 55 years of age. Age is not a bar to NASA employment.

15. Does the Science Information Exchange record NASA inhouse project information? Exactly how do you make use of the Science Information Exchange?

15. NASA has cooperated in the provision of input concerning research in progress since the Science Information Exchange was established. Figures compiled by the SIE indicated NASA furnished information on 793 research projects in fiscal year 1963; on 696 during fiscal year 1964; and 338 during the first half of fiscal year 1965.

Under the terms of the NASA–SIE arrangement, NASA provides its complete listings of research grants and contracts awarded. With this information in hand, SIE queries the research investigators directly for specific information relating to the work they are doing or plan to do.

A recent agreement between NASA and the Department of Defense to more effectively exchange information on current research and technology programs has resulted in a standard reporting form No. 1498, by both agencies to facilitate machine processing. Dr. Bisplinghoff advised the SIE on April 21, 1965, that his office will expand the coverage of NASA-sponsored work in the SIE information pool: that recognition must be given to the fact that a sizable proportion of the activity is in a category which does not lend itself to dissemination for a general audience; that, as a result of the NASA–DOD agreement to exchange information on research and technology pro-

grams, SIE will be provided information automatically in 1966; and that during the interim period the information will be reviewed manually in order to increase the coverage of NASA program in SIE files.

Use is made of SIE by program scientists in headquarters or centers who wish to know what work is going on in particular fields. It is used more often by investigators who need to know what other groups are working in their particular areas, and under whose sponsorship work is being conducted.

16. NASA is well known for its studies of scientific and technical manpower. To what extent have your studies or data collection about demand and supply of scientists and engineers for space work been changed or influenced by the Foundation?

16. The National Science Foundation has conducted studies and collected data on overall national scientific and technical manpower over a number of years. These studies have been concerned with the development and dissemination of information relating to scientific manpower resources, and they have been aimed at facilitating national decisions relative to strengthening the scientific effort of the Nation. The information developed in these studies has also served a wide variety of purposes throughout the Federal Government and in the private sector of the economy. In conducting these studies, the NSF has developed definitions and methodology, as well as analysis techniques, which facilitate the measurement and consideration of scientific manpower resources.

In recent years, the National Aeronautics and Space Administration has conducted studies to identify and assess the impact of its program upon national manpower resources, particularly upon scientific and engineering manpower. In conducting these studies, NASA has utilized the NSF definitions of "Scientists and Engineers" and "Research and Development" in order to insure compatibility of results. More significantly, in making our estimates of scientific and engineering employment generated by the NASA program, NASA has drawn much from the NSF data analyses and estimating techniques. Finally, once estimates of NASA manpower requirements have been developed, they have been related to the overall NSF estimates to determine the impact of the space program upon national resources.

17. The point has been brought out during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded say, by agency X, agency Y, or both. More specifically:

(a) What guidelines or criteria has NASA established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the agency's jurisdiction and, therefore, should, or should not, be supported by NASA?

(b) If written criteria have been established, please submit a copy thereof to the committee.

17. NASA project managers are guided by their total knowledge of their program objectives, specific progress toward those objectives, and work in existence elsewhere. Individual judgment plays a large part in

the selection of projects for support. In only a few fields, such as astronomy, have written guidelines been established to delineate NASA's area of support vis-a-vis that of NSF.

18. NASA and the Foundation, among other Government agencies, draw heavily upon the advice of the scientific community. It would be useful were you to compare the ways in which NASA and NSF obtain such imput for the shaping of your major scientific programs.

(a) In particular, how do you define this "scientific community"? Having done so, how does one know that the scientists consulted reliably represent the best in scientific thought?

(b) What paths are left open—formal or informal—for divergent views when your agency chooses to consult the scientific community?

18. For this purpose, "the scientific community" may be defined as the people who actually engage in or direct scientific research.

It is never possible to know *a priori* what represents "the best in scientific thought." What is best is simply what turns out to be nearest to fact, or physical reality, and this ultimate truth is an elusive thing. Scientific opinions are perhaps different from those in other areas, however, in that they can often be subjected to the test of experiment. Hence, an estimate of the reliability of a particular scientist usually involves appraisal of his past performance, his reputation in his field, the breadth and depth of his experience, and his perception of the immediate problem.

Scientists thrive on diversity of view. Any attempt to suppress divergent opinions is probably less successful in the scientific community than any other. Free discourse is encouraged, and NASA tries to get various viewpoints on every important issue. Scientific dissenters are not usually reluctant to express disagreement, however, and if formal channels do not satisfy them, they seldom hesitate to argue their points with their colleagues, present them voluntarily to the agency, or publish them in the open literature.

Response by Dr. Don K. Price, Dean, Graduate School of Public Administration, Harvard University, to Questions of the Subcommittee on Science, Research, and Development

---

1. In your testimony on July 7 you answered in the affirmative your own question as to whether science can get large-scale Federal support without running the risk of political interference. Accordingly:

(a) What has happened to private sector support of science education in the face of increased Federal spending? What proportions of graduate science students are self-supported or receive non-Federal fellowships?

(b) Is the Federal fellowship program adversely affecting the programs of private foundations because of more attractive terms?

(c) How can the relatively low science education budget of the National Science Foundation act as a balance wheel against the large sums spent in institutions of higher learning by mission-oriented agencies? Should not the NSF have a say in how all Federal basic research funds are allocated?

1. There is no question that the large-scale Federal support of science has led some private foundations and other donors to turn to other fields of knowledge. On the other hand, it is my impression that private funds for the support of scientific research and science education have held up surprisingly well. The generous level of certain Federal fellowship programs has certainly required private fellowship administrators to reconsider the size of their stipends. This is awkward for them, and resented by those who recall the difficulties they had in financing their own graduate education, but in the main the adequate provision of fellowship assistance seems to me a desirable policy. As for the "balance wheel" function of the National Science Foundation, it would obviously be more effective if the Foundation had a larger budget, but it serves a useful purpose even as a small fraction of the total. I find it difficult to imagine any feasible arrangement that would give the NSF an authoritative voice in determining the allocation of basic research funds granted by other agencies; it can of course exercise some influence by the advice that its staff may give either on a voluntary basis or as a part of the deliberations within the Office of Science and Technology or the Bureau of the Budget.

2. You said the basic procedural safeguard for the independence of scientific institutions from centralized bureaucratic control is provided by the NSF advisory panels, on the principle, as you put it, "that there be no subsidization without representation." In this connection:

(a) There have been allegations that the same advisers, or advisers from the same institutions, frequently serve as consultants

to a number of Government agencies and that this causes the danger of (1) inbreeding of a limited type of favorite research projects, and (2) an elite group of people or institutions in certain geographical areas. What steps can be taken or have been taken to assure that this does not occur?

(b) Are the panels dominated by "big university" membership?

(c) Are small colleges adequately represented?

(d) How about private agencies—including foundations, research institutes, and industry?

(e) Has the use of advisory panels to evaluate research proposals lessened the competence of the Foundation's in-house scientific personnel? Who makes the final decision as to whether a particular project should be supported?

2. To be completely certain that no class of colleges and universities would be specially favored by advisory panels, it would of course be necessary to have such panels made up entirely of people from institutions which did not receive grants. This is obviously not feasible; the system will run only if those who have special knowledge—who are inevitably employed in the types of institutions working in those fields of knowledge—serve on the panels. To prevent inbreeding and favoritism, it is surely desirable to have a reasonably diversified base of membership and to include some panel members, wherever possible, from nonacademic institutions. It would be quite wrong, it seems to me, to say that there is no problem here to worry about. On the other hand, it seems to me that it is a problem that has been handled reasonably well and one that it is impossible to make absolutely pure without rendering it sterile. The most important safeguard, it seems to me, is to have an adequately strong staff with high scientific competence within the Foundation; in the past I am inclined to believe that the great extent of reliance on the outside advisers has probably prevented the development of adequate career staff.

3. In your recent review in the May 7, 1965, issue of "Science," you identified as a fundamental question: How is science, with all its new power to be related to our political purposes and values, and to our economic and constitutional system? As one of the leading students of this question, what is your answer?

3. The fundamental question of the relation of science to our political purposes and values, and to our economic and constitutional system, is of course a question I treated in my most recent book, "The Scientific Estate," a copy of which I recently sent you.

4. You imply in your "Science" review that the early close relationship between scientific and political ideas that characterized the age of Franklin and Jefferson should be revitalized, particularly to strengthen us in our competition with the Marxists who teach that their system is the only approach to politics that is firmly grounded on the scientific method. Do you think it reasonable and desirable for the National Science Foundation to take the lead in such a revitalization? How might this be done?

4. The broad political question of the relation between scientific and political ideas does not seem to me to be the special mission of the National Science Foundation. Obviously it would be desirable for the officers of the Foundation, like all political and administrative leaders, to have an appropriate philosophy in this respect, but I doubt

that they have any particular reason to take the lead in formulating such a philosophy.

5. It is now 10 years since you published "Government and Science." In it you emphasized the importance of applied science both to the forming of our present Government and to its early economic growth. Considering this, what are your thoughts about assigning more responsibility to the Foundation for the application of the results of Government-sponsored research and development?

5. I am rather dubious that the responsibility for the application of the results of Government-sponsored research and development should be assigned to the National Science Foundation, although I would not like to draw a rigid line in this respect to preclude the Foundation from this field.

6. With respect to national science policy, which you discussed at the hearing, do you feel any clarification is needed in the policymaking roles and relationships of NSF, the National Science Board, the Office of Science and Technology, the Federal Council, the President's Science Advisory Committee, the Special Assistant to the President for Science and Technology, and the National Academy of Sciences?

6. I am rather inclined to think that the basic relationship of the NSF to the various parts of the Executive Office of the President, and to the National Academy of Sciences, is sound enough but I dot not think that "policy" is something that can be neatly parceled out among different agencies, and I do not worry very much about the need for complete clarification in the policymaking roles.

7. What problems in the area of science policy do you believe in need of resolution and policy formulation? To what extent do you feel that the present formulation of policy is being adequately reported to the public and to the Congress?

7. The principal area of science policy that seems to me to need policy attention is the relationship of the support of research to the general support of higher education. I am inclined to believe that the work of your subcommittee and others is making a good beginning on this problem. It seems to me to be hampered not by any secrecy but by the normal inertia of the political process.

8. It was brought out at the hearings that a considerable transition has occurred in the character and content of college education in science and engineering in the last quarter century. Is it true that today's academic engineering is not only new and more comprehensive, but actually supersedes or perhaps controverts some of the principles that our engineering colleges taught in the 1920's and 1930's?

8. I do not feel competent to comment on the curriculum problems in engineering colleges.

9. What has been done to attract older professional people back to school in order to update their technical capabilities? Can you report any effective countermeasures to academic obsolescence in science personnel?

9. I hear of various midcareer "retread" programs for scientists and engineers, but I know too little about them to make any effective comments.

10. The best graduate students are frequently unavailable for teaching because the terms of their research fellowship specifically prohibit this activity. Do you believe more research grants should permit some

teaching, to provide flexibility to the graduate and to help in the training of undergraduates?

10. I do indeed believe that research grants should make it possible for research workers, wherever appropriate, to undertake some teaching.

11. As a scholar in government organization, do you believe that the scientific disciplines should have more representation in our legislative bodies? If this is desirable, how might we go about inducing more scientists and engineers to run for public office?

11. I would be happy to see more interest in political activity on the part of any group of citizens, including scientists and engineers, but I do not think that elective office is the only form of participation in public life, and I do not think it is surprising (or particularly undesirable) that scientists and engineers are temperamentally somewhat less inclined to run for office than, for example, lawyers.

12. In your teachings and writings, are you comfortable in relying on the statistical data, particularly with regard to manpower, which NSF accumulates and correlates?

12. The NSF data are certainly the most complete and reliable to be found in any country. The data with which they deal are very slippery, and I have no doubt that a continuous effort toward improvement is warranted. I have not really worked on this problem for some years, and have no particular suggestion for such improvement.

13. Has the NSF provided leadership in the effective coordination of the scientific information activities of the Federal Government with the view to improving the availability and dissemination of scentific information since March 1959?

(a) Has the transfer of fiscal and managerial responsibility for the Science Information Exchange to the Foundation strengthened SIE?

(b) Is the academic community concerned with the field of science and public policy satisfied with statistics and analyses developed by NSF?

(c) What other information and studies are needed? Should these be undertaken by NSF or by others?

13. I have really not followed this story closely enough to have a useful opinion.

14. Section 3(a)(2) of the National Science Foundation Act which authorizes the Foundation to support basic research carries the additional provision that the Foundation is "to appraise the impact of research upon industrial development and upon the general welfare." What has the Foundation done to carry out this provision?

14. I suspect that the section of the act proposing that the Foundation is to appraise the impact of research upon industrial development has not been very effectively carried out.

15. How are Foundation's so-called free funds to universities controlled so as to prevent, for example, their being used possibly to meet unreimbursed overhead costs? Would an improvement in indirect cost allowance policy negate the need for some of these funds?

15. The payment of full indirect costs seems to me to be wholly desirable policy. Obviously this would reduce the temptation to divert funds improperly to purposes not intended by the terms of grants. I have not been personally close to the administrative problem of con-

trolling the use of the so-called free funds and consequently have no comment on this problem to offer.

16. What contributions have the small college and the young unknown investigator to make toward the betterment of science? What specific effort does NSF make to assist them and take advantage of their potential?

16. As a former officer of a private foundation, I can only be sympathetic with the plight of the National Science Foundation in simultaneously trying to make high quality grants, and also give help to the small institution and the unknown investigator. I think this is a dilemma that it is impossible to resolve except by judicious compromise. With more staff the Foundation could doubtless make a more thorough search for talent in the small institutions; how soon they would reach a point of diminishing returns could only be found by experiment.

17. The Foundation in recent years has devoted some funds toward improving science teaching as well as curriculums in undergraduate as well as high school levels. Based on this experience, do you believe that fellowship or institutional support of pregraduate education should be proportionately increased or decreased?

17. I do not feel competent to comment on this question.

18. In your judgment, what proportion of scientists and engineers should have the Ph. D. degree? What is the dropout or failure rate in Ph. D. aspirants?

18. I fear my ignorance extends also to this question.

19. Do you feel that in fulfilling its balance function, the NSF was intended to play a special role in considering geographical dispersion of science support? Has this been done?

19. Certainly some of those who originally proposed the creation of the National Science Foundation hoped that it would take geographical location into account in distributing its funds; other wished it to make its awards strictly on scientific merit, and were terribly afraid of some quota system imposed to meet political demands. In recent years the Foundation seems to have been worried, with good reason, about the need for geographical spread in its grants, and while I have not been on the inside of its operations I assume that that concern has had some influence on its program.

20. Should the Foundation devise and adopt a deliberate policy of distribution of support that is counter to that of other Federal agencies? Has the situation in American science changed sufficiently over 15 years that the Foundation should today avoid support of existing centers of excellence? Would the impact of the Foundation be greater under such a policy?

20. It seems to me that the question of geographical distribution deserves consideration only within the context of the essential purpose of the Foundation. If it is expected to improve the quality of science in the United States, it seems to me that it would be a great mistake to force it to distribute funds in relation to the accidental quality of geography, without regard to the quality of the science in question. I would, for political reasons, be strongly in favor of an effort to build up a limited number of institutions of high quality in regions which now possess none, or few, of such institutions. But it seems to me the first and overriding consideration should be the support of quality, and to avoid the support of existing centers of excellence would destroy the Foundation's program.

RESPONSE BY DR. ALVIN M. WEINBERG, DIRECTOR, OAK RIDGE NATIONAL LABORATORY TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

---

1. In your testimony on July 8 you referred to the 15 percent increase in the budget of the National Science Foundation for 1965 over 1964 and said that you "strongly urge that this trend be maintained or even accelerated so that by 1970, NSF's budget would exceed $1 billion per year."

(a) What about after 1970? Should this growth rate accelerate further, remain at about 15 percent, or level off? What limits the ceiling?

(b) What is your concept or understanding of the base upon which the 15 percent rate is or should be calculated? NSF support of basic research? Fellowship grants, facility development, or what?

1. (*a*) It is very difficult to predict the situation more than 5 years hence. In general, since I visualize NSF becoming primarily[1] (though not exclusively) the supporter of basic physical research in the universities, the growth of NSF should be related to the growth of the universities. Assuming that a fixed fraction of our university students continue to go into science, as the university population grows, the number of science students will also grow. I would therefore hope NSF will continue to grow well beyond 1970, and at a rate determined by the growth of the universities.

Probably NSF should not grow quite as fast as the universities, however. I do not believe that science is the *summum bonum* of our culture, and I therefore do not advocate pushing Federal support, particularly of the physical sciences, above all other activities, Eventually, therefore, NSF's budget should be a certain fraction of the GNP; in this sense, support for basic physical science in the universities will reach some level which is also related to the GNP. I don't believe this should happen, however, until well past 1970.

(*b*) I believe that 15 percent should be divided mostly between support of basic research and facility development; my impression is that, with the passage of the National Defense Education Act, fellowships are not the problem. I believe that the projectizing of support of basic research has been carried far enough, and much more attention should be paid to the geographic distribution of funds for basic research. I favor doing whatever can be done to upgrade scientifically

---

[1] Some who read my testimony have interpreted my remarks as advocating that NSF reduce its support of the basic biological sciences. I do not advocate this: to me biological science will always remain an important field in NSF. I do foresee that its position relative to physical science in NSF may diminish, not because biology decreases but because physical science increases more rapidly.

backward parts of the country—by facility grants, center-of-excellence grants, etc.

2. If Federal funding for R. & D. continues to level off and is not compensated by corresponding growth of support from the private sector, will the future demand for scientists and engineers, other than for teaching, also drop and will this influence future student enrollments in science and engineering?

2. If Federal funds for R. & D. level off, eventually the number of students choosing to study science will drop. However, there is an enormous backlog of unfilled places in science—not so much in research as in teaching. I believe that our country's smaller colleges and high schools need many more, truly competent teachers of science and mathematics. To fill this demand will take many years.

3. In your contribution to the National Academy of Sciences report to this committee, you refer to basic research in the physical sciences being faced with a deep financial crisis, presumably arising because of leveling off of mission-oriented agency budgets. Is there a similar crisis in support for applied research in the physical sciences?

3. I don't believe one can speak of a "crisis" in applied research in the same sense as I spoke of a crisis in basic research in physical sciences. Basic research is motivated primarily by the individual doing the research. Hence the desirable size of the overall basic research effort, as seen from the viewpoint of the basic research community, is determined internally by the separate desires of the individual researcher. To some degree, but only to a degree, our society feels an obligation to support every truly competent basic research scientist. To the extent that there is not enough money to support the growing requirements of the expanding number of basic researchers, a crisis has developed.

Applied research is extrinsically motivated; it is done not primarily because it is of interest to the scientist performing the research (though it may be very interesting to him) but because it is needed to support some project. Thus the fortunes of applied research wax and wane as old projects are completed and new ones are started. The "desirable" overall level of support for applied research is pretty much determined by the needs of the projects rather than the desires of the applied scientists. Individuals doing applied research tend to understand this. Though they are naturally unhappy if a project to which they are attached is canceled, they understand that their claim for support rests upon their contribution to a project, not their intrinsically motivated contribution to general knowledge. One therefore can't speak of a "crisis" in applied science in that there is not enough money to support every good applied scientist. The needs of the applied scientist are largely a reflection of the needs of specific applied projects: both he and his funding agency usually recognize this.

This is not to say that the position of applied science in this country does not need strengthening; in fact, it is suffering from a kind of intellectual crisis. I am very sympathetic with Edward Teller's concern about the relatively poor place of applied science in our universities. But I believe he was referring mostly to the place of applied science in the university's intellectual hierarchy, rather than to its financial support.

*4. The 1970 projection you outlined to the committee envisioned "NIH being concerned primarily, though not exclusively, with the physical sciences; NSF primarily, though not exclusively, with the physical sciences * * * and with those aspects of science that are not properly taken care of by one of the mission-oriented agencies."*

(a) Does the latter include the social or environmental sciences?

(b) Do you believe that NSF funds should be oriented in the future to support applied research on new problems of society such as pollution, urban transportation, and housing? Should such funds support this research in those in-house or contract centers that have high competence but are suffering from obsolete missions?

4. (*a*) I think NSF is a proper home for basic research in the social sciences. I am less clear about the environmental sciences. I have the impression that with the reorganization of the Department of Commerce's environmental science work into a single administrative unit, the Government now has a mission-oriented agency that could take responsibility for basic research in at least certain phases of environmental sciences.

(*b*) I don't think NSF should be used to any great degree to do the research necessary to get on with solutions of our great sociotechnical problems. Rather agencies or departments, once set up to deal with these problems, should have research departments that support the scientific work needed to carry out their missions. Thus urban transportation and housing research ought to be the primary, though not the total, responsibility of the new Department of Urban Affairs; pollution, the responsibility of Interior; and so on.

I agree that contractor establishments of high competence should be deployed to meet the most important problems, whether or not these problems fall precisely within the domain of the establishment's original interest. So to speak, we need governmental laboratories as well as governmental agency laboratories. I would look to the Office of Science and Technology, working with the agencies and with laboratory management, to achieve such redeployment as efficiently as possible.

5. You spoke of the "rivalry between university and Government laboratories." Should more intimate cooperation be developed in graduate education and research between federally supported university science departments and Federal in-house research and technical centers?

5. I strongly favor developing educational ties between Federal laboratories and nearby universities, especially in some of the educationally less developed parts of our country. Here in Oak Ridge we have had considerable success in encouraging cooperation with neighboring universities. I think the Oak Ridge pattern can serve as a model for much of our country.

6. Are you satisfied that the Federal agencies have accepted and are discharging their responsibilities for information activities in fields relevant to their missions? To what extent do you consider that the recommendations of the President's Science Advisory Committee Report of January 1963 on Science, Government, and Information have been implemented? Can you suggest areas where you believe improvement is necessary?

6. I feel that I am no longer close enough to the information problem to offer a fully informed opinion. My general impression is that the Office of Science and Technology has moved aggressively and intelligently in this field, that COSATI is working well, and that the agencies take information far more seriously than before. As for implementing the recommendations of the PSAC report, I am satisfied that as much has happened as one could reasonably expect. In particular, the central role of the specialized information center has been recognized and strengthened.

7. Exactly how do you make use of the Science Information Exchange? What is your impression of its operation and utility since responsibility for it was assumed by NSF?

7. I have not followed the progress of SIE since its takeover by NSF.

8. The point has been brought during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency X, agency Y, or both. Specifically:

(a) What guidelines or criteria has the Oak Ridge Laboratory established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the Laboratory's jurisdiction and, therefore, should, or should not, be supported?

(b) If written criteria have been established, please submit a copy thereof to the committee.

(c) Should NSF support basic research at laboratories such as Oak Ridge?

8. (*a*) and (*b*). In response to your question, I should make clear that ORNL is an Atomic Energy Commission Laboratory. We almost never are called upon, as a laboratory, to support basic research originating outside the Laboratory. Hence questions 8 (*a*) and (*b*) are not applicable.

(*c*) In general, I would not visualize NSF supporting work directly at the mission-oriented laboratories such as ORNL. However, there may arise instances where a mission-oriented laboratory is uniquely qualified to undertake non-mission-oriented basic research that relates closely to some interest of NSF. In this case an exception to the previously stated principle might be countenanced, but I should think that such cases would be rare.

9. Considering the Foundation's interest in manpower development, should the Foundation undertake programs concerned with retraining? What, in your experience, is the best technique to avoid premature obsolescence of scientists and engineers?

9. I am not persuaded that "retraining" is a real problem. I think a more urgent problem is maintaining the sense of mission and purpose of the institutions at which older men work. If new missions are identified that are of great interest and about which people can generate great enthusiasm, then the problem of obsolescence can be largely avoided. So to speak, the problem of obsolescence is not so much that the individual scientist becomes obsolescent as it is that the management becomes obsolescent. I doubt that NSF can contribute much to keeping management on its toes.

Response by Dr. Charles Kimball, President, Midwest Research Institute, to Questions of the Subcommittee on Science, Research, and Development

1. You made the point in your testimony that the National Science Foundation should develop a new program aimed at training certain gifted individuals to be "appliers of science." Would you state in more detail how NSF would go about setting up such a program. What would be its specific objectives? How would individuals be selected? What training would they receive and where? What role could the nonprofit research institute play?

1. A program to train scientists in the social, political, and economic relevance of technology deserves careful attention. If NSF undertakes an effort of this type, it need not and should not be totally separate from existing NSF programs. I suggest incorporating such objectives, specifically in certain existing NSF educational programs.

But the whole task does not need to be undertaken by NSF directly. We need experimentation with different approaches before any policy in this area can be finally set. I have suggested in my testimony of July 8, 1965, that the business schools might logically take on young scientists and engineers, instructing them about the "market value" of technology, and the influence of the marketplace in judging the value of scientific effort.

The independent research institutes can and should help in several ways. First, in MRI's case, we plan to experiment by exposing a few talented candidates for science and engineering Ph. D.'s to the kind of intense conferences we have been operating at Andover, N.H., for the Engineering Foundation over the past 3 years. This would offer a short-term but very intensive exposure to the social, economic, and political consequences of technology for young people, who have spent most of their time in a more protected and isolated academic environment.

A second model which we would like to see expanded, we have for 4 years involved many of our own scientists and engineers in technology utilization programs we operate for NASA. The experience has proved beneficial both to the technical people and to the industrial economists concerned with the program. Everyone's view has been broadened.

We now hope to extend this approach another step—to develop another model which might prove useful to NSF and others concerned with the national issues of applying technology in the public interest; i.e., fellowships at the Institute to bring senior scientists from the world of basic research into a pragmatic environment for a year or two at a time. These could be men from universities, Government laboratories, or from the basic research laboratories of private corporations. The exposure they would receive in an institution like ours to

many different types of research programs, and to the constant pressures for effective solutions within time and cost boundaries, should be an energizing and stimulating experience. We have no doubt that such men will also contribute both depth and new insights to our own staff.

We think these kinds of approaches may offer an answer to several questions: (*a*) exposure of young scientists and engineers to "real world problems;" (*b*) a means of retraining and revitalizing mature technical people whose skills may be going out of date; (*c*) a means of further breaking down cultural barriers between basic and applied research.

Finally, on this point, we hope to undertake this program with the support of private foundations. We see this as an opportunity for the foundations to contribute experimentally to new approaches which NSF and other Federal agencies may later wish to pursue.

As I expressed in my cover letter to Chairman Daddario, questions No. 8 and No. 11, which refer respectively to the retraining of scientific and engineering personnel and the role of the fellowship program of the Federal Government are answered to some degree implicitly in the above response. In addition, I have responded explicitly to questions No. 8 and No. 11 later in this memorandum.

2. Some witnesses have suggested that NSF should not become too involved in the area of applied research because it would require a different type of organization and the Foundation's primary purpose of supporting basic research might be neglected. How would you answer such critics?

2. I question the utility of trying to draw hard-and-fast distinctions between basic and applied science. But in my view, the Foundation's primary task of supporting basic research should be continued and perhaps intensified. It would not necessarily be destructive of this primary purpose for NSF to become involved in some areas of applied research, because the latter type of effort can often suggest and uncover needed areas of basic research. It is generally recognized that gaps in basic knowledge frequently become evident in applied science programs. Our own 20 years' experience at MRI has illustrated this in a large number of instances.

3. How much of the research done by the Midwest Research Institute can be categorized as basic research or, as you put it, "research for opportunity"? Please state it in percentage, if possible.

3. Few scientific research projects are either all basic or all applied in content. Furthermore, few scientists can agree about the precise content of either type of research in a given project. Few of MRI's applied projects do not have some basic content. Currently, between one-quarter and one-third of our total scientific effort, distributed among approximately 125 different projects, is basic in nature.

4. Would NSF support be helpful in pursuing such basic research as you may be doing?

4. Yes, through supplying funds for pertinent equipment, for beginning certain in-house generated projects, and for contracts to study the process of technology transfer and science application.

5. You stated or at least implied that the pursuit of applied research generates many opportunities for profitable work in basic research. Would you elaborate on this point?

5. See answer for question 2.

6. At present several departments and agencies—including NASA, the Department of Commerce, and the Atomic Energy Commission—have technology utilization programs aimed at fostering the commercial application of the results of their research and development. What might the Foundation do to bring about a better understanding of the processes of technology utilization and to lead these agencies toward a common approach?

6. I view with concern, any attempt on the part of NSF to quarterback or arrange for central control for the technology utilization programs now going on in NASA, Commerce, and AEC. Rather, NSF might well sponsor research on ways to improve the effectiveness of the technology utilization process. There is no necessary virtue in having all of the agencies employ a uniform approach.

7. A number of witnesses noted that the Midwest is a leading producer of Ph. D.'s, who subsequently work elsewhere. Do you see a role for the Foundation in obtaining a better understanding of this tendency? What might this role be?

7. NSF could sponsor research on the kinds of patterns which Ph. D.'s having Midwest origins follow; in effect, an origin/destination study of the Midwest's educated scientists and engineers. Some work has been done on this, but mostly on an ad hoc basis—much more is needed, including projections and reasons for moving and returning.

8. Based on your experience as director of a research laboratory, what responsibilities do you think desirable for the Foundation for the retraining of scientific and engineering personnel whose specialties have become obsolete?

8. This refers to an essentially new form of education in the scientific field (with the exception of medicine which has been practicing this for a long while). In many ways, the university curriculum should anticipate this "retreading" need. The recent Weinberg article in Science illustrates this. Postdegree fellowships for men 5 or 10 years out would be one example. NSF could also work with the Office of Education and the Office of Manpower and Training to help these groups set up adult/vocational education programs with emphasis on part-time study, while employed.

9. You suggested the idea of internships to give scientific and technical personnel more insight into economic factors of applied research and development. How would these internships compare with existing Federal fellowships given by the Foundation?

9. My suggestions about internships (see reply under No. 1 above) relate to the need for acquainting new science Ph. D.'s (and other graduates as well) with the facts of nonuniversity research life. This may best be accomplished outside a university. Dr. Teller alludes to this in his recent statement before the Daddario committee.

10. In your view, which is the more important function of the Foundation—the promotion of scientific research or the advancement of science education?

10. The promotion of scientific research is the most important function of NSF. The advancement of scientific education, in the context of my testimony, is a means to that end.

11. Is the science fellowship program of the Federal Government adversely affecting the programs of private foundations because of more attractive terms?

11. I am not to well informed on the Foundation's science fellowship program but it is, I believe, a competitive force in a scarce talent market. It could adversely affect the recruitment efforts of institutions like MRI and industry, by further biasing new graduates in favor or working chiefly on public problems supported by Federal funds.

12. How can the relatively low science education budget of NSF act as a balance wheel against the large sums spent in institutions of higher learning by mission-oriented agencies? Should not NSF have a say in how all Federal basic research funds are allocated?

12. By an overt NSF policy of minimizing overlap, and by acting as a compensating factor in funding fields currently undernourished by mission-oriented agencies, NSF might try to obtain matching fund grants in these undernourished areas from mission-oriented agencies to increase its own effectiveness. I do not believe that NSF should have an overall jurisdiction on how our Nation's basic research funds are allocated. But it can well be a considerable influence in pointing out omissions or dead spots which are significant in the national interest.

13. From the standpoint of objectives, program content and management, which of NSF's programs do you consider to be the best, and which do you consider to be the least useful?

(a) What are NSF's notable weaknesses or deficiencies, and how may they be corrected?

(b) What more could the Foundation do to promote the progress of science?

13. I am not sufficiently informed in adequate scope and depth about all of NSF's efforts, its strengths, its weaknesses, to answer this question meaningfully, without considerable additional study.

14. Another function of the NSF is to collect information about research and development activities. Considering current interest in regional distribution of Federal research and development, what information do you believe the Foundation should collect to adequately show this distribution?

14. The question suggests that the information about geographical distribution of Federal R. & D. funds is not now adequate. We probably need a better definition of R. & D. to offset some misleading figures that may be associated with large testing or operational sites, but beyond showing where the money goes and where the federally funded people are, I have no suggestions. This is an area which deserves additional study.

15. What would be a logical means of measuring the equitable region distribution of Federal science funding—i.e., dollars per State, dollars per capita, Federal technical center or university science center location? In other words, if the Congress should instruct the agencies to purposefully add dispersion criteria to their grants and contracts award procedures, how should the results be measured?

15. There is no one logical means for measuring equitable regional distribution. One suggestion is that States, or institutions in those States, would meet certain thresholds of performance criteria, and might then be eligible for institutional (nonpersonal) grants for generating further capabilities, as is now done by NASA. But Federal dollar inputs should be measured against performance of centers of

competence and not just by proportionate criteria. They should not attempt to "make the competence" from a standing start. NSF could also act in this instance as a balance wheel by overtly helping regions in which the Nation needs or wants to see scientific development take place. In this way, schools and institutions and States which are outside the current "establishment" could well be encouraged and advanced.

16. Could independent research institutes such as MRI take on more of the applied research and contract center operation, freeing the universities for basic research and education?

16. I question the use of the term "freeing" the universities for basic research and education. Most universities have moved into the applied research and contract center business by planned action.

17. In your testimony you mentioned that grant-type support of research was incompatible with contract-type support. Do you mean by this that, were the Foundation to extend its interests to applied research, it would have to turn to grants? If so, what are the respective features of grants and contracts that lead you to this conclusion?

17. Grant-type support is not incompatible with contract-type support. Grant support is incompatible with the needs of many organizations (like most research institutes) who cannot afford to subsidize projects having inadequate grant overhead allowances. It is my understanding that many universities with a large number of grants also have to provide supplemental funding from their own funds.

The grant or contract mechanism itself is not so important in the context of this question, except that people working under contracts are usually expected to provide definite results, where as grants by tradition are viewed largely as financial support mechanisms. The difference here lies in the degree of expectations of results.

18. Do you see any danger of NSF becoming a "creature of the universities"? Are NSF's operations allied too much with the universities? Do you believe that NSF policies are controlled and set too much by those associated with universities?

18. Universities do exert very considerable influence, both directly and indirectly over NSF. Because basic research is regarded as the main province (in the research sense) of the universities, and because NSF is currently concerned almost entirely with basic research, operations are a closed circle. As I said in my text, there are other institutional forms that could make considerable contributions here.

In closing, I think it is appropriate to quote from "The Pursuit of Excellence, etc.," by John Gardner, a remark which well summarizes this issue facing NSF and the Nation: "There is a danger of training scientists so narrowly in their specialties that they are unprepared to shoulder the moral and civic responsibilities which the modern world thrusts upon them. But just as we must insist that every scientist be broadly educated, so we must see to it that every educated person be literate in science. In the short run this may contribute to our survival. In the long run it is essential to our integrity as a society."

Response by Dr. J. J. Rabi, Professor of Physics, Columbia University, to Questions of the Subcommittee on Science, Research, and Development.

1. In your testimony on July 13 you spoke of science as the "intellectual currency" of our time. From your viewpoint as a member of the NATO Science Committee, how has the political stature of the United States grown by virtue of its scientific effort? Can you give examples?

1. I will answer this question by giving some examples:

(*a*) The CERN Laboratory was organized to a large degree on the example of the Brookhaven National Laboratory, and an invitation to Brookhaven National Laboratory is considered a high honor anywhere in the scientific world. At the present time, there are over 100 foreign scientists working in Brookhaven.

(*b*) The large number of foreign scientists in various western countries are getting an important part of their support through U.S. agencies, and this support is concentrated in the most advanced portions of the discipline.

(*c*) In the NATO Science Committee almost all the initiatives come from the United States. Most of the proposals, although by no means all, which we consider sound are accepted. These examples show that the United States has acquired a leadership position in this field which spans the intellectual community and has raised acceptance of the United States on the political side by virtue of its power and continuing accomplishment. We are respected and have a great deal to offer apart from direct support. In this connection I should like to note that at the beginning of the NATO Science Committee the United States contributed 50 percent of the budget, and we are now down to 24.4 percent of the normal NATO contribution, which shows the degree to which the NATO Science Committee and its program has been accepted by the member states and their treasuries.

2. How do you think that U.S. capabilities in science and its support by the Federal Government should be utilized (a) to strengthen international science and (b) to help achieve U.S. foreign policy objectives? What is NASA's proper role in this regard?

2. (*a*) The United States should aim in the future to strengthen international science through its own scientific contribution and example rather than to continue indefinitely to support international science financially. Certain kinds of support which advance important U.S. science programs, of course, should continue.

(*b*) U.S. foreign policy objectives are best achieved, in my opinion, by U.S. excellence and willingness to cooperate. Again, I would like to emphasize that direct financial support should be at a minimum, but cooperation in making knowledge, and in some cases techniques and instruments available would be most effective, as would be visits of foreign nationals properly selected and supported.

I do not understand the NASA program sufficiently well to comment.

3. Assuming that support of an international program has certain political or prestige benefits for the United States, how is this transferred into dollars and cents and how does it relate to the scientific merit of the program?

3. It is my belief that prestige benefits in science ultimately flow into dollars and cents as do prestige benefits in industry, banking, or show business. U.S. scientific equipment becomes more readily salable, U.S. publications find a readier market and ultimately products of U.S. scientific industry.

4. The Foundation itself is not supposed to determine science policy questions, yet the level of support to be given a politically advantageous international program would appear to be a national policy matter. In such a case who does, or who should, determine the overall level of U.S. support?

4. As I suggested in my testimony, there should be a close relation between the Foundation and the other Government departments such as State, Defense, Commerce, and HEW, as well as OST.

5. What is NSF's role regarding overall coordination and funding in relation to the activities of the State Department on the one hand, and the Federal Council and the Office of Science and Technology on the other?

5. I am sure this question is better answered in other testimony.

6. In an international program where a number of Federal agencies participate, should the agency primarily responsible for the program fund for all the agencies involved, thereby presenting the program in a complete package rather than in a piecemeal fashion which may be subject to irregular budget cuts by different congressional committees?

6. I will agree that this is desirable, especially when a greater use could be made of the Federal Council of Science.

7. Following up your discussion with some members of the committee on the relative worldwide emphasis on the physical sciences as compared to the social sciences, would you say that the issue essentially boils down to this: We have learned in this century how to destroy civilization; the question is, have we learned not to? Do you have an answer to this question?

7. We already know how not to destroy civilization. There are plenty of economic, sociological, ethical, and political answers to this question. We have known for ages how to destroy civilization as witness the destruction of the Roman Empire, the Moslem Empire, the Greek Empire of Alexander, and the great empires of the Mongols. Science has taught us in the last few centuries how to create a civilization where there need be no want, no hunger, no superstitious fears, less disease and human suffering, greater communion of nations through better communication, faster travel, more economical transportation. What more do you want?

8. Are any problems raised, such as future support of worthwhile projects, by the termination of international research programs?

8. I recommend that when worthwhile projects are due for termination that the United States do everything possible not to make this termination too abrupt and cataclysmic. We should arrange with the

country in question either a takeover or a gradual reduction and try as far as possible to develop other means of support.

9. What is the nature of the coordination of Federal support for U.S. participation in the International Indian Ocean Expedition which has been assigned to the NSF? How are the NSF's coordinating functions with respect to the Indian Ocean Expedition reconciled with those of the Interagency Committee on Oceanography for coordinating the entire Federal oceanographic effort?

9. I am not sufficiently familiar with this question to reply.

10. What are your views on the establishment of international science centers and cooperative programs to spread the cost of expensive machines and devices? Could basic research at these centers retain its link with the education function in the absence of immediate proximity to a university?

10. I believe that international science in which the United States is a participant should be on the theoretical side, such as scientific economics and sociology which involve the use of large computers, certain parts of biological research which require large animal colonies and large computing facilities for unraveling complex biological structures. The members of these centers should reside for limited times and return to their respective countries and respective institutions and thus further the educational functions within their own countries. The proximity to a university is very useful in maintaining a proper and intellectual level and atmosphere.

11. In view of your public statements about how science can contribute to human welfare, do you believe any additional steps are necessary, or programs should be initiated, by the Foundation to accelerate the application of scientific discoveries?

11. I have no suggestion at the present time with regard to any specific program to be initiated. I will be very much interested if the Foundation together with HEW were to consider the support of educational programs to close the gap between the "two cultures" so as to make science a more central and important part of all education and to broaden the education of the scientists to include history, philosophy, sociology, ethics, and application of scientific advance, as well as the long-term political implications.

12. What should the Foundation be doing toward furthering public understanding and interest in science so that the layman will be better able to live in a scientific age?

12. See 11.

13. In fields of basic research such as high-energy physics, where increasingly large and expensive equipment and laboratories are required, what would you think of a national policy to assign responsibility for financing such installations to the Foundation?

13. This question is a political one. To my mind it resolves to the question, which agency is trusted by the Congress to do the most effective job where national expenditure is concerned? If the Foundation achieves such a respect and trust it would be the natural vehicle for such support.

14. Given the leveling off of budgets for the departments and agencies which have supported most of the research in physical sciences in the past, do you see a dropping off in the need for graduate students trained in the physical sciences?

14. No. The colleges, universities, and secondary schools are very poorly supplied with properly trained teachers in the physical sciences. With increasing enrollments these institutions could use several times the available supply. This answer does not begin to touch on the expanding need of ever-more-sophisticated industry.

15. Should NSF engage in a program of up-dating the science education of U.S. scientists who have been out of the country on assignment for a significant length of time?

15. It would be a great help if the National Science Foundation could supply some fellowship support or grant which would allow the person concerned a period of time to make up for scientific retardation incurred as a result of foreign service.

16. Should Congress authorize increased opportunities for exchange of scientists with other countries?

16. Yes. Because of the high cost of living in the United States it is very often necessary to supplement the income of a visiting foreign scientist. Likewise, an American scientist who goes abroad finds it difficult to get along on salaries prevailing in those countries. In each case, financial aid to proper candidates would make the exchange more effective from the scientific, political, and cultural points of view.

Response by Hon. Francis Keppel, Commissioner of Education, to Questions of the Subcommittee on Science, Research, and Development

---

1. Supplementing your testimony of July 13, what are your agency's long-range plans for the support of science education? How were these plans developed and how are they kept to date?

1. Office of Education plans for the support of science education are integrated into our plans for supporting the educational system overall. Science as such is not emphasized over other subject fields in recent legislation, although there is some legislation, notably Science Youth Clubs, which is directed to the end of science education. Science activities will doubtless receive considerable attention in the operational programs. One of the possible uses of title III of Public Law 89–10, for example, might be the provision of special science courses for the academically talented where such courses were not currently available or the provision of mobile science laboratories for the use of rural students and teachers. Curriculum improvement activities directed to the sciences will continue and are expected to increase rather dramatically along with such activities in other subject fields, all as a result of the recent amendments to the Cooperative Research Act and the additional funds that will become available for the support of activities under that act. Title III of the National Defense Education Act will continue to support the purchase of equipment and nonconsumable materials for science education.

2. Your statement covered rather fully the overall coordination that exists between your office and the National Science Foundation. What coordination is there between your office and the science education programs of the mission-oriented agencies such as NASA?

2. Coordination between OE and other Federal agencies that support research and education in the sciences takes place in much the same way that OE–NSF coordination is achieved. There has been a longstanding informal group of Federal agency heads concerned with research and education programs, who have met from time to time to discuss common problems and policy directions. Dr. Seaborg, Mr. Webb, representatives of the National Institutes of Health, and other mission-oriented supporters of research and education, as well as the Director of NSF are members of this group. This informal coordination at the top will be further strengthened when the Federal Interagency Committee on Education is fully activated. (We are now proceeding to recruit staff to perform secretariat functions for this Committee.)

Below the agency-head level, the same committees that I described as assisting OE and NSF to coordinate their interrelated functions operate in a similar fashion with other Federal agencies as well. Thus the ad hoc committee to assist coordination in the various agency's

programs with respect to graduate education facilities includes representatives from NASA, NIH, AEC, as well as representatives from NSF. The same is true for a longstanding informal committee of representatives of agencies with graduate fellowship and trainee programs in the sciences: representatives of the programs whose interests are mission oriented exchange information views with agencies whose interests are science and education, per se, or endeavor to make programs as complementary and reinforcing as possible.

But the continuing day-to-day contact and cooperation between operating people of the various agencies with interrelated programs is still the most important way to achieve the greatest degree of coordination and reinforcement of programs between OE and the agencies with mission-oriented education concerns. Let me give some examples of how OE science education specialists, and people in the NASA education programs divisions have worked together to carry out projects of great significance to schools, and which neither could have done so well without the help, know-how, and funds from the other.

Early in 1961, NASA asked OE to help them in identifying ways to maximize the impact of NASA funds available for improving science education at elementary and secondary levels, as well as increasing the impact of NASA spacemobile services to schools. Consultation and cooperation at working levels have been continuous ever since. The two agencies worked out many joint projects, several of which have been especially significant, and have extended to involve other agencies. Let me cite two or three examples:

(1) Maine project: Office of Education specialists, in cooperation with the Maine State Department of Education, assisted a Maine school district in assessing its science instruction and in planning a self-improvement program to meet the needs of inadequate teacher training in science. The OE specialists then cooperated with NASA educational specialists in extending the single district experiment, and planned a statewide pilot instructional effort, patterned after the method of inservice education developed by the aforementioned school district. Together, NASA and OE assisted the State of Maine to plan for the evaluation of the project, and area evaluations have been carried out. Through the continued joint efforts of the OE specialists, Maine Department of Education personnel, and NASA representatives, a plan for dissemination of information about this inservice teacher evaluation program is underway. NASA will soon publish a report called "The Maine Story," which has been written by an OE specialist. Plans for distribution include all State departments of education and teacher training institutions.

(2) In June 1964, NASA, with the cooperation of OE, sponsored a national conference for State science supervisors, NASA educational personnel, and one of the AAAS science education subcommittees. Purposes of the conference include further exploration of the role of science education, particularly as it relates to the Nation's space effort, development of plans for implementation of science instruction, and provision of opportunities for the science educators representing various geographic and governing units to work together on specific problems. Proceedings were published and serve as excellent reference material.

(3) NASA is one of numerous Government agencies which has been involved in OE-sponsored research on educational research conference exhibits, and is a member of an informal interagency committee to improve the educational quality of exhibits in science, social science, arts, and other fields of knowledge. The purpose of these research conferences, and for the committee is to provide exchange of information and to coordinate research endeavors in the exhibit field, which is becoming an increasingly important aspect of education in the sciences, social sciences, and the arts.

3. What State, private, and foundation support for curriculum improvement is available today?

3. Very little support is currently available from State sources for the support of curriculum improvement. Private sources, including several foundations, have devoted some of their funds to this activity. The foundations have played their traditionally significant role as "pump primers." The Carnegie Corp., for example, began the funding of Prof. Max Beberman's mathematical project, the support of which his since been taken over by the National Science Foundation. Carnegie has continued its interest in the curriculum area with support to Harvard's Project Physics in its initial stages, a project which is currently being supported by the Office of Education and is soon to be jointly funded by the Office and NSF. The Kettering Foundation and the Sloan Foundation have also become involved to an increasing extent in this kind of activity. Probably the major foundation support for curriculum improvement has come from the Ford Foundation which has assisted Educational Services, Inc., in its social sciences program and awarded a series of grants under their small school improvement project, many of which have gone for curriculum improvement.

*4. You testified that "coordination of Federal activities in support of curriculum improvement is necessary, to assure the continued existence of alternative choices for local policy planners * * *."*

(a) Do you consider this to be the responsibility of the Office of Education? If not, whose responsibility is it?

4. (a) We take coordination of curriculum improvement activities to be a responsibility of any agency engaged in them, and since we have a strong commitment in this area, both in terms of resolve and in terms of funds, we feel a need and recognize a responsibility to perform this kind of function. That does not mean, however, that the Office of Education is the only agency which ought actively to seek to coordinate its activities. We would argue, in fact, that any Federal agency engaged in curriculum improvement ought to coordinate those activities with other agencies so engaged.

(b) Is it statutory or voluntary?

(b) Coordination of this sort is not statutory.

(c) In the field of science, does the coordinating responsibility belong to NSF?

(c) The coordinating responsibility could be met in the sciences by the National Science Foundation, but we are prepared to assist if and when such assistance seems necessary or desirable.

(d) Are private programs in curriculum improvement a significant factor?

(d) Private programs in curriculum improvement have been a significant factor in the past and are likely to be in the future. The foun-

dations in particular are in a position to play a role here of great importance. While it is true that NSF and OE have supported and presumably will continue to support large-scale projects in curriculum development, often the beginning efforts are more appropriately stimulated by funds from private sources.

5. Is sufficient support being given to the social sciences by NSF and other Federal agencies?

5. It has become increasingly clear to all Americans—to scientists and educators, to those concerned with the problems of government at Federal, State, and local levels, to businessmen, and to parents and citizens—that the support of social science research must be increased if we are to find answers to and provide solutions for our accumulating and pressing social problems.

The calls to increase and apply our social science knowledge come from every quarter: from those attempting to bring about full employment and flexible labor force, from those trying to solve the problems of our bulging cities and withering rural areas, from those trying to improve the organization of Government services and to increase productivity and creativity of private enterprise; from those responsible for protecting the mental and physical health of the Nation, and last but not least from those trying to improve our educational system. For educational research and development leans heavily on knowledge in the various social sciences, in economics, sociology, psychology, and combined and interdisciplinary fields as these disciplines are related to solutions to problems of educational content, methods, materials, organization, and administration.

Since education R. & D. is an area of research for which OE is primarily responsible, I think it is relevant to point out that it is in fact one of the areas of applied social science and hence dependent on the state of knowledge in many of the basic social science disciplines.

The facts about Federal funds for social science research seem to be these:

(1) In 1964, within total Federal R. & D.—$14.9 billion. All agencies spent about $79.4 million on basic research in the social sciences—psychology, sociology, economics, geography, political science, etc.

(2) When educational research is added to expenditures for basic social science research, the amount totals $111.2 million.

(3) When federally supported expenditures for education carried on by educational institutions in the social sciences are added to research, the grand total, including fellowships, traineeships, training of Federal employees, institutional grants for basic social sciences and various social science applied and combined fields such as foreign area studies comes to $192.7 million in 1964. (See table entitled "Federal Funds for Education in the Social Sciences".)

Federal funds for education in the social sciences, fiscal years 1961, 1962, 1963, and 1964 [1]

[Amounts in thousands]

Field of study and program	1961	1962	1963	1964

Federal funds for education in the social sciences, fiscal years 1961, 1962, 1963, and 1964 [1]—Continued

[Amounts in thousands]

Field of study and program	1961	1962	1963	1964
Applied social sciences, NEC—Continued				
Federal employee training	0	$2	$1	$2
Employee training, Justice	0	0	0	1
Employee training, GSA	0	2	1	1
Combined fields, total	$3, 356	4, 644	9, 913	17, 651
Research	3, 356	4, 644	9, 913	17, 651
Cooperative educational research	3, 356	4, 644	6, 985	11, 500
Manpower development and training	0		2, 928	61, 51

[1] Includes programs identified by field of study in survey of "Federal Funds for Education and Related Activities." Some programs, for example, Department of Defense R. & D. funds in universities, were not reported by specific fields of study and data are not available and therefore not included in this tabulation.

[2] Grants in social science fields are included in other categories.

(4) This is a pretty small slice of total Federal expenditures of Federal funds for research, education, and training which totaled $6 billion in 1964.

While Federal expenditures in research, education, and training in the social sciences increased from $160.2 to $192.7 million, I think there is substantial agreement that this increased Federal support for research, education, and training in the social sciences must be accelerated. Increases achieved so far create a firm base for future expansion of social science research and education. Through research grants, graduate fellowships and traineeships, we have substantially increased the number of competent researchers and teachers. We have begun the job of examining the state of teaching social science in our schools and colleges.

I do not think we can afford to be complacent about our progress however. We will be pushed by events—by crises if you will—to find answers to situations for which undone social science research should have supplied us with answers. I think the present efforts to effect desegregation of our schools and cities and to find cures for chronic poverty are examples of this.

It is encouraging, however, to look at the rate of increase in expenditures for social science research and education by Federal agencies. Dr. Haworth has provided figures showing that NSF support for basic research in the social sciences is increasing faster than research support in any other field. It has risen from a total of $4 million (including psychology) in 1960, to $16.3 million in 1964, a fourfold increase. During the same period 1960–64, OE expenditures for educational R. & D. have increased from $10.8 million to $21.5 million.

6. Federal support of quality manpower development is concentrated in postgraduate education. Nevertheless, high-quality graduate students come only via undergraduate production.

(a) At what grade level in our modern educational structure does a student chart his course toward science, engineering, social studies or the arts?

6. (*a*) The college years, since this is where conscious and deliberate career choices in the areas of science, engineering, social studies, or the arts are most frequently made. To say this, however, ignores the vital role of elementary and secondary education to create the predispositions or capabilities on the basis of which the in-college choices can be made. The answer also ignores the frequent changes in career choice that do occur after college. The point at which the choice is made, then, may be worthy of some attention, but other levels of the educational system may be of equal significance in setting the conditions for that choice.

(*b*) *Should the National Science Foundation exert influence by the investment of support at this level?*

(*b*) The answer to this question, of course, rests on the reply to (*a*) above. Clearly attention should be paid to all levels of the educational system, not just the one where the choice happens to be finally made. The Foundation is in effect doing this by its curriculum programs in elementary and secondary education and at the undergraduate level, and through its support of fellowship and facilities programs.

(*c*) *Do you believe that fellowship or institutional support of pregraduate education should be proportionately increased or decreased?*

(*c*) Fellowship and institutional support of undergraduate education should be substantially increased. Such support, however, ought not to be categorical, particularly in relation to fellowships. By offering noncategorical fellowships, doors for future choices can continue to be kept open for individual students. In addition, title III of the new Higher Education bill will materially aid developing institutions through the provision of teaching fellowships and authorization for the support of cooperative agreements to strengthen undergraduate programs.

7. *With the great emphasis being given to "new starts" in education, are our educational programs overlooking the retraining of experienced scientists and engineers whose specialties have become obsolete?*

7. The direct answer to the question is a flat "Yes." Given the scientific, organizational, economic, and occupational dynamics of modern life, the need for occupational updating and retraining is now a universal need. It is a need, however, which is not now being met systematically by any major program at the State or Federal level. Scientists and engineers are by no means special cases in this respect. They are served just as well as other occupational categories, which is very little at best. An exception is the recent Sloan Foundation grant to MIT to develop materials and programs designed for engineering retraining. The medical profession has also turned its attention to this problem delivering an extensive report with recommendations some 3 years ago. By and large, however, we are still pretty close to ground zero in this important area.

Part of the problem stems from the absence of reliable data on a variety of measures associated with this kind of activity. Estimates and projections of the future size of the retraining clientele and costs of such services cannot be made until we develop data on present enrollments and sources of funding of such educational services, including the share of costs borne by employers in relation to total overhead and operating costs. We also require data on expenditures by

individuals at various occupational and income levels for their own retraining and updating, including out-of-pocket costs and foregone earnings. We need more information on present public funding at the State level or in institutions of higher education in support of retraining activities, including unemployment insurance, and more complete information on what Foundations are doing in this area.

I might add that the administration Higher Educeation bill contained some thrust in the direction of retraining and continuing education in the original title I, but as the bill came through committee and passed the House, the purpose had shifted somewhat to a more directed concern over the problems brought about by increasing urbanization and the contributions of institutions of higher education to the solution of those problems. Some of the original thrust has been restored to the bill in the Senate, after being removed from the House version. Title I as it now stands in the Senate will enable us to make a start toward meeting this growing problem.

8. From the standpoint of maintaining excellent teachers, how effective is the retraining of teachers who have been in the field for a number of years, compared with continuing the training of students who have just finished with their graduate or postgraduate degrees?

8. Comparison between the retraining of teachers who have been in the field for a number of years to continuing the training of students who have just finished their graduate degrees tends to be misleading. First, we cannot afford an either-or choice. We need more excellent teachers than either one of the two techniques alone can provide us. Second, individual teachers will always require both methods to insure the continuation of their excellence. The production of excellent teachers require high quality initial educational and training experiences, but if they are to continue performing at high levels, teachers will need frequent refresher courses to keep up with new developments in educational research and curriculum development at the elementary, secondary, and higher education levels. It must also be said, however, that teachers who are trained without the recognition that they will need future retraining are in effect being done a disservice. The effective utilization of retraining techniques rests on preconditioning the teacher to an understanding of their value and importance. The absence, in many cases, of this kind of preconditioning may be counted as one of the continuing weaknesses of teacher-training programs as they now exist.

9. Our support of universities and colleges appears to be heavily weighted on the side of research, as distinguished from the education of students or the training of teachers.

(a) Is this deliberate national policy?

(b) Which do you consider more important—the promotion of science research or the advancement of science education?

(c) Do you see any danger of turning our colleges—that is, their science and engineering departments—into great research laboratories?

9. The distinction between Federal support to higher education institutions for basic research and for education of students is to a considerable extent an artificial one. It is undesirable, if not impossible, to carry on good graduate education in any field today away from a research environment. Unless the faculty are involved in

research and the students themselves carry on research, the education they receive is likely to be marginal.

I do think there is a problem if research and teaching become organizationally separate functions in our higher education institutions, or if research remains as concentrated as it is in a relatively few major universities. To the degree that researchers do only research in separately organized research units on the campus, and teachers do only teaching, or some institutions do little or no research, we are creating barriers between the production of new knowledge and its dissemination. Such barriers automatically create the probability of obsolescence among faculty members who are not involved in research.

Our statistics on research and teaching manpower in universities and colleges are expressed in full-time equivalents of individuals doing each function. This tends to cloak the degree to which the divorce between teaching and research is happening. To the degree that it has happened or is happening (and I think there is evidence that it has happened in the weaker colleges—the ones that have received little in the way of research grants, have inadequate research facilities or resources for updating faculty) we must take steps to remedy the situation.

Both OE and NSF are working on complementary lines of remedial and preventive action. NSF has established programs of institutional science development grants, teaching-oriented research grants, research participation arrangements for college faculty in major university research centers. OE is planning to expand its institutes programs to include college faculty in all fields, and to involve college faculty—who are, after all, the teachers of most of our potential elementary and secondary teachers—in the continuing process of updating through the activities of the new educational laboratories soon to be created under the amended Cooperative Research Act. The mission-oriented agencies research programs are also contributing to preventative and remedial action by opening laboratories to university and college faculty as well as graduate and undergraduate students, through the establishment of research fellowships, traineeships, and assistantships.

Given present awareness of the dangers of letting a gap grow between research and teaching in colleges and universities, I think the possibility of turning our higher education institutions into great research laboratories to the detriment of teaching will be avoided. The remedial and preventive measures indicated above will have to be increased, however, if we are to succeed.

10. What rate of growth in support for facilities and for students is needed to meet the needs of graduate student enrollments? What does a 15-percent increase per year, which has been suggested for Federal support of academic research, imply for scientific manpower which has been increasing at about 6 percent per year?

10. The primary determinant of the need for more higher education academic facilities lies in the challenge of increasing enrollments. Current projections indicate that graduate enrollment is expected to rise from approximately 577,000 in 1965 to 834,000 in 1970 and to 1,066,000 in 1975. These are conservative estimates which do not take into account the stimulative effects of new programs such as the student loan program or the significant expansion of the graduate fellowship program. It has been estimated that merely to meet the graduate

program needs for new and enlarged facilities covered by the graduate enrollment increase would require a total investment of approximately \$129.0 million in 1966, \$196.0 million in 1967, and \$290.0 million in 1968. To this should be added \$61.0 million for 1966, \$66.8 million for 1967 and \$68.7 million for 1968 for the cost of future replacement, rehabilitation, and modernization of current facilities. In addition, the backlog of obsolete and substandard facilities was estimated to be approximately 90 million square feet of graduate and undergraduate instructional facilities in 1961. The cost of the graduate portion of the backlog is estimated at \$233 million. These figures give some measure of the support for facilities needed to meet graduate student enrollments.

The availability of facilities is obviously only part of the problem of meeting the needs of increased graduate student enrollments. Another important factor is the financial ability of students to attend colleges and universities. During fiscal 1963, which is the latest year for which we have comprehensive data, Federal support to college and university students amounted to \$225 million for 232,000 students in 802 universities. These included all but three of the Nation's top 100 institutions of higher learning as rated on the basis of Federal research expenditures. Federal graduate student support for this period amounted to \$153 million for 102,000 students. Since graduate enrollment was approximately 475,000 in 1963, Federal support was extended to slightly more than one-fifth of these students. (This is a rough approximation since the number of students receiving support includes some duplication where students received assistance from more than one Federal source.) If this same ratio is maintained, this would mean an additional 10,000 graduate students to be supported in 1966 and an additional 14,400 graduate students to be supported in 1967 based on graduate student enrollment estimates. Using the title IV, NDEA, graduate fellowship average of \$5,000 per year per student as a basis, this would mean an added \$50 million for 1966 and \$72 million for 1967. This is based upon the present doctoral level fellowship program. A new Teaching Professions Act of 1965 has been proposed to meet the master's degree needs of elementary and secondary teachers. One estimate has placed the cost of this graduate fellowship program at approximately \$40 million for 4,500 fellowships in 1966, and approximately \$115 million for 4,500 continuing fellowships plus an additional 10,000 fellowships in 1967. These figures given both a rough index of support needed to meet present graduate student enrollment projections with present programs as well as some indication of the additional support required for the new program.

A 15-percent increase per year in Federal support for academic research would appear to be a reasonable rate of increase—at least for the immediate future. You are already aware of the efforts being made to determine more accurately the optimum rate of change of Federal support in this area. From the testimony of Dr. Haworth, Dr. Hornig, and others, you know that the 15-percent figure takes into account increased costs of doing research as well as increasing numbers of graduate students. Because of this, it is not clear to us that this rate of increase of academic research support will lead to additional strains on our scientific manpower supply that will not exist

in any case if we continue to provide an adequate rate of increase in science graduate enrollments.

In 1962 about 350,000 scientists were employed in the United States; by 1975 science manpower requirements may be near 650,000. In addition to the 300,000 increase in the number of scientists required for growth, another 100,000 will be needed to replace experienced scientists who die, retire, or leave the profession for some other reason. This expected growth will reflect the needs placed on technical manpower by the Nation's aerospace, health-related research, defense, technical assistance, and other programs. Broadly speaking, mathematics and physics will be among the fastest growing fields; the largest science fields—chemistry and the biological sciences—also will expand rapidly. Interdisciplinary areas, such as those found in oceanography, biophysics, and metallurgy, can be expected to expand greatly. Current levels of the training of chemists, physicists, and mathematicians are not expected to provide enough supply to meet anticipated future demands during the 1965–75 period. Relative to most other scientific and technological fields, the supply of biological scientists would be more likely to meet future requirements. An estimated 50,000 social scientists were working in 1962. Although they were in a variety of occupational fields, the majority of social scientists were employed by colleges and universities. The demand for social scientists will continue high throughout the 1965–75 period as college enrollments continue to increase. Growing numbers will also be needed by Government, industry, private foundations, and research organizations. Manpower requirements in the social sciences are expected to grow to nearly 90,000 in 1975. Approximately 55,000 new persons will have to enter the field in order to account for growth as well as replacement needs.

11. Do you think Federal support to higher education should extend to students interested in the management sciences, industrial engineering, and business administration as these relate to application of the results of scientific research? If so, is this responsibility suited for the National Science Foundation or for the Office of Education?

11. Federal support of the "management sciences" is very necessary, but should not be restricted to, or concentrated in any one agency of the Federal Government.

Historically, the management sciences grew out of the effort to advance the processes of decisionmaking and administration of research. Now, however, the management sciences, combining analytical approaches of both the natural and social sciences, together with techniques of quantitative measurement and applications of the computer to finding solutions to complex management problems through operations research, systems analysis, model building, et cetera, are becoming essential instruments for the efficiency of every large-scale undertaking, including Federal agencies, State, local governments, business concerns, and educational institutions and systems. Every Federal agency whose mission involves large-scale operations or the conduct or support of research must, therefore, be concerned with the research on, and the development of, management techniques that assure better management of its business. Thus, NSF, as well as other Federal agencies concerned with management of research in support

of their missions, have in varying extent conducted or supported research in the management sciences.

This is as it should be. One can argue that the level of support given to this field has been inadequate, but one cannot, I think, make the case for its concentration in a single agency.

Educators are becoming increasingly aware that the level of support to research in the management sciences as applied to education has been too low. Education has only begun to nibble at developing and using the management sciences to find solutions to the complex problems of running the huge establishments that our universities, and school systems have become. Research and application of the management sciences to education will be one of the areas where education R. & D. funds will be increasingly applied by the Office of Education, both through external research grants and contracts, and internal applications to the management of the Office itself.

The current development, for example, of a comprehensive, computerized educational data system by the Office of Education is a major step in application of the management sciences to education.

12. Will you discuss the activity to date and the plans for the Federal Interagency Committee on Education, particularly with respect to coordination of graduate student and institutional support programs of the various agencies, stipend standardization, allocation between fields of science, collection, and interpretation of statistics?

12. The Federal Interagency Committee on Education has held its initial meeting, at which the secretariat responsibility for the Committee support was lodged with the Office of Education. Under the new organization plan of the OE, this duty will be assumed by the Assistant Commissioner for Planning and Evaluation, who is now being recruited. The Office of Education hopes to have this position filled and the Committee backstopped in the matter of a few weeks. The purview of the Committee will include all the matters included in the question.

13. Have the cooperative fellowships and graduate traineeship programs succeeded in balancing the tendency for fellows to seek training only at a few top-rated schools? Or has this attempt at dispersal of support to more schools been diluted by other concentrating effects of Federal funding in institutions of higher learning—for example, by the concentration of research grants, research facilities, and the location of research centers? Has the number of centers of academic excellence grown?

13. I understand that NSF has submitted data to the subcommittee concerning the cooperative fellowship and graduate traineeship programs. These data show that the fellowships and traineeships in these programs have been distributed much more widely among the Nation's graduate schools than the regular NSF graduate fellowships. The cooperative fellowship program is being discontinued after fiscal year 1965, but the traineeship program is being expanded and will be supporting twice as many students as the regular fellowship program in fiscal year 1966. The tendency for fellows under the regular program to concentrate at top-rated institutions will thus be strongly counterbalanced by the policy of wide distribution of assistance under the traineeships program. An additional strong counterbalance is the National Defense Education Act, Title IV: Graduate Fellowship Pro-

gram, administered by the Office of Education, which has, since its establishment in 1959, given highest priority to assisting developing institutions and increasing the numbers of centers of academic excellence. One indication of the decreasing concentration of graduate education at the level of the doctorate is the fact that the percentage of the Nation's doctorates awarded by the Keniston-Berelson group of 12 top-rated institutions[1] has declined from 31.4 percent in 1959–60 to 29.8 percent in 1963–64. Another is that the number of institutions awarding 100 or more doctorates increased from 29 in 1959–60 to 43 in 1963–64.

14. With science education and basic research so intimately linked throughout the NSF program, what does this portend for the small college which is unable to support a vigorous R. & D. effort but still wishes to graduate high quality bachelors of science?

14. Our figures on the organization of research reveal a growing distance between undergraduate teaching and involvement in research. The linkage between science education and basic research throughout the NSF program means that small colleges unable to support a vigorous R. & D. effort have not been ordinarily able to look to the NSF program as a means of strengthening the competence of their scientific faculty.

The problem exists not merely because these colleges are excluded from the benefits of the program in some degree. It is also a concomitant of the direction of NSF funds to other, stronger academic centers which has tended to draw scientific competence away from the small college.

NSF is fully cognizant of this problem and its importance. It is adapting its programs insofar as it can within its legislative mandate to mitigate the problem. The problem will only be overcome by a concerted effort under which the programs of the NSF and OE are mutually adapted in the light of definitions of criteria and a classification of institutions agreed upon by both agencies.

There are several existing or developing programs in both agencies which are designed to attack this problem. NSF is expanding its program of research for small colleges, in effect attacking the problem head on. The Office of Education is approaching it directly by expanding institute programs for retraining college teachers and by providing assistance for cooperative graduate centers of excellence under title II of the Higher Education Facilities Act to provide for the development of programs beyond the capacity of individual institutions.

In addition, grants and loans under title I of the Higher Education Facilities Act are available for equipment and buildings for scientific instruction and research. Grants are approved under this title in accordance with criteria approved by State commissions. It has, however, been the policy of the Office of Education to encourage the commissions to develop standards which preserve the competitive position of the small colleges.

Title III of the proposed Higher Education Act of 1965 will also undoubtedly play a major role in strengthening both research and instruction in small colleges. The aid possible under this title not being limited categorically—for example, to facilities alone—can be directed

[1] Cf. Bernard Berelson, "Graduate Education in the United States," McGraw-Hill, 1960, pp. 124–128.

toward any of the particular weaknesses of a small college. Inter-institutional relationships will also be fundamental to this program as is also the case of the graduate centers of excellence under title II of the Higher Education Facilities Act. Although small colleges may not have the resources to undertake highly specialized research, they can through association, retraining, and exchange of faculty members come to have sufficient participation in or exposure to, research and new learning in order to maintain academic standards of excellence.

Finally, the national program of educational laboratories shortly to be announced by the Office of Education ought eventually to have some impact in this area. Curriculum improvement activities at the elementary and secondary level have now taken on the nature of a continuing activity, but at the college level we still have some distance to go before we can legitimately say we are meeting our full responsibility. The cooperative relationships that will be created in the conduct of the laboratory program between small and large institutions and between institutions of higher education and the schools as well as the direct improvement of undergraduate curriculum as part of the functions of these laboratories should also be of considerable significance in insuring the production of high quality bachelors of science.

15. Are the Foundation institutional grants consistent in policy and content with those of HEW, NASA, Department of Defense, and other Federal agencies? What is the general amount of private sector support in these same programs?

15. In our estimation this question is better answered by the Foundation than by USOE.

16. Exactly how do you make use of the Science Information Exchange?

16. The Office of Education makes use of Science Information Exchange in at least two ways. Under the cooperative research program and the research and demonstration program directed to the problems of handicapped children and youth by the Bureau of Research, principal investigators have been required to complete SIE abstract forms for inclusion in the SIE system of ongoing research. SIE has returned multiple copies of the forms to OE, the cooperative research program, and the research program for handicapped children and youth. The files of these forms have been consulted in answer to requests regarding particular projects. The abstracts have been forwarded to the requester for his information.

The second use that has been made of SIE is in connection with program planning activities. Since SIE keeps a record of all inquiries made, by asking them who has made requests for certain kinds of information it is possible to locate individuals and institutions who are working on problems of interest to the Office of Education. This knowledge has proved particularly valuable for the development and extension of new and existing programs.

17. Considering the pros and cons of diversity of support versus centralization in one agency, what would be the advantages and disadvantages of combining in one Federal department or agency all of the various educational and training programs relating to scientists and engineers?

17. The disadvantages of combining in one Federal department or agency all of the various educational and training programs relating to scientists and engineers would far outweigh the advantages of control, organizational visibility, and administrative simplicity. Many of the agencies in need of scientific and engineering manpower have specific missions to perform and require personnel trained to work in the areas of their responsibility. By administering their own programs of manpower, education, and training related to their specific needs these agencies can contribute directly to the conduct of the programs they are charged with by insuring a sufficient supply of adequately and appropriately trained manpower. The value of the separate agencies administering their own programs directed to the training of scientific and engineering personnel does not, however, detract from the need for a strong measure of coordination, a function which is now being met by the Office of Science and Technology.

18. In your opinion, what are the prospects of meeting the goals of the Gilliland report? If these goals seem unattainable by present efforts, what more might be done, and by whom?

18. The goals of the Gilliland report are the following:

(1) Increase the number of doctor's degrees awarded each year in engineering, mathematics, and physical sciences to reach 7,500 in 1970.

(2) Increase the number of students who complete a full year of graduate training in engineering, mathematics, and the physical sciences to reach 30,000 during 1970.

(3) Encourage the strengthening of existing centers of excellence in engineering, mathematics, and physical sciences and develop new centers of educational excellence.

(4) Promote wider geographic distribution of centers of educational excellence.

According to most recent trend projections, the number of doctor's degrees awarded in engineering, mathematics, and the physical sciences in 1970 will be 7,890 and the number of students completing master's degrees will be 38,550. Gilliland committee goals (1) and (2) should thus be exceeded. Evidence such as that set forth in answer to question 13 indicates that goals (3) and (4) are also being gradually achieved. In addition to the National Defense Education Act title IV fellowship program and the NSF traineeship program, progress toward goals (3) and (4) is being made under the Higher Education Facilities Act title II, graduate facilities program and the NSF science development program to assist developing centers of academic excellence.

19. The point has been brought during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency X, agency Y, or both. Specifically:

(a) What guidelines or criteria have been established by the Office of Education to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the agency's jurisdiction and, therefore, should, or should not, be supported by the Office of Education?

(b) If written criteria have been established, please submit a copy thereof to the committee.

19. The Office of Education research programs are directed to research, surveys, demonstrations, and dissemination in education. Frequently this means research in social science disciplines related to the field of education such as sociology, psychology, anthropology, and other social sciences. Because of the particular mission of the Office of Education research programs the problem of which agency should fund a given project comes up relatively infrequently. It occurs most often, however, in the area of curriculum development in some of the developmental grants to support conferences discussing educational research needs. Since all curriculum improvement activities are within the scope of the Office of Education research programs, decisions regarding proposals which might be funded also by NSF are made on an individual basis. Generally speaking, however, a proposal has been directed to NSF only when the Foundation had already had some funding experience with the program for which funds are being applied or where joint support is specifically requested. No written criteria have been established for determining whether or not a particular project was within our purview or that of NSF.

20. Further supplementing your testimony, what has happened to private sector support of science education in the face of increased Federal spending? In this connection, what proportions of graduate science students are self-supported or receive non-Federal fellowships? Is the Federal fellowship program adversely affecting the programs of private foundations because of more attractive terms?

20. The most recently completed study of stipends received by students for graduate study covering 37 fields including science and nonscience disciplines produced the following results. In science fields 70 percent of the graduate students had stipends of one kind or another. In nonscience fields 47 percent of the students had stipends. The students were asked to name the source of their support and reported for science that 38 percent had support from Federal sources and 62 percent had support from non-Federal sources. (These figures are open to considerable question, however. A later check revealed that in many cases students reported their institutions as the source of their stipends when in reality the stipend they were awarded was part of a Federal program of one kind or another.) In nonscience fields the study revealed that 10 percent of the students reported stipends from Federal sources while 90 percent reported that their grants came from non-Federal sources. (These figures are subject to the same uncertainty.)

The study also revealed, however, that only a relatively small group of the science students, 4 percent, received support from foundations. The corresponding figure was only 9 percent for the nonscience disciplines. The proportionately small size of foundation support in this area suggests that the adverse effects of programs for Federal fellowships on Foundation programs of a similar sort are limited.

The National Center for Educational Statistics in the Office of Education is currently working on a study of 20,000 graduate students and within 6 months or a year we should have considerably more (and more accurate) information on these matters.

Response by Dr. Harvey Brooks, Dean, Division of Engineering and Applied Physics, Harvard University, to Questions of the Subcommittee on Science, Research, and Development

1. As a member of the National Science Board, do you believe that a change in the wording of the NSF Act to permit increased operational or applied research by the Foundation would be advantageous?

1. On balance I believe it would be desirable to broaden the NSF Act to permit applied research, although I would recommend that this authority be used sparingly and with discrimination, chiefly in conjunction with its contribution to graduate education in applied science. I do not believe that NSF should attempt to support work in applied science which is clearly and exclusively related to the mission of some other Federal agency. For example, it would be quite undesirable and inefficient for NSF to support research aimed specifically at the improvement of the postal service because there would be little chance of such research results being incorporated into the work of the Post Office. On the other hand, it might be appropriate for NSF to support fundamental work on systems analysis in which an analysis or model of the postal system was used, as it were, as a "test bed" for new concepts and principles of systems design involving social and economic factors as well as technological factors. I do not favor the Foundation being authorized to conduct in-house operations.

2. What are your views as to the appropriate balance in the conduct of basic research as between universities, the Federal Government, and industry?

2. Industry should be encouraged to support basic research which it considers to contribute to its own objectives. In the case of industry doing business with the Government, I support the idea of an industry being permitted to support basic research as a part of its indirect cost allowance on Federal procurement. I am generally opposed to specific support of industrial basic research by small project grants or contracts, except in unusual cases where industry has a unique capability not available elsewhere. Similarly I believe Federal laboratories, whether in-house or contract research centers, should be encouraged to participate in basic research as part of their overall mission. I do not believe it is meaningful to talk about the relative amounts of basic research among different performers. This will vary from field to field depending on its relevance to particular industries or Federal laboratory missions. I believe the present situation in which universities (apart from contract centers) perform about 40 percent of basic research is a fairly healthy one, but because of the special stress which is now being placed on higher education nationally I believe that the proportion of basic research performed by universities should be permitted to grow relative to industrial and Government research, at least until the present graduate student "bulge" flattens out.

3. In view of your comments on the need to avoid insullation of basic science from applied goals, what do you believe is the distribution and attitude among scientists concerning support from the Foundation as compared to other agencies? What mechanisms would you suggest as enhancing the transfer of information from basic to applied areas?

3. My comments on the need to avoid insulation between basic research and applied goals pertained specifically to basic research performed in nonacademic institutions with applied goals; e.g., health or defense technology. However, the same comments apply to some extent to research supported in academic institutions by mission-oriented agencies.

Most university scientists prefer their support to come with as few strings attached as possible. On the other hand, as long as they are free to pursue their research, most scientists like to feel that their work is used by others. Scientists are conscious of the fact that they enjoy the greatest freedom in choice of field of work if they deal with NSF. On the other hand, they also recognize that they can obtain support on a larger scale if their work falls within the field of interest of a mission-oriented agency. A scientist interested in biochemistry, for example, usually has as much freedom and better support from NIH than from NSF. On the other hand, if the progress of his research began to lead him into, say, the physical chemistry of inorganic materials, he would probably ask for additional support from NSF.

The most important mechanism of translation for supported academic research is the corps of scientific program officers in Washington. This overworked and underappreciated group has the responsibility of providing an "impedance match" between the basic research they support and the needs of their agency looking well into the future. This requires being aware of much more than the current problems and "requirements." It demands the imagination and perceptiveness necessary to see where new science could be exploited to fulfill agency missions. This involves not only a thorough understanding of science, but also the ability to reinterpret and redefine both the problems and missions of the agency in the light of scientific possibilities, leading to the creation of what may amount to new missions for the agency. An important function of program officers is to foresee problems of the agency down the road for which basic knowledge may be important; e.g., that basic understanding of radiation damage to solids will be needed because of future requirements for the use of electronic equipment in space. I believe that one of the reasons support of basic science by the mission-oriented agencies has faltered in recent years is that there has been insufficient appreciation, both within the Government and within the academic community of the vital and creative role of the scientific program officer. As programs grow the number of such officers must grow also, so that they have the time and the freedom from harassment by short-range problems to think creatively about their job.

Within institutional laboratories the important concern should be that where the laboratory has an applied mission even the basic scientists understand and believe in the mission and are prepared to devote some of their effort to thinking about the applied part of the program and pointing out where basic science could contribute to it.

4. Your testimony on July 14 emphasized academic research, as distinguished from the education of students or the training of teachers. This raises a question as to which role is more important for Foundation support—the promotion of scientific research or the advancement of science education? As an educator, what is your answer?

4. The essential point is that academic research and the training of students, especially graduate students, are not separate or conflicting functions. For example, the NSF fellowship and traineeship programs would be virtually worthless if there were no research support available for the students to work on their Ph. D. dissertations. Even at the lower level of undergraduate or high school teacher instruction, what is taught depends on advancing research. Science, even at the undergraduate level, is not a fixed body of knowledge which can be poured into the student once and for all. Thus my answer to the question is that both are important and over the long run should be kept in some kind of balance. From year to year, however, some problems may require greater attention than others. At the present time I believe the two most urgent problems are the development of and realization of research capabilities in universities through science development and the basic research grant program, and the intensification of work on the improvement of science curriculums at the college level.

5. You stated that "It is a commonplace that the universities are the appropriate and logical locations for much of the Nation's basic research." Do you see any danger in this policy of turning our colleges into great research laboratories, possibly at the expense of teaching?

5. The danger, of course, exists. During World War II some colleges were turned into great research laboratories in support of the war effort. The best people were recruited from smaller institutions all over the country and concentrated in a few large universities and research centers where they had no contact with teaching. For the most part teaching was done by mass production and was training rather than education. The output of Ph. D.'s dropped precipitously. All of these developments were justified by the war emergency. They did no permanent injury to science because the balance between teaching and research was rapidly restored when the emergency ended. Nothing resembling this wartime trend is discernible in the present situation, nor do I see any likelihood of it, short of a tremendous injection of funds for some kind of crash program. In most cases the aims of basic research and education are congruent, not in opposition.

Some problems are beginning to appear owing to the changing technology of certain research fields, most notably high-energy physics. Here it is often difficult to adjust the needs of education to the requirements for the advancement of science. Facilities for research at the frontier are so complex and expensive that they must be concentrated at a few centers, and this requires that faculty and graduate students be away from the campus for much of their time if they are to participate in such research. But people are aware of this problem and are making ingenious organizational inventions to overcome it.

Throughout history the greatest researchers have had an irresistible urge to impart their knowledge to the next generation of scholars.

This urge is so strong that many of the most creative people have preferred to stay in universities despite the fact that the conditions for research are sometimes less attractive than in the best industrial and Government laboratories.

Universities are centers of learning. This implies the responsibility both to develop new knowledge and to pass it on to the next generation. In a great university these functions must be inseparable. Research itself is simply an extension of the learning process to a more advanced level, in which the human teacher is replaced by nature herself. Recent work in curriculum development has, in fact, tended to make the teaching process, even at the elementary level, more like the research process by guiding the student to learn from nature by himself.

6. *Would you object to the National Science Foundation expanding its activities by supporting research abroad either by foreign scientists or support of U.S. scientists on foreign assignment? How about retraining U.S. scientists who had been working abroad and were out-of-date in their speciality?*

6. I am not particularly enthusiastic about the NSF supporting foreign scientists or expatriate American scientists on an expanding scale when there are many good scientists in U.S. universities who cannot obtain support for lack of funds. The NSF may appropriately support foreign scientists when their work clearly enhances the value of domestic programs.

This will occur most frequently in the field sciences where simultaneous observations in different parts of the world are essential or where a special location is needed to obtain certain data. In such cases it may be more efficient to support foreign observers than build or send American scientists and equipment to the location. I believe the NSF should support foreign scientists and international programs mainly when such support enhances our own scientific output.

As regards retraining repatriated American scientists I see no reason for a special program, except possibly in cases where scientists have made large professional sacrifices to serve the Nation abroad as by participating in foreign aid assignments, teaching in underdeveloped nations, or taking up urgent Government posts abroad. Otherwise, I think repatriated American scientists ought to compete on the basis of quality with domestic scientists who may require retraining, but should not be given any additional consideration. They should be eligible along with others for such programs as postdoctoral fellowships, traineeships, or science faculty fellowships just like any other American scientist in the appropriate category.

7. *The best graduate students frequently are unavailable for teaching because the terms of their research fellowship specifically prohibit it. Do you believe research grants to a full degree should permit or encourage some teaching, both as a means of providing flexibility to the graduate and helping in the training of undergraduates?*

7. In most fellowship programs the terms have been modified to permit a limited amount of extra teaching compensated by the university over and above the fellowship stipend. In my experience this has had a dramatic effect on the quality of graduate teaching assistants. I feel the practice should be made universal for federally supported fellowships. Not all my colleagues agree, but my own opinion is that

teaching by research assistants should be permissible up to some percentage of their time, but should be compensated separately so as to give the student a greater sense of responsibility. It is my observation that a limited amount of teaching by graduate students, say not more than one-quarter time, does not interfere with their research progress. There are few people that can spend all their waking hours on research with profit, and most students will take on a limited amount of teaching as additional work without seriously cutting into their research.

8. At what grade level in our modern educational structure does a student chart his course toward science, engineering, social studies, or the arts?

(a) Should the National Science Foundation exert influence by the investment of support at this level?

(b) Do you believe that fellowship or institutional support of pregraduate education should be proportionately increased or decreased?

8. We really know very little about this subject. There is some limited evidence to indicate that students in science and engineering chart their course much earlier than students in other fields; this is especially true for the physical sciences. There is considerable attrition along the way, especially in engineering. The best scientists usually turn out to have chosen science as a career as early as junior high school.

(*a*) This would probably be desirable if we knew how. Apparently the high school curriculum development programs, while greatly improving the preparation of college students in science, has not greatly affected the fraction of students choosing science as a career. Physics has actually fallen off relatively, as has engineering. On the other hand, it may well be that improved high school curriculums will lead to less dropout from science along the way.

Present thinking is that the formative influences may be exerted even earlier, and it is for this reason that many of the leaders in curriculum development are beginning to turn their attention to elementary science and mathematics as well as other nonscience disciplines. I think the NSF should support curriculum development in elementary science to the extent that outstanding scientists and teachers can be interested in participating. However, I believe the limiting factor here is the quality of the people who can be involved in the effort, and broadcast support will have little influence and may even have negative effects. The purpose of such effort is not only to make sure that all children who have a potential aptitude for science have the opportunity to choose science for further study, but also to insure that an increasing fraction of the population will become literate in regard to the spirit and method of scientific inquiry.

(*b*) I do not believe fellowship support for undergraduate education in science as such is especially desirable. Undergraduates are too uncertain of their abilities and interests and should not be coerced into science by financial considerations. I am not, however, opposed to undergraduate fellowship support provided it is not restricted as to field of study. I believe that institutional support should be increased proportionately, but primarily on a selective basis; e.g., by equipment grants for undergraduate laboratories, or to support innovations in undergraduate teaching, or to support faculty development in non-

research-oriented institutions. For the most part such support should be given competitively on the basis of quality.

9. Since the creation of NSF in 1950, there have been created within the executive branch, the Office of the Special Assistant to the President for Science and Technology, the President's Science Advisory Committee, the Federal Council for Science and Technology (of which the Director of NSF is a member), and the Office of Science and Technology (in which is now vested the previous national policymaking authority of the Foundation). Question: What science policy function does the National Science Board now serve which is not adequately provided for by existing organizational arrangements within the Executive Office of the President?

9. Policy is not a finite or homogeneous entity which can be cleanly separated from operations. Policy is made at every higher level of Government. Every policy decision has to be interpreted in terms of its concrete application to the problems and issues which arise at each level from the President down and such application itself constitutes policy. The National Science Board has to interpret Office of Science and Technology recommendations in terms of their implications for the Foundation's programs. In the budgetary competition the science Board usually takes responsibility for decisions as between programs inside the Foundation, but the Science Board cannot properly advise on its own programs which may compete budgetwise with programs in other agencies. To an increasing degree the Science Board has been taking the initiative in making policy recommendations with respect to programs or administrative matters which have Government-wide implications, but obviously such recommendations have to be correlated with those of other agencies. In my experience the creation of OST has greatly enhanced the role of the Science Board, because the OST supplied the mechanism by which Board recommendations can be translated into Government-wide policy. Without OST the Science Board had nobody to talk to in the Executive Office, since there was no mechanism for harmonizing and correlating its recommendations with the rest of the Government's science activities.

It is even literally inaccurate to state that the previous policymaking authority of the NSF is now vested in OST. This authority is by explicit statement of Reorganization Act No. 2 shared between NSF and OST, with the Foundation still retaining primary responsibility for policy in basic science.

10. Since you have served simultaneously on the National Science Board, the President's Science Advisory Committee, the Committee on Science and Public Policy of the National Academy of Sciences, and as consultant to the Office of Science and Technology, have you seen examples of confusion because of overlap in policymaking roles between these bodies?

10. I have seen no evidence of confusion to date in the various policymaking roles. I admit that such confusion might arise if there were not close liaison between the various groups. So far, for example, the President of the National Academy has been a member of PSAC and the Chairman of COSPUP, a consultant-at-large to PSAC. One or two members of COSPUP have also been PSAC members, and members of OST staff and of the science planning activity of NSF have participated frequently in COSPUP deliberations. For example, an

OST staff member attended many meetings of the COSPUP survey panels for physics and chemistry and ground-based astronomy as an observer. Confusion is avoided because COSPUP is not a Government organization, and it is understood by all that its views and reports do not represent official policy of the U.S. Government. Its function is to present representative views from the scientific community for the consideration of the Government. In no sense does it make policy. Its studies have been confined primarily to the area of "policy for science" whereas PSAC has devoted most of its attention to the area of "science in policy." OST and PSAC reports are part of the Government policy process; they are true "policy staff papers"; i.e., they propose actual policy positions for the Government. In general the role of PSAC has been primarily one of throwing new ideas and new considerations into the policy arena, while OST has concerned itself more with the ongoing process of hammering out policy, including but not confined to the innovations and critiques provided by PSAC and its panels.

11. When the NSF was created in 1950 with a budget limited to $15 million, the National Science Board could, presumably, exercise close supervision over the workings of the Foundation. Since that time, the budget of the Foundation has increased to about $480 million and the Board has delegated much of its authority to the Director, keeping for itself the authority for major policy decisions. In effect, then, the Board serves as a sort of board of governors, and is the only such nonregulatory agency with this form of dual (Board and Director) authority and responsibility. The question then arises, Is it in the best interest of the country and of science in general to still maintain this dual authority, or would it perhaps be better to have the Director solely responsible for the management and operation of the Foundation, and have the Board serve in an advisory capacity to the Director (a National Science Advisory Board)?

11. On balance my view is that the Science Board should be advisory to the Director. This was my position in 1961 when I was developing a PSAC position for Reorganization Plan No. 2, and my subsequent experience as a Board member has reinforced my conviction. My only reservation about making the change now is that it might be misinterpreted by the scientific community. The one concrete advantage I can see in the present arrangement is that it protects the Director when and if he is subjected to improper political pressures regarding the distribution of funds or other decisions. He can then state that he is legally constrained by the approval or disapproval of his Board. But organizationally I think the Director should have sole responsibility for the management and operation of the Foundation. One argument often used in favor of the present arrangement is that the Board would insulate the university community from an arbitrary or incompetent director. On the contrary I think that if the Board were advisory it would be in a position to speak out much more freely if it became dissatisfied with the management of the Foundation. If the Board were made advisory, however, I believe the membership should still be subject to Presidential appointment and Senate confirmation, and that it should be chosen in approximately the present manner, with nominations from professional societies and other representative groups.

12. Dr. Don Price stated that the real input of the scientific community to the programs of the NSF came from the various Advisory Panels and not from the National Science Board or the Divisional Committees which were recently abolished. Would you care to comment?

12. If I understand correctly what he meant, I agree with Dr. Price's statement. I take it he intended to indicate the scientific views of the scientific community, e.g., their views as to what fields were ripe for support, who were the leading investigators, what criteria should be used in selecting projects, what the priorities were among projects, etc. On the other hand, the Board does concern itself with broader issues such as the creation of new national centers, the overall allocation of the budget, policies regarding payment of faculty salaries, the development of new programs, etc. Both inputs are essential.

13. Supplementing your testimony, do you feel that the Foundation has allocated sufficient resources to study national policy, considering that the amount spent each year is considerably less than that being spent; for example, on Project Mohole?

13. I am not convinced that substantially more money allocated to the study of national policy would produce a significantly better product than we are now getting. The amount of money allocated to any given topic is not necessarily proportional only to its importance. It also depends on how much is required to obtain a given quality of output. The only choices with respect to Mohole are to do it or not to do it. One might decide that it is not worth the price, but one could not decide to buy half a Mohole. Similarly, I don't think twice as much money would buy twice as useful science policy. It might only buy confusion. I think science policy is important, and we should be prepared to devote greater resources to its study when and if promising opportunities become apparent—including people with the competence to do the work.

14. Would not your "proposal pressure" system for priority lead to encouragement of fads and fashions? Also, how should the Foundation deal with "proposal pressure" in concrete terms in view of the hazards of inflation of proposals? In fact, what is the significance in the present sharp variation as between different fields of science in percent of funds awarded as compared to proposals received?

14. I perhaps overstated the case for "proposal pressure" because I felt it had been critcized excessively. It is not clear to me how proposal pressure would lead to fads. Fads in science are usually stimulated by the publication of fundamental new discoveries which open new possibilities for scientific advance over a broad front. They are not all bad. Indeed they are sort of the free enterprise American way of achieving concentration of effort in important fields without fiat from above. The philosophy of proposal pressure is based on the concept that the collective judgment of many working scientists as to what is important and significant is likely to be better than the judgment of any single committee or program administrator. Fads are always a hazard in any human community, but by and large I believe collective fads among intelligent, dedicated, and informed people are less likely to be harmful to science than administrative fads, and that's why I put my faith in the collective wisdom of the scientific

community. As I indicated in my testimony the task of the competent program administrator is to discern this collective wisdom with the proper discounts for personalities or other factors which a good man in contact with his field and his advisory groups usually can make. Inflated proposals are very hard to get by advisory committees, especially if there is not enough money to support all proposals. Proposal pressure is a measure of priorities only if the number of proposals exceeds the number that can be supported. It is a measure of relative priority not of the total amount of money that should be allocated to a field. Regarding the last question, there is a wide variation among program officers in the degree to which they discourage proposals orally when they know there are insufficient funds. I believe this accounts for most of the variation between different fields. In small communities such as astronomy the program officer usually knows the field well enough to be able to discourage verbally applications which are not likely to be supportable. Thus there is a high percentage of support of proposals actually submitted formally. I would never suggest that proposal pressure should be used as a rigid formula for determination of priorities. However, I do say it is a useful and significant input to the decision process when tempered by good judgment and sound knowledge of the actual content of the science.

15. Have problems in collection and analysis of statistics by the Foundation come to your attention as a member of the National Science Board; as for example, through the criticism in the recent reports of the National Academy of Sciences? More specifically:

(a) Do you think the Foundation is using adequate up-to-date instrumentation for its statistical procedures and for data collection?

(b) Can you suggest other ways in which NSF's compilation and analysis of statistics could be improved as to completeness, timeliness, and authenticity?

(c) Has the Board acted on this general problem?

15. I would not have interpreted the statements regarding statistics in the NAS reports as criticisms of the Foundation. The remarks in my own paper were directed not so much at the statistics themselves as at overly simplified interpretations of them that have often been made. Statistics never satisfy everybody because everybody wants them for a different purpose. There is still no general agreement either within the Board or within OST as to what statistics are most relevant and useful for policymaking. The collector of statistics always finds himself in the position of trying to outguess the policymaker, to decide what statistics he will want 2 years from now. This is not easy, and one cannot blame the NSF for occasionally guessing wrong when the policymaker himself (including myself) isn't quite sure what he wants.

(*a*) On the whole, yes. This is in the course of modernization. The biggest problems lie in the sources of the original data rather than in the massaging of the data at NSF. Most of it must be collected by questionnaire, and there is already a surfeit of government and other questionnaires. Furthermore, the hidden costs of collecting data by questionnaire are probably very high, and

one has to make a careful evaluation of the usefulness of each piece of data in relation to its cost.

(*b*) This is under discussion in OST and the National Science Board. Improving statistics is a matter of constant feedback between user and producer. I would hesitate to make any suggestions publicly without careful checking with the professional collectors of statistics. My ideas might be totally impractical and would only prove an embarrassment later. In particular, the costs involved in new statistical programs may be too high. On the whole I feel I have little to add to the few suggestions I made in my written testimony.

(*c*) Only to the extent of encouraging the Director to upgrade the planning activity in NSF, and in constituting a long-range planning committee of the Board which concerns itself with the information needed for planning as well as planning itself.

16. What long-term role do you see for the smaller colleges and universities in science and education? Has on-campus research become so important that those institutions which cannot afford it must sooner or later withdraw from education in the life and physical sciences?

16. This is an exceedingly difficult problem which, in my opinion, has not been fully faced up to by the scientific community. By and large the NSF staff has led the way here rather than waiting for initiative from the scientists. The principal problem of the smaller campuses is how to attract competent physical scientists without providing them with on-campus research opportunities. I do believe the weaker of these institutions will be gradually forced to withdraw from serious education in the sciences. However, I believe there are many measures that could be taken which will at least slow this process and preserve the position of the stronger institutions among this group. Some examples are:

(*a*) Curriculum development at the college level and wide dissemination of teaching materials which can be used in colleges. The NSF is already supporting work in this area and could support more if funds were available.

(*b*) Specific support for college faculty members to return to university campuses or national centers for research experience, also for travel to professional meetings, etc.

(*c*) More collaboration between universities and colleges on a regional basis, with Federal support to take care of the incremental costs.

The NSF has already initiated a number of programs along these lines.

17. Is sufficient support being given to the social sciences by NSF and other Federal agencies?

17. Federal support for the social sciences has been growing more rapidly than for any other scientific area, but the growth is taking place on a very small initial base. On the other hand, Federal support for the social sciences in universities actually exceeds that for chemistry, for example. The difficulty is that this support is quite selective, with principal emphasis on fields relevant to mental health. At present we lack clear evidence that there are good ideas for research in the social sciences which are not being explored for lack of support. I think there is a need for a more systematic and expansive study of

possible opportunities for research in the social sciences than has yet been made. This may be an example of where "proposal pressure" is not a sufficient index of what could be done if funds were available and a few leading scientists were encouraged to think in terms of much more ambitious projects. A new study of the social sciences is being planned by COSPUP.

18. Have the cooperative fellowships and graduate traineeship programs succeeded in balancing the tendency for fellows to seek training only at a few top-rated schools? Or has this attempt at dispersal of support to more schools been diluted by other concentrating effects of Federal funding in institutions of higher learning—for example, by the concentration of research grants, research facilities and the location of research centers? Has the number of centers of academic excellence grown?

18. It is hard to define "success" in this area. If an equal distribution of fellows regardless of quality of institution is considered as an objective in itself, then the program has not succeeded. On the other hand, the traineeships particularly have resulted in a wider distribution of awards. By any statistical measure we can devise, the concentration of research funds and of Ph. D. production has decreased in the last 15 years. In fiscal year 1950, 11 universities spent 50 percent of Federal research and development funds, and 65 accounted for 90 percent, whereas by 1962 the first 10 institutions accounted for only 38 percent of the funds, 20 accounted for 50 percent of the funds, and 100 for 90 percent of the funds. In these terms the concentration has decreased by almost a factor of two. In 1930–39, 10 institutions produced 49 percent of the science and engineering Ph. D.'s but by 1960 they were producing only 35 percent. The proportion of Ph. D.'s produced by the first 15 institutions dropped from 65 percent to 46 percent. Although no statistics are available the impression among observers is that spread of quality has been faster in those fields which have been federally funded. There are probably more very good chemistry departments than history departments, for example. If one is to complain about "concentration" I think it cannot be in terms of saying that Federal funds have increased concentration but rather of saying that they have not produced as rapid a dispersal of quality as might have been desirable for other than scientific reasons. The number of centers of academic excellence has certainly grown. The most dramatic increases in Federal funding in percentage terms have occurred in institutions which were of negligible scholarly importance 10 or 15 years ago.

19. It was brought out at the hearings that a considerable transition has occurred in the character and content of college education in science and engineering in the last quarter century. Is it true that today's academic engineering supersedes or perhaps controverts some of the principles that our engineering colleges taught in the 1920's and 1930's? What has been done to attract older professional people back to school in order to update their technical capabilities?

19. The content of engineering has completely changed since the 1920's and 1930's. For example, at that time electrical engineering was largely power engineering and heavy electrical machinery and transmission equipment. Many electrical engineering students never heard of Maxwell's equations. Today whole new areas of physics

and mathematics have appeared as part of the engineering curriculum: the propagation of electromagnetic waves, solid state physics, atomic physics, information theory, the computer sciences, modern automatic control theory, and most recently optics connected with lasers. Similarly in aeronautical engineering the whole science and engineering of supersonic flight and of hypersonic flow is a relatively recent development important in engineering education. All of these represent aspects of engineering that never existed before, and many are based on principles which were not known. On the other hand, it would not be correct to say that today's academic engineering controverts principles taught in the 1920's and 1930's. It is just that the principles of the 1920's and 1930's are not enough for today's engineering.

There has been considerable activity in the area of attracting older professional people back to school. A number of universities and technical schools such as MIT have extensive programs in this area.

Response by Dr. James A. Shannon, Director, National Institutes of Health, to Questions of the Subcommittee on Science, Research, and Development

1. In your testimony on July 14 you identified NIH as "not primarily a science agency," but rather a health agency, utilizing science as a means rather than considering it as an end. Accordingly:

(a) What do you believe to be the relative roles of NIH and the National Science Foundation in the support of the biological sciences?

(b) In the same context, how about the social sciences?

1. In their support for particular disciplines in the biological and social sciences, NIH and NSF follow quite differing principles; however, the principles followed are those characterizing each agency's engagement with science generally. Distinctive missions contribute to these differences. Distinctive missions have generated diverse sources of Federal support—the overriding pattern for science that has evolved since World War II. (In this pattern, the main flow of support for science has been through nonscientific agencies, which have been permitted—and indeed encouraged—to use science as a means to accomplish defense, space, health, and other social goals.)

Because NIH has a health and not a science mission, NIH supports science disciplines only to the extent these are considered to have "health relevance" (i.e., may contribute to understanding or solution of health problems). The judgment on "health relevance" of particular disciplines must in some part be intuitive or a priori. But for any discipline, there is a more objective measure in the aggregate number and significance of projects that have been proposed and individually judged to have health relevance. Where this health relevance is seen clearly (as it is most certainly in the biomedical sciences) NIH will provide support within program guidelines both for current research projects judged to be meritorious, and to enlarge the resource base for continued growth in the future. In accordance with this principle of health relevance, NIH provides support for basic and applied research projects in all fields of science as well as for related fellowships, training grants, and research facilities and resources.

Thus, NIH provides support in depth for the biological sciences but with preponderant emphasis upon disciplines such as biochemistry, pharmacology, biophysics, genetics, microbiology and physiology among others which undergird the study of human organisms, disease phenomena, and health problems. In planning its programs NSF takes into account the primary interests of mission-oriented agencies and serves to provide basic research support in fields and disciplines within the biological sciences which are not emphasized in the mission agency programs such as botany and zoology, assuring that research in these fields does not languish. NSF also provides support for

highly specialized fields such as marine biology in a few major national centers. NSF activity in biology is also concerned with improvement of secondary school teaching through summer institutes for high school teachers, curriculum improvement, and meeting other educational needs at the secondary, undergraduate, and graduate level. NIH activity is confined to support of research and research training at the graduate and postgraduate level.

The NSF–NIH relationship in respect to the social sciences is of a comparable nature.

2. You said NSF "occupies the keystone position in the arch of our Nation's science support and science advancement programs." What guidelines influencing NIH programs are provided by NSF in this key position?

2. The comment that NSF occupies a "keystone" or "central" position among Federal agencies supporting science was not intended to suggest NSF issuance of guideline for mission-oriented programs. Rather, it referred to the unique statutory roles of NSF in support of sicence and science education as ends in themselves. Thus NSF programs in science constitute the essential element in Federal science support activity that together with the several missions creates a cohesive whole. It referred also to the fact that any significant change in NSF support role (for example, assigning NSF exclusive responsibility for basic research support; or, alternatively, for supporting applied research activities on a much greater scale) must have an important impact on the ability of other science support agencies to fulfill respective missions.

Although the functions initially assigned NSF by statute and Executive order strongly stressed science policy responsibilities and implied some degree of responsibility for general guidance of Federal science programs, no guidelines relevant to NIH were issued; and in the Reorganization Plan of 1962, this responsibility for guidance was passed to the new Office of Science and Technology.

As an instance of specific provision of leadership in solution of common science problems, one may cite the semiannual conferences on fellowship programs which are held under the auspices of NSF. At these conferences, managers of the various agency fellowship programs try to work out common approaches to stipends, support levels, and other policy and procedural matters.

3. What is the relationship between NIH and the Office of Science Technology at the White House?

3. The relationship between National Institutes of Health and the Office of Science and Technology at the White House is, in most respects, essentially comparable to that of all other agencies.

In some respects, however, the National Institutes of Health's experience is unique. First, the quality of science sponsored by the National Institutes of Health and the planning and management of its programs was the subject of an intensive inquiry. In February 1965 the results of this inquiry were presented to the President by the Wooldridge Committee in its report, "Biomedical Science and Administration: A Study of the National Institutes of Health."

The Committee, in its acknowledgements, stated that:

> Few committee reports have had a stronger reason for extensive acknowledgments than has this one. In all, nearly 1,000 competent and busy people have been involved to the extent of hours, if not days or weeks, in the study here

reported. The largest number—about two-thirds of the total—must be saluted only anonymously. They were the scientists and administrators in the many universities, medical schools, hospitals, corporations, and research institutes into which the path of investigation led. Despite the disruption of effort, induced inefficiency, and sheer nuisance value of the invasion by visiting experts, the institutions involved displayed a degree of patience, cooperation, and helpfulness that contributed immeasurably to the success of the mission.

Anonymous acknowledgement will not do for the scientists and administrators upon whose information gathering the study was based. These exceedingly busy men took, on the average, several weeks out of their heavy schedules to visit laboratories and clinics, talk to scientists and administrators, and write reports.

* * * Finally, something must be said about the subject of the investigation—the National Institutes of Health. It would have been understandable if the underpaid and overworked scientists and administrators of this organization had opposed the investigatory activities of the Committee and its inevitable interference with the demanding business of NIH. Perhaps some of them did. Nevertheless, the overall quality of the response was high. Despite the very considerable amount of extra effort that they had to put in to answer the inquiries of the Committee, its panels and staff, the NIH representatives, from Dr. Shannon on down, were admirably helpful and cooperative. The general impression this gave was that of an organization with nothing to hide. This was consistent with the conclusions reached by the Committee as a result of its study.

Secondly, the National Institutes of Health as a bureau within the Public Health Service of the Department of Health, Education, and Welfare does not participate directly in the activities of the Federal Council of Science and Technology. It is, of course, represented by the Department's Federal Council of Science and Technology member, the Assistant Secretary for Health and Medical Affairs. The National Institutes of Health's staff, when called upon, participate fully in the subcommittees and panels of the Federal Council of Science and Technology, and other ad hoc groups advisory to the Office of Science and Technology. The Director of the National Institutes of Health serves in a technical capacity, as a consultant at large to the President's Science Advisory Committee and its Chairman, the Director of the Office of Science and Technology. The Director of Laboratories and Clinics of the National Institutes of Health serves as a member of the Standing Committee of the Federal Council of Science and Technology.

4. Do you consider the Policy and Planning Council for NIH proposed in the Wooldridge report similar in responsibility and function to the National Science Board? What changes would establishment of such a council imply for NIH?

4. The answer to this question is "No." Although the Wooldridge Committee did not spell out precisely what duties and responsibilities it considered appropriate for the Policy and Planning Council it recommended for NIH, it is quite clear the Council would differ significantly from the National Science Board. The National Science Board is the policymaking body for the National Science Foundation. In addition to establishing general policies for the Foundation, the Board must either approve, or delegate authority to the Director or Executive Committee to approve fellowships and grants or contracts for basic scientific research activities. By contrast, the only responsibility of the Policy and Planning Council for NIH would be to provide the Director, NIH, with the best possible advice on the total NIH program—particularly long-range planning aspects and optimum allocation of resources to achieve policy objectives and program goals. There is no implication in the Wool-

dridge report that the advice of the Policy and Planning Council would be binding on the Director, NIH, as would be those of the National Science Board on the Director of NSF. The two bodies would be similar, however, in their focus on major policy and program issues, and their freedom from concern for day-to-day operating details of respective agencies. Moreover, a similar mix of national science and public affairs leaders would constitute the membership of both bodies. These bodies, therefore, would tend to provide similar reassurance that in the development of these key national programs, the views of the scientific community and of the public are heard and weighed.

5. The primary mission of NIH, as you put it, is "the support of medical research." Supplementing your testimony:

(a) How do you distinguish between basic and applied research?

(b) What proportion of total research funds do you feel should be devoted to each, in the context of NIH's mission?

(c) Do you have any measure of the rate at which funds for basic research in the universities should increase?

(d) What are NIH's long-range plans in this regard?

5. (*a*) Great material advances in man's health and well-being depend upon the "breakthrough" discoveries which emanate from fundamental research. Pragmatically, basic research is the pursuit of knowledge which does not yet exist; applied research is the application of existing knowledge to solve problems, to innovate or improve processes and products, and in the field of medicine, for example, to advance etiology, diagnosis, therapy, and rehabilitation.

However, as Dr. C. V. Kidd observed:

> Descriptions and definitions of basic research have at least two kinds of potential uses. The first is to convey—generally to nonscientists—a sense of the nature of basic research, a feeling for its importance, and an appreciation of the motives and working conditions of scientists. One ultimate purpose served by such a description is to expand the scientific capacity of the country by creating understanding of, sympathy for, and support for, the full array of conditions that seem to be conducive to the production of basic findings.
>
> To serve this function satisfactorily, basic research can be described in general, impressionistic terms, and logical precision is not required.
>
> A second use of definitions of basic research is to provide rational, and adequately precise, criteria for decisions required in classifying research as basic for the purpose of compiling statistics * * * basic research can be and has been adequately for the first use, but basic research has not yet been defined—and may never be defined—so as to permit an unambiguous, objective measurement of the dollars spent for basic research in this country.
>
> Definitions of basic research in terms of such factors as the degree of freedom with which the investigator works and the prospective applicability of his findings are useful in making administrative decisions on the support of research. In practice, administrators do not decide to support work because it is basic or not basic. Indeed, the term "basic research" is used much less frequently in the day-to-day business of research administration than it is in communicating with the nonscientific world. Administrators consider the man—his past performance as judged by his peers—even though the merit of the research project is ostensibly the basis for judgment. They consider the facilities available to him. They take into account the support available in his field—whether it is a "gap area" or one well financed. What those who make decisions cannot do and do not attempt to do is to judge the intentions and the motives of investigators. Definitions of "basic research" in terms of motive and intent are, in practice, used by administrators—those who participate in decisions on the distribution of research funds—neither in administering research nor in collecting statistics on research.

The NIH is very much in accord with the views of Dr. Kidd in respect to the utility of distinction between basic and applied research in administering science programs. Therefore, in the operation of NIH programs no such distinctions are made.

The NSF in collecting statistics from Federal agencies on their expenditures for basic research defines "basic research" in terms of the motives or intent of the individual investigator. In responding to NSF the best estimates possible are made of the distribution of expenditures in accord with these definitions. Under these circumstances, NIH expenditures reported in the "Federal Funds for Science" series reflect a consistent pattern of approximately one-third basic and two-thirds applied.

(*b*) When NIH support for research is viewed in terms of scientific content rather than the intent of the investigator, we estimate, that two-thirds for fundamental research in support of NIH missions and programs and roughly one-third applied research. We regard this ratio as a reasonable one for the present. Looking ahead, as greater effort is devoted to costlier applied research opportunities; e.g., bioengineering, organ transplants, vaccine development programs, this balance may be modified somewhat but not at the expense of fundamental inquiry essential for the advancement of the Nation's health through research.

(*c*) In specifics, no. In general, support for the conduct of academic science should grow at the rate necessary to sustain the present body of ongoing science in light of increasing substantive and economic cost factors and provide for the support of the new investigator emerging from training programs and general institutional needs related to strenthening the scientific environment and resources of the institution.

(*d*) NIH long-range plans are to expand support for fundamental research in all fields of science directed toward the development and use of scientific knowledge in the following areas:

1. The causes, diagnosis, treatment, control, prevention of, and rehabilitation relating to the physical and mental diseases and other killing and crippling impairments of mankind;
2. The origin, nature, and solution of health, problems not identifiable in terms of disease entities;
3. Broad fields of science where the research is undertaken to obtain an understanding of processes affecting disease and human well-being;
4. Research in nutritional problems impairing, contributing to, or otherwise affecting optimum health;
5. Development of improved methods, techniques, and equipment for research, diagnosis, therapy, and rehabilitation.

Growth should be related to social needs, scientific opportunities, and the availability of human and physical resources. The pace of growth should be responsive to the interplay of these critical variables rather than Procrustean formulas. In these terms present estimates suggest an increase in national expenditures for medical research (both public and private) from $1.9 billion in 1965 to $3 billion in 1970.

6. In your judgment should NSF give greater support to the basic research activities of the nonprofit institutions as well as the universities?

6. Although the broadest base of fundamental activity exists either in universities or university-related institutions, the National Science Foundation has supported from the beginning of its activities, many other private nonprofit research organizations or laboratories, most notably inland field stations and marine biology laboratory facilities, some of these offering entirely unique opportunities for specialized research. Certainly, any expansion of NSF support should encompass such institutions as well as the universities. The balance of the support should be related to the need and it would seem unwise to attempt to tie it to any fixed formula or proportion.

7. Is consideration given by NIH to the geographical distribution of research grants?

7. The National Institutes of Health is a mission-oriented agency. Its statutory objectives are the solution of the major disease problems confronting mankind and advancement of knowledge relating to disease, the nature of the underlying biological processes, and the means and methods for the most effective diagnosis, treatment, and prevention. In this context the role of NIH in the support of science is derivative of the primary objectives set forth above. Consequently, the principal determinants bearing upon selection of research projects for support through grants are (1) the scientific merits of the proposal and (2) the relevance of the proposed research to the overall mission objectives encompassed in the NIH programs. An important objective of NIH activity, however, has been the strengthening of the national system of medical research and research training and the enlargement of the capability of the Nation in the areas of scientific and academic activity important to the advancement of the Nation's health. Thus in a variety of ways NIH programs have contributed to the growth of institutions throughout the country. This has enlarged the number and distribution of scientific centers in the biomedical area and improved the national distribution of research and research training in the biomedical field. This effect of NIH activity is not the result of deliberate decisions based upon geographical considerations but upon judgments arising from the framework of NIH scientific advisers on the institutions and programs of potential throughout the country. The result has been an ever-widening geographical dispersion of biomedical research activity in the United States. It is a consequence of qualitative judgments rather than geographical objectives.

8. It is apparent from the hearings that NIH differs markedly from NSF in its responsibility for in-house laboratories. Could you comment on the role of such laboratories and their future in relation to Federal support of extramural research?

8. Although the intramural and extramural components of the NIH programs are, in many respects, independent activities, the grant-in-aid programs derive considerable benefit from being administered by an organization that has recognized competence and long experience in the conduct of both laboratory and clinical research.

The relationship of NIH intramural scientists to the extramural programs is usually informal. The NIH scientist is no more likely than his university counterpart to be appointed to a study section or other advisory group because a deliberate effort is made to give the membership of the review groups a wide geographic distribution (in

order to draw on all segments of the scientific community and to facilitate site visits). The intramural staff is however, frequently consulted on program problems and asked for information and advice on the varied technical questions that arise during the review of grant applications and in the course of policy and program discussions involving the substance of scientific research. The volume of such informal consultation is largely undocumented but is high enough to elicit occasional complaints from the scientists that too much of their time has to be spent in this way.

As it is no longer necessary for the NIH grant programs to be mainly focused on building up the national research base, more attention is being given to the deployment of effort in the support of specific research and developmental goals for which sophisticated scientific guidance is indispensable. As a result, there is now a need and an opportunity for developing a comprehensive institute approach to each of NIH's categorical missions in which the intramural and extramural programs will become increasingly interdependent. Several institutes—notably the National Cancer Institute—have already taken steps to involve their intramural staff on a more formal and continuing basis in the development of institute policy. This trend will clearly continue.

The growth of collaborative programs is an important feature of this evolution. Such cooperative ventures can play a most effective role in bringing a massive and coordinated research attack to bear on specific disease problems and are essential to major developmental research projects in such complex fields as bioengineering, large-scale biometric and epidemiological studies, the application of automation techniques to laboratory and clinical procedures, and the development of artificial organs and supportive devices. In activities of this kind NIH must depend heavily on the competence of its in-house scientific staff.

The scientific staff is also a useful reservoir for the recruiting of scientist-administrators for NIH and, indeed, for other parts of the Public Health Service.

The intramural activity makes another significant but subtle contribution to the extramural programs which is at least as important as the direct assistance it provides. The role of NIH as an outstanding research institution pervades the Bethesda campus and provides a setting that has imperceptibly, but nonetheless profoundly, influenced the development of the whole organization. The prestige conferred on the whole of NIH by the eminence of some of its scientific staff and the solid base of experience provided by NIH's direct involvement with the leading edge of research has won for it an acceptance—by the scientific community, by the public, and by the Congress—which it could not have achieved—and would not be able to maintain—as merely a Government agency charged with responsibility for the disbursement of Federal grant-in-aid appropriations.

9. The point has been made during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency X, agency Y, or both. More specifically:

(a) What guidelines or criteria has NIH established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the agency's jurisdiction and, therefore, should, or should not, be supported by NIH?

(b) If written criteria have been established by NIH, please submit a copy thereof to the committee.

9. As the major Federal granting agency providing support for research on health-related problems, the Public Health Service has published general guidelines describing the types of proposals, including the scientific areas considered relevant, which are deemed pertinent to the mission of the agency. Because of the potential breadth and diversity of fields of science from which significant information may be derived as contributory to a better understanding of health and disease, these guidelines are necessarily broadly drawn. They were described in sections I and II of the widely distributed document, "Public Health Service Research Grant Programs"; these guidelines form sections A, 501, and 502 of the current "Grants for Research Projects, Guide to Operation Procedure." Although now adapted for use relative to all research grant programs administered by elements of the PHS, these provisions originated within the NIH during the period when that organizaion was the sole research granting element within the PHS. With appropriate modifications related the establishment of granting authority within the Bureau of State Services concerning research in the areas of community and environment health, they still describe the general parameters of the NIH research support activity.

It should be further noted that, in the formative years of the NIH and NSF grant programs, discussions of an informal nature were held between operating level officials of NIH and NSF concerning instances of possible program overlap in scientific areas of potential interest to both agencies. The field of chemistry represents an excellent example. It was decided that proposals in medicinal chemistry would be accepted by the NIH whereas those oriented more toward the fundamentals of chemistry per se, such as the nature of a chemical reaction, would be accepted by the NSF. Discussions between potential grant applicants and program officials of either agency have resulted in widespread awareness of this guideline which has stood the test of several years of experience. If the NIH does receive a proposal seemingly more appropriate for funding by the NSF, the application may be returned without further processing with advice that the applicant seek support from the NSF.

The general philosophy which characterizes the NIH attitude in this matter recognizes the difficulty in defining precisely any line of demarcation and the danger to productive program development which might occur if any such line should be drawn too rigidly or arbitrarily. Thus a reasonable degree of program overlap is permitted without distorting the mission of the NIH or creating competition between NIH and NSF.

10. Are you satisfied with the ratio of support between NSF supported research and its efforts in regard to education?

10. NSF bears this responsibility for assessing the adequacy of the current balance between its support for research and for education. NSF has, from the beginning, been sensitive to the need for balance among its programs. In so doing, NSF has contributed significantly to the advancement of science education at all levels as well as to the support of basic research. Looking to the future, it seems reasonable to anticipate that the exanding programs of the Office of Education may enable NSF to increase the existing ratio in favor of basic research.

11. How does NIH coordinate its educational support with NSF, NASA, the Atomic Energy Commission, the Office of Education, and other Federal agencies involved?

11. At the present time, the agencies offering the bulk of Federal support for science or training in higher education institutions depend mainly on informal coordination. This coordination generally takes the form of information exchange—on either common-interest problems or institutions. Informal liaison arrangements also are common. The effectiveness of these coordinating activities varies with the particular programs undertaken and with the various agencies. From these activities, a number of joint funding arrangements result, as well as many referrals of project requests from one agency to another.

An informal interagency group meets semiannually to work out agreements on stipends and fellowship support levels. These meetings have been chaired by the NSF representative; it is anticipated that this task will be shared on a rotating basis in the future, drawing upon representatives from NIH and the Office of Education, respectively. Other informal and formal coordinating arrangements are even more fully developed in the facilities program area. NASA, AEC, NSF, and NIH have been actively engaged in information exchange on requests from various institutions for research renovation or construction of research facilities of one kind or another; and a representative of NSF (as required by Public Health Service Act) sits as a member of the Health Research Facilities Council that reviews requests for NIH support for facilities constructions. With the initiation of the Office of Education's education facilities program toward the middle of fiscal year 1965, the Office of Education called together facilities program representatives from NSF, NIH, and NASA. These met in an ad hoc group for a series of discussions of common problems and distinctive approaches in the facilities program area. Out of these ad hoc meetings (that were held monthly from January through May) came a tentative proposal for a formal interagency working group. This group—if established in proposed form—would advise the Federal Interagency Committee on Education on what progress could be achieved toward common education goals through voluntary interagency cooperation and information exchange. The nature and responsibilities of this proposed interagency group are still under discussion.

12. Are the NIH institutional grants consistent in policy and content with those of NSF, NASA, and other Federal agencies? What lessons has NIH learned from its institutional program that may have relevance to NSF activities?

12. The general research support grant program of the National Institutes of Health while generically an "institutional grant" is restricted for support of health research and research training.

The stimulus for the general research support program had its origin in the postwar growth of the NIH's extramural research support programs and the effects of this growth upon recipient institutions. The research and research training programs of NIH and other Federal agencies had grown to a point where their size and scope exerted a profound influence upon the medical schools and other institutions within which individual investigators work. The GRS program came into being to provide support of research and research training in a way that would not only meet the needs of the individual investigator but would assure the medical schools and other institutions engaged in health research an effective and responsible role in determining the use of a portion of the total Federal funds distributed to them to support biomedical research and research training activities.

In recognition of the importance of meeting institutional needs for control of their own biomedical efforts, policies for the GRS program have been established which encouraged institutions to exercise local initiative and discretion in meeting emerging opportunities in research, in exploring new and worthwhile scientific ideas, and in using research funds in ways that will contribute to long-range institutional development for the improvement of research and the research environment. Included in the goals of the program are (1) stabilization of key research personnel; (2) support of new or exploratory research projects not yet at a stage to compete successfully in national competition for NIH project funds; (3) support of central, institutional resources such as computer centers and animal facilities.

The general research support grant of NIH is generally consistent in policy with those of NSF and other Federal agencies. However, important differences in content do exist in keeping with the restricted mission of the supporting agency. Thus, the primary difference is that NIH restricts the use of its funds to the support of health research and research training activities, but in so doing is able to provide support for a broad range of basic as well as clinically oriented studies. The NSF funds on the other hand are available for the support of scientific fields which are completely unrelated to biomedical research and research training.

Another difference exists in terms of the types of institutions which receive institutional grants; NSF institutional grants are awarded only to universities and colleges, whereas general research support grants provide support to hospitals, research institutes, and research foundations as well as to the individual health professional schools. In 1964 NSF excluded medical and other health professional schools from eligibility for separate institutional grants. It is to be noted that in accordance with the expressed intent of the Congress, the NIH plans to extend general research support to universities and graduate schools this fiscal year.

In administering its program the NSF bases its awards solely upon the research dollar investment which that agency has in an institution, in contrast to the NIH program which has established a formula that recognizes both the Federal and non-Federal support of the health research programs in the institution. The NSF thus has been able to

develop a simplified procedure whereby the institution requests funds and the agency awards them on an almost automatic basis. The differences mentioned, however, have led the NIH to establish a more detailed scientific review and evaluation procedure for its institutional grant program. In its application for GRS funds the institution must (1) list its expenditures for research provided from "outside" sources, (2) provide a statement specifying the manner in which the institution intends to use the grant for furthering its health-related research and research training activities, and (3) provide a statement specifying the practices the institution intends to employ in meeting its responsibility for rendering scientific judgments and discriminations in the allocation and administration of the grant. Whereas review of applications is a staff function at NSF, the GRS program includes staff review of applications followed by a review by a Scientific Review and Advisory Committee composed of eminent administrators and scientists from foundations, research institutions, universities and hospitals, who furnish independent viewpoints on the merits of supporting any particular institution. The objectivity, technical competence, and heterogeneous composition of the Committee, together with the yearly replacement of a portion of its members, help assure that different aspects of health research and health research training receive critical and continuing review. Subsequent to review by the Committee, each application is presented for further review and consideration to the National Advisory Health Council, which in turn makes final recommendations to the Surgeon General.

Unlike the NSF program, under GRS policy each academic grantee receives a base grant of $25,000 plus an additional amount determined by application of the established formula. Schools of medicine, dentistry, osteopathy, and public health have been and presently are considered to be automatically eligible to receive GRS awards. Other types of health professional schools and all other nonacademic health research organizations must meet established criteria before an award can be made.

In reference to the manner in which institutional grant funds may be used for the support of scientific activities at institutions, under the NSF program grantees are allowed to use funds for construction and alterations and renovations, whereas the GRS program proscribes use of funds for these purposes. With this exception, the manner in which funds may be expended under both the NSF and the NIH institutional grants programs are quite similar.

It has been the experience of the NIH through its General Research Support program that appropriate scientific review and evaluation both of applications for institutional support and of the resulting impact which that support has produced in the recipient institution is important to the long-range development and success of the program. Also, it is believed that the establishment of a base grant or a minimum grant for academic grantees has been instrumental in making the program a meaningful mechanism in aiding the institution to improve and extend existing programs and to introduce new kinds of biomedical research and research training activities which are essential to the continued progress of the health sciences.

13. Would you explore the issue of the project grant to an individual investigator, versus the institutional grant? What is the

proper balance between these two systems, now and in the future? Will the new science development programs relieve the need for project grants at these institutions?

13. The project grant in our opinion and in our experience, and in the opinions of every group which has deliberated on this question. has been regarded as a uniquely successful instrument for the support of either biomedical or fundamental (i.e., basic science) research in the partnership between either the Federal Government or some other agency or philanthropic organization and the investigator. There seems little serious question that this method of supporting research gives the best possible assurance that funds will go to the study of the most promising ideas by competent investigators working in adequate facilities. To some degree, it is the success of this means of research support which has been responsible for the emergence of other needs which cannot entirely be met by it. It was in an attempt to meet some of these needs that the general research support grant was developed. They include the following:

1. Support of preliminary exploration of new ideas insufficiently developed to be adequately marshaled in project applications.
2. Support of promising new leads immediately without the delay inherent in project applications.
3. The bridging of inevitable gaps in project support.
4. Temporary support of new staff members who have not yet had the opportunity or the time to obtain project support.
5. The providing of central institutional facilities or resources serving a variety of enterprises and investigators.
6. Support as needed for the necessary internal balancing and strengthening of the organization.
7. Other special local needs related to the overall strengthening of the research effort but in many instances not project oriented.

The general research support grant as a form of broader institutional support was thus developed in support of these and other needs. A relatively brief experience with this mechanism of support has encouraged us to believe that although the project grant should continue to be the backbone of our research support effort that the general research support program should not only be continued but expanded to provide greater flexibility for the expansion of the scientific base of research programs, both by recipient institutions and by us. Specifically, it seems desirable to use the general research support authority not only to the full degree authorized by statute but to extend this authority to support the planned development of biomedical research and training programs of institutions and to enlarge the number of such centers of excellence. It would seem desirable to free at least this portion of such authority from any fixed relationship to existing programs. It will be seen, therefore, that the balance between the two types of support is an evolving one which is still in evolution and should probably so continue as a dynamic force to support the changing needs of the biomedical and scientific community. Within this overall view of the relationship of the two kinds of support, it becomes clear that the new "science development" grants of NSF will, by broadening the base both by number and geographical distribution of centers of excellence in science and engineering for scientific training,

undoubtedly eventually increase the demands by scientifically trained personnel for additional project grants as this additional trained manpower pool becomes distributed both in new and established centers of scientific investigation, rather than in any sense relieving a need for project support.

14. You referred to the statistical data collected by NSF. How up to date, complete, and accurate do you consider this material to be?

14. I believe, as explicitly noted in my statement before the committee on July 14, 1965, that:

The NSF function in measuring and analyzing the quantitative and economic characteristics of science and its resources is basic to formulation of programs and policy.

This function was initially undertaken by NSF in its Program Analysis Office through a series of comprehensive benchmark surveys in 1954 concerning all sectors of the research economy—Government—industry—nonprofit. In the two largest sectors, the Federal Government and industry, these surveys have been repeated annually, and expanded in scope. In other sectors, e.g., nonprofit institutions, the surveys have been repeated at benchmark intervals about every 4 years. Periodically, NSF publishes a transfer table showing the flow of funds from source to performer and providing national totals for each. During this period, NSF has steadily improved its statistical data—more up to date, more complete, more accurate.

The potential utility of this basic statistical series concerning the Nation's R. & D. effort could be greatly enhanced by publication of national totals for the current year, e.g., 1965, in 1965. There is, of course, an element of risk in publishing national totals, when some components must be based upon estimates. Nevertheless, the potential utility, in my view, far outweighs the risk.

The utility of NSF statistical data on the Nation's R. & D. could be significantly improved by inclusion of figures on capital outlays for R. & D. plant and related facilities. The information now provided on the national research and development effort is limited to data reflecting current operating costs; the considerable investment by all sectors in construction of research facilities is lost sight of; the series should be expanded to provide data to measure the effectiveness of programs in maintaining and expending the required physical research resources.

With respect to the considerations of completeness and accuracy, I concur with the excellent statement of Dr. Harvey Brooks, dean, Division of Engineering and Applied Physics, Harvard University, with respect to performance and problems.[1] In addition to the problems mentioned in his statement, I would add only one: How to categorize State universities and other public institutions of higher education? Functionally, they are educational institutions; in our system of national accounts, e.g., GNP, they are encompassed within the public sector. NSF's current practice is to encompass all educational institutions in the nonprofit sector and to treat State appropriations for the support of State universities and colleges as "institution's own funds," when such funds are expended for the support of research. In my

[1] Statement prepared for submission to the Subcommittee on Science, Research, and Development of the Committee on Science and Astronautics, U.S. House of Representatives, 10 a.m., July 14, 1965.

view, this practice seriously understates State support for research. This understatement is of little concern at the microlevel, when swallowed up in a national total of $21 billion for R. & D. Nevertheless, at the microlevel, current statistical practice yields a misleading estimate of State funds expended for the support of research—perhaps by an order of magnitude. With public institutions predictably increasing as a proportion of all higher education, this disparity between actual State support and that reported by NSF will continue to grow unless some corrective action is taken.

15. Exactly how do you make use of the Science Information Exchange?

15. The National Institutes of Health has over the years prior to and since the formation of the present Science Information Exchange maintained a deep interest in fostering, promoting, and supporting the aims and functions which the Exchange performs. This interest has been maintained because of the recognition of the need for a interagency source of information on ongoing research programs that have a variety of sources of Federal support. Such a source has acted as a valuable management tool in planning and maintaining research support operations.

HISTORICAL INTEREST IN SIE

The National Institutes of Health provided the historical origins of the present Exchange in an early (1946–50) Information Exchange Section in the Division of Research Grants. As voluntary contributions of information on medical sciences programs from other agencies grew, the interagency scope was recognized and formalized by Federal agency agreements into the Medical Sciences Information Exchange and organizationally transferred from NIH to the National Academy of Sciences, National Research Council in 1950 to enable it to serve the wider information needs of the Federal Government. The NIH has continued during the subsequent years to help the Exchange in its purposes by providing funds through grants and memorandum agreement transfers and has furnished leadership in its governig bodies during its various organizational transformations and name changes to its present state under the National Science Foundation and Smithsonian Institution auspices.

SCIENCE INFORMATION SERVICES TO NIH

The NIH has cooperated fully in supplying SIE with information on its extramural and intramural research operations and has found a profitable return for the investment. The SIE provides certain selected services for the NIH by acting as a central repository for information on currently supported research projects and for those which have been terminated over the past 10 to 15 years.

RESEARCH PROJECT SUMMARY SHEETS (NOTICES OF RESEARCH PROJECTS)

Preliminarily to the meetings of the initial review groups (study sections of the NIH) SIE compiles and makes available booklets of one-sheet summaries (NRP's) for all proposals to be reviewed by each study section. The booklets include summaries of proposals for NIH

support and summaries for projects already supported in the applicant's name by other agencies and private foundations when known. Study section members use these to avoid multiple support of the same research project and to aid in their knowledge of parallel work going on in the laboratory of the investigator.

The NRP serves as a document for analysis, storage, retrieval and distribution of research information to many other offices of the NIH. As a recurring service, SIE circulates to offices such as Research Documentation Section, Research Grants Review Branch and Career Development Review Branch of the Division of Research Grants copies of all NRP's from submitted research projects that are approved and paid. SIE also maintains and will provide on request a list of NRP's on intramural research projects conducted within the laboratories of NIH.

REQUESTS FOR SCIENTIFIC AND ADMINISTRATIVE INFORMATION

Information on the scientific research supported by sources outside the NIH is readily available through the Exchange and has been sought on a number of occasions. There are a number of examples of research topics, e.g., radiobiology, reproductive physiology, marine biology, veterinary medicine, pesticides for which the NIH has had need to make intergovernmental evaluation of support (dollar amounts and numbers of projects) as a data source for manpower and resources analysis. A listing of such types of requests made by NIH personnel and furnished by the SIE over a 5-month period in 1964 is attached to illustrate the search request services provided by the Exchange. The Science Information Exchange system of coordinate classification is unique to any other existing in the Government and permits retrieval of broad scientific topics that have been needed by NIH and were not accessible from other information services.

As an additional service SIE may be asked to retrieve information and documents for terminated projects across NIH Institutes lines and intergovernmentally in many different contexts.

SUMMARY

The NIH has found the Science Information Exchange to be a continuing source of needed information on the support of specific research areas, on the support of specific scientific investigators and by providing data on broad research program areas that are supported by NIH, other elements of the Public Health Service, by other Federal agencies and by private foundations. It is hoped that the recent developments of a combined reporting system agreement between the Department of Defense and the National Aeronautics and Space Administration will provide input to SIE from their programs to make SIE coverage virtually complete for all significant performers in biomedical research.

Through its beneficial experience with the SIE, the NIH strongly supports its continued development as a central national source for substantive information on ongoing scientific research programs supported by Federal programs and private agencies.

REQUESTS MADE BY NIH [1]

(From January to May 1964)

Division of Biologics Standards:
138 Current studies on Mitomycin C, and bacteria and mammalian in vitro.
Mrs. A. K. Reich, Scientific Communications.
170 Photodynamic action in biology.
Mrs. A. K. Reich.
597 SV 40 viral nucleic acids.
Dr. Bernice Eddy.
Division of Radiological Health:
584 Lasers and masers in biology and medicine.
Dr. Paul Hahn.
Division of Research Grants:
76 Data processing related to manpower or training.
Mr. Werner Matteradorff, Statistics and Analysis Branch.
867 Studies on populations which have low incidence of disease.
National Institute of Allergies and Infectious Diseases:
249 The number of virological research laboratories conducting active research.
Mr. George S. Yee, Research Reference Reagents Branch.
National Institute of Child Health and Development:
519 Nonsurgical treatment of hydrocephalus.
Dr. Donald Robinson.
751 All support of meetings in the life sciences area.
Miss Ruth Crozier.
851 Human communication.
Miss Ruth Crozier.
1042 All grants to departments or schools of optometry.
Mrs. Lillian Freedman.
National Institute of Dental Research:
428 Listing of Veterans' Administration projects, by given accession numbers.
Dr. Edward J. Driscoll, Clinical Director.
National Institute of Mental Health:
87 All studies on suicide.
Dr. James Fox, Special Assistant to the Deputy Director.
317 Psychological and social factors related to smoking.
Mrs. Lillie Theobald.
460 Studies on psychiatric nursing.
Dr. Morris C. Leiking, National Clearinghouse for Mental Health Information.
541 Alcohol preference in white rats.
Dr. J. F. Pilgrim, Research Grants and Fellowships Branch.
556 Alcoholism and drug addiction.
Dr. Nathan Rosenberg, Research Utilization Branch.
585 Social maladjustment of adolescents.
Dr. George V. Coelho.
National Institute of Neurological Diseases and Blindness:
61 Epidemiology of optic disorders. Studies on or involving human twins.
Dr. John T. Schwartz, Epidemiology Branch.
304 Acceleration or deceleration injuries to the cervical spine.
Mr. Julian Morris.
753 Neurological bases of reading disorders.
Miss Sylvia Kesinger.
470 Fitting contact lenses to animals.
Mrs. Frances Dearman, Neurology Information.
426 Studies in which monkeys are used in investigations related to cerebral palsy.
Dr. Gilda Marques, Perinatal Research Branch.
769 Molecular biology studies supported by NINDB.
Miss Lois F. Hallman.
816 Cytogenetic studies of prisoners; cybernetics of human development.
Mr. Bob Schrieber.

[1] Listing incomplete. Prepared May 11, 1964.

National Heart Institute:
11 Cause and cure of cancer and congenital anomalies.
Dr. Sheila Mitchell.
451 Lipid research.
Dr. William H. Goldwater, Special Research Projects Branch.
985 Research and development of artificial implatable hearts and kidneys.
Mr. Philip Janus.
National Library of Medicine:
314 Manipulation of spine from an osteopathic or orthopedic point of view.
Miss Virginia MacDonald.
Office of International Research:
569 Stevioside or steviol.
Mr. Harry L. Hornback.
Office of Publications and Reports:
834 Studies on ethno-botany.
Mrs. Lillie Theobald.

16. Do you see important analogies between medicine and engineering that might guide NSF research and education in engineering?

16. National Science Foundation policies and programs providing support for research and education in engineering have evolved during the past 15 years, with guidance from the National Science Board. During this period, National Science Foundation has been sensitive to the advice of the scientific community, the science adviser to the President, the National Academy of Science, the newly established National Academy of Engineering, and the 11 professional societies representing some 900,000 engineers.

As indicated in the National Science Foundation's publication, "Scientific and Technical Manpower Resources" (p. 86), 46 percent of the engineers hold no academic degree, 47 percent received a bachelor's degree, 6 percent a master's degree, and 1 percent hold the Ph. D. In contrast, virtually all M.D.'s receive a minimum of 4 years' training in medical school beyond the baccalaureate level. The training process continues through internships and residency—an additional 4 years of formal preparation on the average. Because medicine and engineering vary so widely in the nature of their training, their functions, their career patterns, and the social and institutional settings in which they work, it is difficult to see how analogies might guide the National Science Foundation.

However, as a member of the Gilliland Panel and a consultant to the Science Advisory Committee, I have heard many lucid presentations discussing engineering research and education needs. The Director, National Science Foundation, in concert with the National Science Board, the Office of Science and Technology, and the scientific and engineering communities, bears the responsibility for judging how the National Science Foundation can contribute most effectively to meeting these needs.

17. From the standpoint of objectives, program content, and management, which of NSF's programs do you consider to be the best, and which do you consider to be the least effective? Also:

(a) What are NSF's notable weaknesses or deficiencies, and how may they be corrected?

(b) What more could the Foundation do to promote the progress of science?

17. The National Institutes of Health does not have the necessary information—nor would we presumed—to identify which NSF programs merit "best" or "worst" descriptors in terms of program content or management. However, in terms of program objectives, value

judgments are possible and probably even appropriate. From the point of view of NIH, we see one imperative function for NSF: that it, providing for the stability, vigor, and balanced growth of academic science. NSF—alone among Federal agencies supporting science—has the broad statutory role in science and science education that makes feasible the successful carrying out of that function. Those programs that contribute to this end—and the great majority of NSF programs certainly do—are the ones that NIH would like to see strengthened and expanded from year to year with the overall objective of assuring continued world leadership for American science capabilities. However, we have noted with some concern the tendency of NSF to pick up responsibility for direction and management of certain large-scale projects such as Mohole, radio astronomy, and weather modification. Mainly, NSF took on responsibility for these projects because they did not fit neatly within the scope of concern for any of the mission-oriented agencies, at the time the research need was perceived.

It is recognized that these large national enterprises are essential on the national science scene. They are particularly valuable when they afford a setting for postdoctoral or interdisciplinary training not available and not feasible to provide at individual universities. But we would not want to see these programs grow at the cost of limiting NSF's ability to expand in its pivotal role in support of academic sciences. Because of the complexity of these major science projects, they must be expected to exact a fairly high proportion of top management and scientific attention at NSF, irrespective of the original program intent. In our view, it would make sense to consider alternative management arrangements for these major projects. If national science objectives in the next 10 to 50 years are to be attained, NSF must be free to direct maximum energy and resources upon the strengthening of academic science, taking into account the strong complementary endeavors of other agencies such as National Institutes of Health and the Office of Education.

18. Has NIH been participating in policy and program planning in education under the new Federal Education Council?

18. The new Federal Interagency Committee on Education, established by Executive Order 1185, is chaired by the Commissioner of Education and includes a representative from each of the following agencies: The Department of State, the Department of Defense, the Department of Agriculture, the Department of Labor, the National Science Foundation, the Atomic Energy Commission, and the National Aeronautics and Space Administration.

As indicated in the response to question 11, along with representatives of NSF, NASA, and the Office of Education, NIH has been intimately involved in development of a tentative proposal for a formal interagency working group which, if established in its proposed form, would advise the Federal Interagency Committee on Education on what progress could be achieved toward common education goals through voluntary interagency cooperation and information exchange.

Because of our substantial support for health research, training, and the development of resources for the future in the Nation's scientific and educational communities, it is anticipated that NIH will be called upon to provide staff assistance and to participate, as requested, in the activities of the new Federal Interagency Committee on Education.

RESPONSE BY DR. AUGUSTUS B. KINZEL, PRESIDENT, NATIONAL ACADEMY OF ENGINEERING, TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

---

1. Do you believe it would be useful to amend the National Science Foundation organic act in order to more clearly express a congressional intent for increased attention to research in engineering?

1. I do not believe it would be useful to amend the National Science Foundation organic act in order to more clearly express a congressional intent to increase attention to research in engineering. I believe the purpose can be effected by budgetary scrutiny and emphasis to the Director.

2. It is our understanding that from 20 to 30 percent of the work done by the so-called nonprofit agencies—such as the Battelle, Armour, Stanford, and Midwest research institutes—actually is devoted to engineering that is of a basic nature. Would it not be useful to provide some support for this work through NSF?

2. Support for engineering research of a basic nature should be and is one of the functions of the National Science Foundation. Whether or not the nonprofits should be supported in this area by the National Science Foundation should be determined by the worth of the individual projects which they might propose.

3. In your testimony on July 15, you indicated that the present balance of support between basic research in the physical and life sciences and research in engineering is not satisfactory. What can be done to improve it?

3. Your committee should make it clear that the word "Science" in "The National Science Foundation" includes engineering science and the National Science Foundation should act accordingly. Specifically, the suggestions given in response to item 1 apply here.

4. Considering both that the Department of Defense finds it is supporting about 70 percent of the engineering research on campus and the often stated argument favoring plural sources of Federal support for basic research, what role should the Foundation have in financing research in engineering and engineering education?

4. The Foundation should explore certain projects which are not mission oriented or where the mission does not belong to any specific agency. The aid to engineering education should follow the same principles.

5. What would be the advantages and disadvantages of having the Foundation employ the Academy of Engineering as an operating contractor for undertakings in applied research for which Federal facilities are desirable?

5. There are many projects in which the National Academy of Engineering, and correlatively the National Research Council, could act as an operating contractor for the National Science Foundation. The

prime advantage would be the consideration of the overall problem by dedicated people of eminence, having both knowledge and experience in the specific field. The only disadvantage of which I am aware is that the National Science Foundation would have a less tight control and this might prove to be an advantage in many cases.

6. In your judgment should the engineering profession have more representation in our legislative bodies? If so, what might be done to attract more engineers and scientists into politics?

6. In my judgment the engineering profession does not need representation as such in legislative bodies but it is highly important that members of legislative bodies have education and understanding with respect to engineering. Presently many corporations encourage their people to get into local governmental affairs. I am confident that this is a situation where the country is willing to help those who are helping themselves but that the initiative must come from the individual. For the future I think the most important thing is to have all of our young people given a series of basic science courses so that they are better able to understand the world in which they will live.

7. Considering the Foundation's responsibilities for training and education of scientists and engineers and its interest in the supply, demand, and utilization of this manpower, what responsibility should the Foundation have in studying or doing something about retraining of scientists and engineers whose scientific specialties have become obsolete?

7. There are a great many moves in various directions with respect to "retraining of scientists and engineers whose specialties have become obsolete." I know of no major industrial-education center in the country where opportunities lack. Here again, the problem is to provide incentive to the individual. I think the National Science Foundation might well offer special scholarships for this purpose and might well give grants in support of many of the existent "retraining centers."

8. It has been alleged that some applied field projects that are in the national interest fail to gain support because each agency gives such a project a low priority, although the aggregate of these multiple requirements might warrant a higher priority. What is your opinion on this?

8. Without a specific case in hand it is difficult to directly address the question in No. 8. I presume what is meant is that a subject of importance falls between the slots in the agencies because it is not sufficiently important to any single one of them. It would seem that the Federal Council or the PSAC office could direct such projects to a proper home and that the National Science Foundation should in many cases be the coordinating and supporting agency.

9. What are your views as to the appropriate balance in the conduct of basic research as between universities, the Federal Government, and industry?

9. Basic research should for the most part be conducted in the universities and truly nonprofit research institutions. However, it should be recognized that certain basic research is necessary for the tone, morale, and coupling of any laboratory or organization so we will and should always find an appreciable amount of basic research in industry and mission oriented government laboratories. This should

be considered as an important part of the whole but it should be understood that neither industry nor mission oriented government laboratories should have the prime national responsibility for carrying on basic research. Having said this I would emphasize that financial support for university and nonprofit research organizations who do have the responsibility for the basic research program of the Nation must come from either Government or the general public through direct donation. The latter being as uncertain as it is, the role of the Federal Government in providing financial support is obvious.

10. What proportion of the engineers should have the Ph. D. degree?

10. The question regarding the number of Ph. D. engineers can best be answered by "the more the better." Timing is important. Fifty years ago most chemists who contributed to the science did not have Ph. D.'s. Today there are almost no chemists who have contributed importantly who do not have a Ph. D. degree or equivalent. Given a standard of intelligence and drive the greater the education and training, the more apt is the individual to contribute. If we would assume that the top 10 percent should have this type of education and training and if we assume that there are some 750,000 truly professional engineers in this country, we should have 75,000 Ph. D. engineers. As I understand it, we are so far from this figure that my original reply "the more the better" is the really practical answer.

RESPONSE BY DR. J. HERBERT HOLLOMAN, ASSISTANT SECRETARY OF COMMERCE FOR SCIENCE AND TECHNOLOGY, TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

1. What in your judgment should be the relative magnitudes of Federal support for "mission-related" research and general or "free" research, such as that supported by the Foundation?

1. I do not think that any specific formula should or can be established for the Nation between "free" research and mission-oriented research. The magnitude will vary greatly from time to time and must depend upon many factors hard to quantify.

In my testimony of July 15, I stated my philosophy for division of responsibility as follows: "In my view, NSF should not take on responsibility for applying knowledge, or for operating development programs, except in the fields of education and science information."

At another point in that testimony, I said, "The National Science Foundation is a keystone in our efforts to develop the Nation's scientific and technological resources. Its long-term objectives should therefore be focused on the institutions of science, rather than on the solution of specific scientific questions."

The magnitude of mission-oriented research depends first on the public judgment of the importance of the mission. Then within the program authorized by the Congress, wise people must judge the technical opportunities for advancement, in competition with the operating programs that meet short-range objectives.

2. What criteria, in your opinion, are appropriate for the Foundation to use in selecting technical areas for support and determining the national needs for such research support?

2. Any scientific endeavor undertaken by an agency of the Federal Government should be judged objectively on criteria based on the aims of the agency.

In the case of the National Science Foundation, the criteria should be: Does work in this given technical area contribute to the understanding of the world in which we live? Does it foster the stability and growth of the scientific community? Does it produce better qualified scientific personnel? Does it build the institutions of science and technology?

The research supported by NSF should lead to a better understanding of the physical, social, economic, and political world. It should not be aimed at practical objectives of society.

Clearly, in one sense, the NSF work should support the missions of all other agencies' operating programs. Thus, the National Science Foundation should not undertake work which can be better justified by the precisely and properly defined mission of another Government agency.

The National Science Foundation has, in my view, three responsibilities:

A. To support, through projects or grants, the scientific work of individuals or teams of individuals. The adequacy of proposals submitted by scientists can best be judged by the scientific community. The scientific results of their work is the measure of success;

B. To support the establishment and growth of scientific and educational institutions throughout the Nation, to the end that education for science be freely available. The strengthening of resources is the objective;

C. To support certain fields of technical activity declared to be important by those who know the Nation and its social needs best.

For the first two responsibilities, unquestionably scientists meeting the highest standards of their peers are the only ones qualified to pass judgment on the merits of ideas and to allocate moneys. For the latter two, the scientific community must share the responsibility with others of society, as it is unlikely that scientists have an unique competence to make the judgment.

The criteria for the projects to meet the third responsibility should be: (1) Is the area of science now being overlooked but potentially of value to science and to society? (2) Is the area of scientific or technical inquiry of importance either in understanding man's institutions or the world in which he lives? (3) Are there inadequate resources being devoted to the field?

I emphasize projects falling into this category because the NSF has been predominantly concerned with selecting proposals submitted by scientists. It has underemphasized the work which relates to the understanding of new industrial, economic, or social worlds. It has concentrated upon the physical sciences.

3. Do you believe that gaps in applied research may exist between the different programs of mission-oriented agencies? Should there be a Federal mechanism for gap filling in this area as well as for basic research?

3. I am not aware of any significant gaps. Even if they exist, there is no need for "gap filling" by NSF. If NSF meets the three responsibilities described above and concentrates on a better understanding of man and his environment, the mission-oriented agencies will do the rest. Of course, this presumes that all agencies, including NSF, do the optimum amount of R. & D. proper to their missions, and that Congress supplies adequate appropriations.

4. In your testimony on July 15 you referred to basic industrial, economic, and social problems, stating "these studies should be carried out largely in universities where there is presently comparatively little activity." Is this latter statement really true? Our impression is that a good deal of such work is carried on within the universities.

4. Yes, it is demonstrably true. NSF's "Current Projects on Economic and Social Implications of Science and Technology, 1964" (NSF 65–16) lists only 405 projects, or about 4 times the number of the first annual inventory 6 years earlier. It lists projects at only 106 colleges and universities of the more than 1,500 senior colleges and universities in the United States. I call that "comparatively little activity."

Many millions of dollars are being spent by the various agencies of the Government, through the universities, in nuclear technology and atomic power. Similar substantial amounts are being spent in the sciences and technologies of materials.

NSF's support for technical activities related to industrial technology is only a few million dollars. Its support of economics—simulation and model making—is very small compared to its support, for example, of atmospheric sciences.

Look at the technologies of other fields: construction, transportation, communications, highway safety, city building, and the like. Federal expenditures in these fields are minuscule by comparison to nuclear and materials technologies.

Concrete figures are not readily available to document such a statement, but the *a priori* evidence is convincing. I would like to see an accurate survey of the amount of intellectual activity in the universities on the subject of transportation. I believe that it would amount to a few million dollars annually and would be totally unimpressive when compared to the size of the transportation industry and the scope of its problems.

Similarly, the amount of R. & D. conducted in the universities on the science and technology of building construction is insignificant. Yet transportation and building are among the most significant economic activities of the Nation.

Furthermore, the amount of R. & D. conducted in the universities on the subject of automobile accidents is also insignificant. Neither the appropriate Government agencies nor the universities have recognized the magnitude of the problem, despite the fact that 50,000 people are killed in automobile accidents each year. By comparison, polio, which killed a few hundred at its peak, aroused the sympathies of the American people, and a massive effort was undertaken to eradicate polio. Some of the polio money was from the private National Foundation, and some was public through the Public Health Service. Virtually all of it, from both sources, was spent through universities.

Those are some of the types of evidence which convince me that my original statement was true and continues to be true: There is comparatively little activity in the universities on industrial, economic, and social problems relating to technology. I believe that the NSF should broaden its concept of support of science to include greater support of science relating to engineering, technology, politics, and the economy. I further believe that greater support of science and technology by appropriate mission-oriented agencies in the less glamorous fields should be undertaken. Predominantly, the support of NSF should go to educational institutions that combine educational and engineering research functions.

5. It is our understanding that from 20 to 30 percent of the work done by the so-called nonprofit agencies—such as Battelle, Armour, and Midwest Research Institutes—is actually devoted to engineering that is of a basic nature. Would it not be useful to provide some support for this work through NSF?

5. The work supported by NSF should include both research and engineering. The Foundation should support research in the engineering sciences, especially where the funds contribute to engineering education. Only under exceptional circumstances should support

go from the NSF to nonprofit research institutes. The reason is that such institutes are not primarily concerned with education or training, and NSF should confine its attention to universities, which are.

6. How effective is the Federal Council for Science and Technology in presenting, to NSF, the needs of mission-oriented agencies regarding basic research and getting NSF action on such needs?

6. How effective is the Federal Council for Science and Technology of mission-oriented agencies through its various committee activities. I can speak from experience regarding activities respecting the atmospheric sciences. The NSF participates on that committee, considers, and evaluates the scientific and technical programs of the various agencies, in atmospheric sciences, and has modified its program of support not only to insure more scientific workers in the field, but also to broaden its institutional support. It has greatly assisted the development of the scientific literature of the atmospheric sciences. I am confident that the Federal Council also has been effective in presenting, to NSF, problems relating to scientific information and documentation and to oceanography, and NSF has responded by modifying its program.

7. You also said, "For the good of the Nation we must provide mechanisms that broaden participation in the decisionmaking process which determines the support of science and engineering." How do you propose that such mechanisms be provided?

7. The determination of criteria and granting of institutional support, as well as broad support, for these fields of science, must be accomplished through panels and policy boards that represent not only the community of science but also people with political, economic, legal, social, and other experiences.

In the best interests of science, two independent kinds of decisionmaking need to be recognized: (*a*) Decisions related to quality and significance of effort—these decisions are best made by scientists; and (*b*) decisions related to placement and growth of institutions and the broad support for fields of scientific inquiry—these decisions are best made by groups of wise men, including nonscientists. These latter questions of deep social significance require value judgments of the society broadly and should not be left wholly in the hands of scientists.

To this end I also believe that it is possible for Congress to establish mechanisms of review of the appropriations of the various agencies of Government to insure that support both by institutions and by fields of science are adequate and appropriate. More or less piecemeal methods of dealing with individual appropriation requests have tended toward a short-term view and a fragmented approach. While individual appropriations committees can and do provide effective checks and balances on individual mission-oriented agencies' activities, there is no way at present of dealing with the total scientific and technical effort in the perspective of the Nation's needs.

8. How do you distinguish between basic and applied research, and what proportion of total research funds do you feel should be devoted to each, in the context of the Department of Commerce's mission?

8. Applied research is that which clearly has an actual or potential application to meet minimum requirements of the particular institution that supports it. By basic research is usually meant that research whose purpose is to provide an intellectual resource which at a later

time may serve as the basis for application to specific requirements. Judgments of the differences between applied research and basic research, if such differences really exist, will always be subjective and will be largely in the eyes of the beholder. The generally accepted NSF definitions are: "Basic research is that type of research which is directed toward increase of knowledge in science. It is research in which the primary aim of the investigator is a fuller knowledge or understanding of the subject under study rather than a practical application thereof, as in the case with applied research."

It seems to me that a more useful way of approaching the problem of the adequacy of a given agency's proposal is to ask two questions: (*a*) Is the technical activity of the agency adequate to provide the service for which it is responsible; and (*b*) is the scientific activity of the Nation adequate to provide the scientists and the institutions of science which, in the vision of farsighted men, will be necessary to meet the needs of the future? The latter might be called the basic research of the agency.

9. What relations exist between the Bureau of Standards and the National Science Foundation concerning basic research at the Bureau? Based on this experience, what voice should the Bureau and other departments and agencies have in identifying fields of basic research for NSF support?

9. Members of the Bureau staff, in general, maintain close professional contacts with their counterparts on the staff at the Foundation. Reports and information are exchanged through the usual scientific and technical channels. Bureau technical personnel frequently serve as referees on grant proposals to the Foundation. Foundation personnel frequently are consulted by Bureau personnel on matters pertaining to research, likely sources of competent assistance, etc. As a general rule, the Bureau programs do not seek funds from the Foundation; exceptions have been the standard data reference system and areas of information technology.

At present, exchange of information in identifying fields of basic research between the foundation and the Bureau has been excellent. No formal voice has seemed necessary from the Bureau point of view. It should be pointed out, however, that the facilities at the new Bureau site should make university-NBS cooperation increasingly attractive. It is likely, therefore, that Foundation grants at universities could be used to advantage in joint university-NBS research, and it would be desirable to develop a joint Bureau-Foundation policy to promote such activities.

9a. What relationships do or should exist between the Foundation and the Institute of Applied Technology concerning application of the results of scientific research and the development of new technologies?

9a. There has been only a limited relationship in the past since IAT interests are largely engineering oriented as contrasted with basic science. Some special relationships are maintained between certain parts of the Institute. The Clearinghouse for Federal Scientific and Technical Information is discussed in the answer to question 13. The Technical Analysis Division has used some of the statistical information on Government-supported R. & D. The Information Technology Division has, from time to time, had special projects funded by NSF.

10. The point has been brought out during the hearings that certain research projects are referred to the National Science Foundation by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency "X," agency "Y," or both. More specifically:

(a) What guidelines or criteria has the Department of Commerce established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the Department's jurisdiction and, therefore, should or should not be supported by Commerce?

(b) If written criteria have been established, please submit a copy thereof to the committee.

10. I have tried in answering the earlier questions to specify what I believe should be the criteria determining whether a given research project should be funded by NSF or by another mission-oriented department. In either case, the determination should be made in the context of the mission requirements of the agency.

Let me give an example. One the great opportunities for improving the prediction of the weather lies in substantial improvement of the observations of the world's atmosphere. Once an agency responsible for work in the atmospheric sciences has made the decision, it can then concentrate on projects that improve the means by which observations are to be made and by which the data are to be collected, and the computing techniques by which the data are to be analyzed. In addition, the agency will have to sponsor research leading toward further understanding the dynamics of the atmosphere. That is necessary in order for the data to be used effectively in building models which closely resemble the actual characteristics of the atmosphere.

Which agency supports that or any other project? The determination should be made on the basis of the project's relationship to the mission of the agency.

(a) The Department of Commerce has not established quantitative criteria for making that determination. We are influenced by the recommendations of the Commerce Technical Advisory Board, by its panels, and by the technical needs of our bureaus. That is the policy of the National Bureau of Standards and of the Environmental Science Services Administration.

Furthermore, the determination of what work should or should not be undertaken by the Department of Commerce's scientific bureaus occurs through a complicated decisionmaking process, which involves each of the bureaus plus the other offices of the Assistant Secretaries, the Bureau of the Budget, other Cabinet departments, etc. These decisions are based on explicit considerations of the respective missions of the various components. To discuss the process further is difficult because it is long and complex. The important point is that it is very workable.

(b) Written criteria are not available.

11. Have Government-wide standards been established for scientific fellowship awards and stipends? If so, who establishes them and what are the standards?

11. There are no established formal standards. In practice, however, most agency awards follow the pattern set by the NSF. Informal coordination is frequent, and so far as Commerce is concerned, quite adequate and satisfactory.

51-204—65—vol. II——28

12. What would you construe as the proper ratio between project grants and institutional support with regard to NSF?

12. In answering question 2 above, I said that I believe there ought to be three different kinds of programs supported by NSF: Support for the scientific work of individuals or teams, support for scientific and educational institutions, a better understanding of our physical, social, economic, and political world.

At present the institutional support portion of the NSF program, as I understand it, ranges in the order of 10 to 15 percent of its support activities. Project grants and fellowship grants constitute the remaining 85 to 90 percent. I believe that, over the next several years, support for institutions and for new and important fields of scientific inquiry should increase to, let's say, 25 to 30 percent of the NSF expenditures. When that level has been reached, I think the NSF should reassess the problem to determine whether that level is adequate.

This matter is one of value judgment. It is very difficult to arrive at quantitative decisions. I am confident, however, that the present ratio between project grants and institutional support is incorrect; that there is inadequate support for institutions and for new fields of scientific inquiry; and that support for both institutions and new fields of inquiry should be increased.

13. You referred to the Harris bill, H.R. 3420, which pertains to regional science information services that the Department of Commerce might provide.

(a) With respect to section 2(a)(2) on "preparing and disseminating technical reports, abstracts, computer tapes, microfilm, reviews, and similar scientific or engineering information, including the establishment of State or regional technical information centers for this purpose"—Is not the Clearinghouse for Federal Scientific and Technical Information in the Institute for Applied Technology, National Bureau of Standards, already providing these services to interested institutions and persons throughout the United States? If not, what is the difference between the services of the Clearinghouse and those mentioned in the bill?

(b) Section 2(a)(3) of the same bill discussed "a reference service to identify sources of engineering and other scientific expertise." Don't the Science Information Exchange and the Library of Congress referral system provide this service? If not, what are the differences among the various information services that are available?

13. The Clearinghouse for Federal Scientific and Technical Information (formerly the Office of Technical Services) collects, announces, and distributes to the public unclassified technical information from the Department of Commerce, the Department of Defense, Atomic Energy Commission, National Aeronautics and Space Administration, and other Federal sources, plus translated foreign technical reports. The Clearinghouse also provides some other services which are not available elsewhere, such as technical literature searching, using the combined facilities of the Clearinghouse, the Library of Congress, and the Departments of Interior and Agriculture. The Clearinghouse

supplies only information, principally documents, generated from Federal programs.

Documents have their place, but some types of information needed by business and industry throughout the country are not found in documents. Such information may not be related to the basic technical programs having to do with space, defense, or atomic energy, either. It may be unsophisticated information.

The State technical services program, recently authorized by the 89th Congress, goes much further than any documentation activity. Under this program, the States are now identifying their principal economic, industrial, and technical problems and developing 5-year plans for the economic and industrial growth of the respective States. Through local leadership, local initiative, local resources, and local participation, the State-chosen agencies will plan and conduct these programs.

Business and industry need information in addition to that printed and otherwise in tangible form. They also need information that is so new that it is available only in the minds of men. The kind of thing which helps businessmen most is seminars, demonstrations, films, computer tapes, and other tools of an active teaching type, and those will be the techniques most heavily used.

The State Technical Services Act also calls for the establishment of a reference service to identify sources of scientific and engineering expertise. What is intended in this reference service, which is barely being organized now, is the identification of private consultants, research companies, non-profit institutes, or university groups that are knowledgeable on a given technical subject. Any company or any citizen will have access to these names. He can then contract directly with the source of expert help.

Such technical assistance as is provided in the bill is not generally available from any other source in the form in which the Department of Commerce plans to provide it. Thus it does not duplicate either the Science Information Exchange or the Library of Congress referral system.

14. What relationships exist between the scientific and technical information activities of the Foundation and the Department of Commerce? Are they adequate?

14. Dr. Burton Adkinson, head of the NSF Office of Science Information, strongly urged formation of the National Standards Reference Data System and has been one of the strong supporters of the program since its inception.

Dr. Adkinson and other members of his staff are kept informed and hence have a good, broad understanding of our methods of operation and other achievements.

Many of the activities supported by the National Science Foundation are of great interest and importance to the operation of the National Standard Reference Data System. In particular, the proposed program with Chemical Abstracts can aid the accomplishment of the objectives of the NSRDS greatly, especially if it is ultimately possible to identify through Chemical Abstracts the papers and the literature which contain data worthy of further examination. This was one of the objectives in the original Chemical Abstracts proposal to the National Science Foundation, which has not yet been funded.

The Clearinghouse has several activities which exemplify the close relationship with NSF:

(*a*) Under Public Law 480, the special foreign currency science information program of the Clearinghouse is supported by NSF to carry out translation contracts with Israel, Poland, and Yugoslavia. Items are translated at the request of eight major Federal agencies, and the Clearinghouse administers the translation, publication, and distribution of these items. The Clearinghouse also makes these items available to the general scientific community.

(*b*) NSF collects and disseminates information on current research and development in the field of documentation. It supports a Clearinghouse activity for the acquisition, announcement, and distribution of reports relating to this specialized field.

(*c*) The Clearinghouse assists in the evaluation of requests for grants received by NSF in the documentation and information fields.

(*d*) Staff members of the Clearinghouse and the Office of Science Information Services at NSF work together on a number of task forces for the Federal Council for Science and Technology's Committee on Scientific and Technical Information (COSATI) in dealing with technical information dissemination problems. The Director of the Institute for Applied Technology is a member of COSATI.

(*e*) Daily working relationships are maintained. For example, the Clearinghouse Director is a member of the Science Information Exchange Advisory Board, which assists the NSF, as supporting agency, and the Smithsonian Institution, as the operating agency, in matters of policy.

15. What is the relationship of the data-gathering activities of the Bureau of the Census to the work of the NSF in collecting and analyzing information about research and development activities? Are any changes or improvements indicated?

15. The chief work of the Statistical Research Division of the Census Bureau is in the manufacturing sector of the economy, and is conducted for and paid for by the National Science Foundation. No analysis is involved, only collection.

In 1962 and 1963 the Division conducted a survey on occupations in industry. This survey was sponsored by three agencies (including NSF), and was paid for mostly by NSF.

Every year the Division conducts a survey for NSF of industry support of research and development for NSF. These relationships are good, and the Census Bureau has no recommendations for improvement.

16. Exactly how do you make use of the Science Information Exchange?

16. At the present time, except for the Clearinghouse, the National Bureau of Standards makes little use of the services of the Science Information Exchange. The Office of Standard Reference Data does maintain contact with the SIE and is familiar with its methods of operation; some of its contractors use the SIE, especially as a means of locating workers in special fields of activity.

The Clearinghouse and the SIE have a close working arrangement whereby computer tapes of the SIE are available for the Clearinghouse to answer its reference requests. Currently, they are jointly engaged in a new announcement program for telling industry what federally supported research and development is in progress in the physical sciences, engineering, and related technological fields. The SIE is supplying the information, from its computer, which the Clearinghouse will incorporate in its regular announcement journal, U.S. Government Research and Development Reports, used by industry as a reference guide. This provides industry a single source reference both to on-going and completed federally supported research and development.

There is daily liaison between the two agencies, and, as mentioned in the answer to question 14, the Clearinghouse Director is a member of the SIE Advisory Board.

From time to time the Environmental Science Services Administration (ESSA) has solicited from Science Information Exchange its entire file of projects bearing, for example, on meteorological problems. While the file was useful, it was found to be somewhat deficient in certain areas, particularly with regard to the in-house projects of some Federal agencies. We plan to continue use of SIE facilities for information on Government research and development relating to ESSA programs.

17. In respect to getting information on available science and technology support from agencies like yours, how does a science teacher from a small undergraduate liberal arts college go about applying for Federal assistance of specific research and educational projects?

(a) Is there a central organization in Washington available to disseminate the names and locations of Federal agencies upon request of these teachers, or must they search for support by coming to Washington themselves?

(b) Do you believe there should be regional centers established to provide this information?

(c) Or perhaps should a Federal Government representative visit individual colleges annually to give current information to science teachers and to identify projects which would be worthy of Federal support?

17. This is a broad field in which the Commerce Department has no specific responsibilities, hence I prefer not to comment.

18. Please supply additional data on the National Standard Reference Data System in regard to such matters as purpose, scope, size, budget, and method of operation.

(a) How is the work "critically evaluated"?

(b) Is the work done in-house by the Bureau of Standards, or is it contracted out? What is the percentage of each?

(c) How are the compilations produced and disseminated?

(d) Is it available to Government, industry, and private individuals?

(e) Is there any cost for the service? How much?

18. Under the Federal policy statement issued by the Federal Council for Science and Technology, which established the National Standard Reference Data System, this system is specifically identified as one of the components of the national scientific and technical information

systems. The NSRDS is concerned with one part of the entire scientific and technical information problem, that of providing to the technical community of the United States critically evaluated quantitative data on the physical and chemical properties of materials and other substances which are structurally insensitive. For management purposes, this has been set aside as a task to be managed separately from other components of the total system. The NSRDS will be aided greatly by the other components which are now being planned, and in turn will feed its output back into the total system for the benefit of all users. There is no overlap of function. The NSRDS carries out both functions of the entire scientific and technical information system which are concerned with the evaluation and compilation of lasting data on the physical and chemical properties.

Purpose of NSRDS: The specific objective of the NSRDS is to insure that the scientific community has maximum access to critically evaluated quantitative data in the physical sciences and engineering. Its products are compilations of data on the physical and chemical behavior of well-defined substances and systems, evaluated by specialists, and disseminated through a variety of mechanisms so that the data are available to all who need them. The NSRDS is envisioned as the total complex of activities of this type undertaken through Federal agencies, with central coordination, planning, and standardization by the National Bureau of Standards.

The system integrates to a single point of responsibility the present data-compiling activities of the National Bureau of Standards, Department of Defense, Atomic Energy Commission, National Aeronautics and Space Administration, the National Science Foundation, and several other Government agencies. In addition to its assigned responsibility for this type of work within the Federal Government, the system offers mechanisms by which private industry and academic institutions can voluntarily cooperate to solve many mutual problems and answer many common needs.

Data compilation projects have been a traditional part of the NBS program in fulfilling its responsibilities to the national measurement system of the United States. In 1963 the Federal Council for Science and Technology requested NBS to assume a direct role in all Government data-compilation projects and established the NSRDS with NBS as the administrator.

Scope

Functions: The assignment to the National Bureau of Standards by the Office of Science and Technology includes the following tasks:

1. Operation of a National Standards Reference Data Center at the National Bureau of Standards.
2. Coordination of standard reference data activities of NBS, DOD, AEC, NASA, NSF, and other governmental agencies, all of which may operate components of the National Standards Reference Data System, if this is mutually decided.
3. Establishment of standards of quality for various products of the NSRDS.
4. Establishment of standards of methodology, including machine processing.

5. Establishment of standards for such other functions as are required to insure the compatability of all units of the NSRDS.

Technical scope: In order to develop a comprehensive plan of operation, it was necessary first to decide which fields of science and technology should be included and then, in those fields, which kinds of data were appropriate for collection and evaluation. These decisions have been made in general terms by focusing attention on physical phenomena only (that is, no biological effects are included) and by defining "standard reference data" to mean critically evaluated quantitative information relating to a property of a definable substance or system.

Specific definition of the scientific scope of operations of the NSRDS is provided by the list of seven technical areas chosen for initial attention. They are:

1. Nuclear properties.
2. Atomic and molecular properties.
3. Solid-state properties.
4. Thermodynamic and transport properties.
5. Chemical kinetics.
6. Colloid and surface properties.
7. Mechanical properties of materials.

Operational activities: For the compilation of standard reference data, four types of activities are considered to be appropriate in the program of the NSRDS:

1. Data collection and evaluation: Scanning the literature to locate relevant data and background information, exercising critical judgment, and compiling the evaluated data in an orderly format.
2. Preparation of critical reviews: Examination of the status of quantitative knowledge in a special aspect of a technical field, including a survey of experimental uncertainties and limitations and theoretical background, and development of new relationships between properties, as may be appropriate.
3. Computation of useful functions: Derived from standard reference data (e.g., thermodynamic functions), of values of theoretical or semiempirical functions used in the interpretation of quantitative experiments, or of estimated values of unmeasured properties of important substances.
4. Experimental measurements: Determination of experimental values of properties needed to fill gaps in tables to extend the range of a parameter over which a property is measured, or to obtain a more precise figure. (Not to support research merely to develop a new or better measurement technique.)

Size

The size of the National Standard Reference Data System should be considered in relation to the magnitude of the task, expressly considering the present compilation effort, including budgets and size of staff, and the benefits to the Federal budget and the general economy.

Magnitude of the task: The nature of basic research in physical science and technology inherently involves, in most cases, making a quantitative measurement of some property of a material or system. The results of these measurements are very seldom an end in them-

selves. The contribute to an understanding of the structure and natural processes of the world in which we live; they form the basis for applied research; and they are needed for engineering and design activities. In principle, the publication of these data in journals and reports makes them available to those scientists and engineers who need them. In practice, however, there are two major difficulties: first, the great physical effort required to survey the literature to discover relevant data, and, second, the intellectual effort of evaluating the worth of the data.

The rapid growth in quantity of data is indicated. For example, Chemical Abstracts published 1 million abstracts during its first 32 years of operation, a second million abstracts in the following 17 years, and a third million in the next 8 years. It is expected that the fourth million will appear in 5 years or less, with the 1963 Chemical Abstracts listing approximately 170,000 abstracts. Current estimates indicate that the total accumulated volume of scientific information of interest to chemists will double by 1975. The National Science Foundation estimates current research projects now cost an average of approximately $40,000. On this basis, the research reported in 1963 by Chemical Abstracts corresponds to approximately $5 billion.

The fraction of the world literature reported by Chemical Abstracts which is attributed to the United States is estimated to be 25.3 percent of the total; the fractions attributed to the Soviet Union, the British Commonwealth, and Japan have been estimated to be 23 percent, 13 percent, and 7.6 percent, respectively. The increase in the number of papers has been reflected also in a corresponding increase in the number of journals in which technical literature is published. The number of technical journals now being published throughout the world is estimated as high as 30,000. The majority of the useful information in any given field of specialty, however, is normally published in a relatively small number of journals, usually less than 100. But even this number is more than the average specialist is prepared to keep up with.

The task set for the National Standard Reference Data System is to insure that all the data of lasting worth in the literature are collected, critically evaluated, and made available to aid the Nation's progress in defense, space technology, nuclear technology, and other branches of technical industry.

Magnitude of present compilation efforts: Underway in the United States are major projects under the sponsorship of the National Bureau of Standards, the Atomic Energy Commission, several agencies of the Department of Defense, and the National Aeronautics and Space Administration, with lesser efforts sponsored by other governmental and nongovernmental agencies. In addition, important programs are underway in other countries and are, of course, taken into account in the development of the U.S. program. The total world effort is estimated to cover 15 to 20 percent of the available reservoir of data in the literature. In special areas, notably nuclear data, the coverage is considerably higher.

Total Government expenditures in the United States for data compilation projects during fiscal year 1965 are estimated to be about $4 million, of which $1.5 million was disbursed through the NBS Office of Standard Reference Data and $2.5 million from other agen-

cies such as DOD, AEC, and NASA. To cover the available data reservoir in the manner recommended by the advisory panels of specialists who have considered the problem, a total budget approximately five times as great as that now available would be required.

At the present time the staff of the NBS–OSRD consists of 13 persons, of whom 6 have strong technical backgrounds. It is estimated that the size of staff required for coordination and standardization activities plus the provision of a variety of services to the U.S. technical community making use of the stored data would be approximately four times as great. This size staff would be needed in 3 to 5 years if the program develops as now planned. Other agencies would be expected to maintain but not to increase the program management staffs now employed on NSRDS projects.

Magnitude of benefits to the Federal budget and the general economy: The ways in which compilations of standard reference data improve effectiveness and increase efficiency are the following:

1. By providing ready access to quantitative data already determined but not now conveniently available to the user;
2. By reducing duplication of effort in laboratory measurement programs;
3. By reducing the time required by technical specialists in locating and evaluating data which are available, or in fruitlessly searching for data which do not yet exist; and
4. By minimizing the errors in decisionmaking and in engineering design caused by use of inaccurate or inadequately evaluated data.

Estimates of such contributions made by a few of the major compilation projects now in existence indicate the benefits to be 50 to 100 times greater than the cost of producing the compilation. This means that the Nation's research and development program may be penalized by as much as 5 percent by the absence of an adequacy of standard reference data. The purpose of the NSRDS is to reduce that penalty.

Method of operation

The role of the NBS in the NSRDS is that of a "systems manager," and has two operational aspects—input and output. Input takes place in each of the seven technical categories listed previously. The planning and implementation of a program in each of these categories is the direct responsibility of a member of the staff of the Office of the NSRDS at the National Bureau of Standards. This responsibility involves the following steps, many of which are taken concurrently over an extended period. Each category is subdivided into areas of smaller scope listing and organizing in a logical fashion the subfields which in the opinion of specialists comprise the broad category. This step constitutes a definition of the field.

The next step in the development of the program is a survey of the operations of existing data compilation and evaluation groups. This survey determines the technical scope covered, the nature of the output, the number and types of staff required, the financial arrangements, plans for the future, and other relevant information. The help of consultants and leading members of the NBS staff is enlisted in these first steps.

When the field is defined, and some knowledge obtained of the existing activities, the program leader in each area works closely with a panel of consultants, each of whom is a specialist in an appropriate field. The participation of outstanding leaders of the technical community of the United States is sought for these panels. Each panelist is asked to contribute throughout the program. The recommendations of these panels are perhaps the most important factor in the operational decisions made in the NSRDS.

The production of systematic compilations of standard reference data is half the basic task of the NSRDS. The other half is to make these compilations most conveniently available to the user, in the technical community, who needs the data. The Office of Standard Reference Data plans to operate a variety of services, consisting of three main components:

1. Maintenance of a complete file of "Standard Reference Data."
2. Operation of an Inquiry Service.
3. Operation of an Editorial and Publications Service.

The data file is to have a complete collection of all compilations of "standard reference data" produced anywhere in the world, organized systematically and stored for rapid retrieval. The Inquiry Service is to (1) supply replies to specific inquiries addressed to the Office of Standard Reference Data, (2) prepare a current awareness journal which shall contain information about the services available from NBS and about newly appearing compilations of current activities undertaken throughout the world, and (3) operate a variety of other specialized services. The Editorial and Publication Service will have the capability of converting the raw product from a data compilation group into finished monograph, IBM cards, looseleaf data sheets, microfiche, or any other convenient form. At the present time these activities are in the early planning stages; they are to be initiated and expanded as rapidly as the availability of funds will allow.

(*a*) *Critical evaluation of data*

The essential step in critical evaluation of data is the exercise of judgment by a specialist in the field of the data. In exercising judgment, the data evaluator may confirm calculations, apply alternative interpretations, appraise purity of substances, compare data obtained from several sources, and seek explanations for discrepancies. In most cases, the specialist will select a particular value as the most reliable available for the property under consideration.

(*b*) *In-house versus contract projects*

At present, less than 20 percent of the total NSRDS compilation activity is carried out at NBS, and it is planned that this fraction will decrease. Of the total funds disbursed directly by the NBS–OSRD, the in-house and contract fractions are roughly equal, but this ratio will change as the out-of-house effort increases.

(*c*) *Production and dissemination of compilations*

In general, NSRDS compilations that are produced as a result of financial support through the NBS Office of Standard Reference Data are published and distributed through the Government Printing Office. In other cases, a variety of mechanisms may be used, since the

primary criterion is ease of access by the ultimate user. Where an existing project has its own well-known distribution mechanism, no additional mechanism will be used. The distribution channels of other Government agencies will be utilized where appropriate. Distribution by a cooperating nonprofit organization is also under consideration. Private publishing houses have expressed interest in cooperating, but their preference for exclusive rights is difficult to reconcile with the "no-copyright" principle of most Government-supported research. Monographs and books are among the suitable forms for standard reference data. Some data will be made available on punch cards, magnetic tapes, looseleaf sheets, and perhaps through teletype and eventually closed circuit television or other devices.

(*d*) *Availability of products and services*

It is planned that all products and services will be available to all members of the technical community, whether employed by Government, industry, or academic institutions.

(*e*) *Costs for the products and services*

Printed products distributed through GPO are priced in accordance with the usual policies. Other products, such as tapes, IBM cards, and data sheets, will be distributed at prices set to recover the cost of reproduction and distribution. Special services provided by the NBS Standard Reference Data Center (such as computation of special functions, extensive file searching, or special tabulation), will be priced in accordance with NBS practice for calibrations and other similar services.

*19 and 20. Public Law 85–510 empowers the National Science Foundation to conduct a national weather modification program. This act further provides that "other agencies of the Government are authorized to loan to the Foundation * * * such property and personnel as may be deemed useful" in carrying out the weather modification program of the Foundation.*

(*a*) *When will this report be available to the committee?*

(*b*) *Does this action indicate that the Weather Bureau would like to establish its own weather modification program?*

(*c*) *Wouldn't this require specific legislative approval?*

(*d*) *If the Weather Bureau does have the capability in this field, what provision has it made, or what provision does it expect to make, for loaning this capability—that is, property and personnel—to NSF as authorized by the above act?*

(*e*) *In your view should not the NSF continue to support research in this area even though statutory responsibility for conducting a national weather modification program itself might be withdrawn?*

(*f*) *Would you comment on the prospects and problems of weather modification in relation to the statutory mission of the Foundation?*

19 and 20. (*a*) This report has been publishe., and a copy is attached. (The report is in the committee file.)

(*b*) ESSA, through the Weather Bureau, already has an active weather modification program. At present, the main thrust of this program is directed toward the modification of severe storms. ESSA is now formulating the future direction of the program—

to determine where it should be broadened and what the general role of ESSA should be in weather modification. This formulation will require extensive discussions with the Executive Office of the President, with other Federal departments and agencies, and with the National Academy of Sciences.

(*c*) ESSA does not require new legislative authority to conduct a broadened program of weather modification research. It has implied authority for such a program under its general statutory mandate to warn the public of weather hazards, to promote the safety and efficiency of air and sea navigation, and to foster agriculture and commerce. Conceivably new legislation might expressly assign special responsibility to ESSA for weather modification.

(*d*) The National Science Foundation has no weather modification research facilities or capabilities of its own, and it does not itself operate programs of research in weather modification. The primary function of the Foundation in the area of weather modification is to provide financial support for research by others, and the Foundation requires only a few personnel to perform this work. The Foundation has not sought to borrow property or personnel from the Weather Bureau to assist it in its activities under Public Law 85–510. ESSA stands ready, of course, to render such assistance.

(*e*) The Department of Commerce believes that the National Science Foundation is an important link between the Federal Government and the scientific community in the area of weather modification (as in other fields of scientific endeavor) and that this link should be maintained. It also feels that it is important that there be no diminution in principle of the role of the Foundation as a supporter of basic scientific research in the United States. For these reasons the Department would favor having the Foundation continue to provide financial support to basic weather modification research.

(*f*) I believe that assignment of the central coordinating responsibility for weather modification to NSF should be reexamined as the program develops.

21. What additional information would be useful for NSF to collect?

21. The first suggestion would be to make a number of revisions in the industrial categories used for structuring the information on research dollars and manpower. It is not possible, for example, to identify research and development of the building industry from the present categories.

It would be of obvious value to have a measure of privately supported research and development as broad as possible in terms of the number and kinds of firms and institutions interviewed.

The present definitions of basic and applied research seem less useful to those interested in the relationship between research and the growth of technology than they do to scientists. Some categorization which attempted to identify research along the following lines would probably be more useful:

1. Studies designed principally to establish statistical relationships which are not a part of the physical sciences, e.g., how many

college students still work in their hometown? What is the migration pattern of Ph. D.'s by age group, by field, etc.?

2. Studies which are intended to gather information of value to those doing research, but not directly related to research itself, e.g., which universities are conducting research programs on hydrology? What current research projects are being done which should be of interest to the American Society of Civil Engineers?

It would be very desirable if the Foundation also could identify:

1. Research programs designed to advance man's understanding of his physical world for intellectual reasons alone. (Most of this would be in universities and Government labs. So-called industry "basic research" would seldom qualify.)

2. Research done to advance man's knowledge broadly in the medical sciences, excluding drug development if possible.

3. Research done to advance man's knowledge of his social, psychological, or economic world. The extent and nature of most of the work in this area is clearly separable from research in the physical and medical sciences.

4. Research done to find ways of applying scientific or basic engineering knowledge to problems which will not result in manufacturable products, e.g., water desalinization principles, basic fire research, thermoelectric principles.

5. Development of new products as a result of technological advances. This needs to be separated to the extent possible from normal model changes studied to induce consumer demand.

6. Testing of quality and reliability to the extent possible.

22. Do you believe that some applied projects that are in the national interest fail to gain support because each agency gives such a project a low priority, although the aggregate of these multiple requirements might warrant a higher priority?

22. I believe that there are several such fields. Oceanography is certainly an outstanding example. As I testified before the Oceanography Subcommittee of the House Merchant Marine and Fisheries Committee on August 4: "Oceanography is not a unitary concept. Speaking very generally, it embraces two broad areas—the description and prediction of oceanic conditions and the exploitation and utilization of ocean resources. I believe that each of these areas would be enhanced if a single agency were to provide a focus for the activities in that area—and to provide strong leadership for these activities." The remedy may not require centralization in one agency, but it might lie in giving explicit authority to one or more Government agencies to take the lead.

Response by Dr. Herman Pollack, Acting Director, International Scientific and Technological Affairs, Department of State, to Questions of the Subcommittee on Science, Research, and Development

---

1. Do you consider science as a tool of international diplomacy? In this connection:

(a) What contributions do international scientific ventures make to our foreign policy?

(b) What have been the effects on foreign relations of scientific research sponsored abroad by the National Science Foundation, the Office of Air Research, and the National Institutes of Health?

1. The intimate connection between the advancement of science and our national welfare makes science an important factor in the development of our foreign policy. It provides in a unique fashion the means for furthering the friendly spirit of international cooperation by broadening the areas of understanding between the United States and foreign countries. Associations generated through common interests in science and technology have added a new dimension to the conduct of foreign affairs. Subjects of such cooperative ventures are weather satellites, desalination technology, medical science, and food preservation. Cooperation in these areas also develop market opportunities for the use of U.S. technical equipment and the international prestige of the United States is enhanced.

(a) International scientific ventures usually relate to undertakings which are beyond the capacity of any single country or which would be facilitated by a multilateral approach. This very pattern of working together with other countries toward mutual goals is a cornerstone of our foreign policy.

(b) Scientific research sponsored abroad by the National Science Foundation, the National Institutes of Health, the Office of Air Research, and indeed also by other branches of the Department of Defense, by the Department of Agriculture, the AEC and other Government and private sources has had a generally beneficial effect upon U.S. foreign relations. It has tended to promote contacts between U.S. technical people and associated political and administrative colleagues on the one hand and their counterparts abroad on the other. The latter often have positions of political as well as scientific and economic significance in their several countries.

The continuing research process in international association accents the mutuality of scientific and technical problems, interests and goals and their extension across international boundaries, building interdependence between the United States and foreign countries that contributes significantly to understanding and to other U.S. foreign policy objectives. This holds true not only for AID-type research sponsorship in certain developing nations but also for U.S.-sponsored

research in technically advanced countries in which we support research primarily in order to obtain results not as easily procurable domestically.

Aside from the intrinsic knowledge gained, U.S.-supported research has tended to enlist the sympathy and interest of foreign scientific communities in the goals of our technical agencies. It has assisted the indigenous research programs of foreign countries, sometimes very significantly as in Israel. Although usually only a small fraction of the total research-support in a foreign country, U.S. funding has often spurred the local governments to increase the amount and flexibility of their own research investments.

Recent cutbacks in U.S. support of research abroad have usually been met both with a measure of regret and with expressions of appreciation and understanding, illustrating the point that these programs have benefited our relations with other countries. Where conditions of research have been difficult, as in NIH work in Ghana, they have stemmed from extraneous political problems. It is evident that U.S. Government research abroad is most successfully conducted, in a diplomatic sense, when local government authorities have full cognizance of the operations in question. When that point is observed, there is no doubt that science generally and U.S.-sponsored research abroad in particular are effective tools in international diplomacy.

2. Following up your testimony of July 20, how does the State Department participate in international scientific ventures of the Foundation? What initiative and control is appropriate to the State Department and for the Foundation in new international ventures in scientific research?

2. The National Science Foundation provides the administrative and backstopping support to U.S. participation in the scientific activities of the OECD and to certain aspects of the NATO scientific program. In addition, it provides comparable services to the United States-Japanese cooperative science program. These activities have been undertaken by the NSF at the behest of the Department of State and are carried on in close cooperation with the Department of State and under its general policy guidance. On programs such as those of the NSF related to the International Year of the Quiet Sun (IQSY), the Indian Ocean Expedition and the Antarctic, the Department of State facilitates the establishment of necessary relations with other participating countries, provides guidance on policy implications and impact of these ventures and, as appropriate, carries on negotiations for other country participation.

The principal control appropriate to the State Department on such ventures is that of insuring that such activities are consistent with U.S. foreign policy objectives and advance the international relations and interests of the United States. Generally speaking, the initiative on international scientific ventures should have its origin in the substantive requirements posed by the subject of the venture. However, there will be increasing opportunities in which the course of wisdom will suggest the use of scientific cooperation and concomitant scientific relationships specifically for the purpose of improving our foreign relations and for obtaining objectives of our foreign policy. We believe that such initiatives should not be shied away from provided there is a sound scientific justification for the proposal itself. In a

related vein, President Johnson stated on August 5, 1965, following a report made to him on a joint project with Korea:

"I believe the language of science offers us new and still largely unstaffed opportunities for international understanding and cooperation. I am hopeful that we may develop an increasing number of joint programs in which the talents of our science and those of other countries can be united in constructive endeavors."

3. Are any scientific research programs overseas supported by the Agency for International Development? Please identify the scope, cost, and foreign countries involved. Does AID coordinate its scientific research support with NSF and with your office?

3. (The following response was supplied by the Office of Research and Analysis, AID.)

AID is supporting scientific research in the less developed countries in a number of different ways:

(*a*) By contracts with non-U.S. institutions for specific research projects. At present, there is one such contract in the area of a research program per se. There are in addition a number of short-term contracts in the nature of surveys, feasibility studies, etc., in connection with specific operational activities. The major research contract is with the International Institute for Educational Planning, a UNESCO affiliate based in Paris.

The purpose of this research is to determine the feasibility of applying the new technologies of education to the problems of the developing countries. The use of such instruments as television, radio, films, recordings, and programed instruction is being assessed in terms of such factors as cost, educational effectiveness, and local conditions. A result of this work, at its completion in December 1966, will be a publication containing guidelines for assessing the feasibility of introducing and utilizing new educational media in developing countries.

Work on this study will go on through the analysis of educational activities in approximately 20 developing countries; since work began only in June of this year, the process of making final decisions on which countries these will be is still in progress.

Chief investigator of this project is Dr. Wilbur Schramm, of Stanford University. An obligation of $190,000 has been made by AID for this study.

(*b*) By contracts with U.S. institutions for research projects in the developing nations. AID carries on a broad program of research on problems of the developing nations, conducted through U.S. universities, nonprofit institutions, and Government agencies. During fiscal year 1965, AID's Office of Research and Analysis obligated $11.1 million for research activity in the fields of agriculture, public health, education, social systems, systems analysis, and operations analysis. Work on the 51 contracts under this program is going on in dozens of the developing nations, in close cooperation with local academic and governmental institutions. Attachment A contains summaries of these contracts.

(*c*) Through support in developing the research capabilities of foreign institutions. A list of major activities of this type is presented in attachment B. (It should be observed that in most cases research is only one function of these institutions.)

AID coordinates its research with NSF, the State Department, and other Government agencies. AID submits an annual report to NSF on its research program. The Office of Research and Analysis receives all NSF research reports, and transmits to NSF all reports emanating from its own activities. The Director of the National Science Foundation is invited to all meetings of AID's Research Advisory Committee, a panel of 16 eminent scientists which approves every project in AID's central research program. And finally, continuing formal and informal coordination goes on between NSF and AID research officers in the particular disciplines.

Coordination with the Department of State is also close. Since 1962, the Agency has maintained an agreement with the External Research Staff of the Department of State, under which that staff, which is highly experienced in this field, provides the Agency with information services covering other research efforts, particularly with special bibliographic searches to detect potential duplication or overlapping research. Further, AID joined the State Department and other agencies a year ago in forming the interagency Foreign Area Research Coordination Group (FAR). FAR was organized with the specific purpose of improving coordination of Government-sponsored research on foreign areas and international affairs. Representatives of the Agency have played an active role in the work of this group. Finally, AID projects will be screened under the procedures now being established by the Foreign Affairs Research Council of the Department of State.

(A representative of AID's Office of Research and Analysis attends weekly staff meetings held in the International Scientific and Technological Affairs Office. The purpose of such attendance is to coordinate the interests of both Offices in the field of international scientific affairs.)

4. What financial and administrative devices have been used in leading scientific countries to support basic research? How do these compare with devices used by the Foundation?

4. In France the Ministry of National Education is responsible for work in universities and in those other institutions mainly concerned with free exploratory research. This includes the scientific laboratories of the 19 universities and the higher scientific establishments, such as the College de France, Ecole Normale Superieure, Musee Nationale d'Histoire Naturelle, Observatoire de Paris, Conversatoire Nationale des Arts et Metiers, Ecole Pratique des Hautes Etudes, Centre Nationale de la Recherche Scientifique (CNRS). The CNRS which is "the main instrument of systematic fundamental research" has a large number of laboratories of its own (10 for physics, 8 for chemistry, 13 for biology, etc.), helps to finance the university laboratories, and acts as the "national training ground for research workers." In 1964 it had 4,500 research workers and 6,300 technicians. About 20 percent of its research workers and half its technicians were employed in CNRS laboratories, and the others in the university laboratories. These 4,500 scientists comprised over a quarter of those employed in the public sector, and an eighth of the total in France.

It is worth noting that fundamental research has fared well in France over the last several years, even as other Government R. & D.

expenditures increased. In 1959, approximately 23 percent of the total R. & D. expenditures of 1,750 million francs [1] was spent on basic research; and in 1962, with the total at over 4,000 million francs, the percent for basic research actually increased slightly.

In 1959 special committees reporting directly to the Prime Minister were set up to select certain "concerted activities" (actions concertees) of special scientific interest and of overriding importance to the community. These were funded by a special fund set up in 1961—the Fund for the Development of Scientific and Technical Research (FDRST)—totaling about 50 million francs per year. The funds were used to place research contracts in the best qualified laboratories with some 50 percent of the cost borne by the laboratory itself. Typical concerted activities are: Energy conversion, exploitation of the seas, molecular biology, cancer and leukemia, functions and diseases of the brain, applications of genetics, animal and human nutrition, population analysis, economics and development problems. In 1963 several more fields were added—more technical in nature—e.g., electronics, automation, macromolecular chemistry, etc.

Thus France is characterized, in gross analysis, by significant Federal support for basic research, in the universities and in the Government's own laboratories. Furthermore, there is Central Government selection of priority fields of study, which receive special consideration in allocation of funds.

Germany

In Germany also, most basic research is carried out in the universities, and in the Max Planck Institutes. Certain regional academies of science, and some supraregional institutions also contribute to the total. Financing comes from the Federal Government, and, significantly, from the Länder, or States, and from industry. The chief avenues for financing are the German Research Association (Deutsche Forschungsgemeinschaft) (DFG) and the Max Planck Gesellschaft (MPG). The former has the legal status of a private association, but secures its financial resources from the Federal Government (44 percent), the Länder (44 percent) and the private sector through the Stifterverband für die Deutsche Wissenschaft (12 percent). The current budget of the DFG 1965 is DM133 million.[2] The contribution of the Federal Government to the DFG is a significant part of the Federal budget for the support of general science. In fiscal year 1965, of DM452 million total, DM300 million went directly to the universities; DM60 million to the DFG; DM72 million to the MPG; DM20 million to other.

The Länder have supported the DFG under the terms of the Königstein agreement, a voluntary pact agreed to in 1949, under which the Länder agreed to support certain scientific institutions which were recognized as having more than regional significance. Besides the DFG, the Länder give support under this agreement to the MPG and to some 30-odd major scientific institutions through Germany (such as museums, astronomical observatories, technical libraries, etc.). In 1964 a new agreement was entered into between the Länder and the Federal Government in which each gives 50 percent of the public funds

[1] One franc equals $0.204.
[2] One DM equals $0.25.

made available to the DFG and the MPG. The Stifterverband (Sponsors' Association for the Advancement of Science) collects funds from trade associations and individual firms, and allocates these to the DFG, the MPG, and to limited other centers. Over the years of its existence from 1949, it has collected well over DM200 million for the advancement of science. Some 70 percent of its funds go to the DFG.

The DFG disburses its funds to the universities in a manner similar to the NSF grant system. Proposals from individual scientists are received, judged by consultants, and approved by the main committee which is composed of 15 scientific members, 12 appointees of the Federal and Länder Governments, and 2 appointees of the Stifterverband. The DFG does not engage in actual research, and maintains no research institutes of its own. It gives support, limited in time and amount, to specific research projects.

The main governing body of the DFG, the senate, consists of 33 leading scientists. It proposes, from time to time, "priority programs," wherein distinguished scientists are asked to participate—i.e., research proposals are specifically solicited. The research proposals are considered as a group, and the program approved or disapproved by the main committee. Some 50 priority programs are in existence at any given time, with support of the order of half a million DM per program. Typical subjects are: soil physics, geochemistry, acoustics, chemical thermodynamics, rheumatism research, botanical photobiology.

The MPG, contrary to the DFG, exists solely to maintain research institutes of its own. The original aim was the establishment of research institutes in which eminent scientists would be free from all teaching responsibilities and could devote themselves entirely to research. Today many of the institutes are linked more or less formally to nearby universities, but the emphasis on pure research remains. The 46 institutes and research centers employ over 3,000 persons, including close to 1,000 scientists. In almost every case the institute director, who is selected for life, is given complete authority in determining the direction of research and controlling the funds of his institute. The work of such institutes is often outstanding, because outstanding men are chosen to direct them, but the coverage of science is by no means complete. The MPG is funded by the Federal Government and the Länder (under the Königstein agreement), the Stifterverband and direct grants, and some of its own receipts. In 1965 the MPG has about DM140 million at its disposal, about 75 percent coming from public funds.

In summary, the basic research in Germany is carried out largely in its 30-odd institutions of higher learning (universities, technical high schools), supported largely by the Länder and to some extent directly by the Federal Government. The DFG subsidizes research projects not financed, or only inadequately financed, by the institutional budgets. In addition, close to 50 Max Planck Institutes produce high-quality work in specific fields. These institutes are likewise largely supported by the Government, but a significant fraction of support comes from individuals and private firms through the Stifterverband. The DFG likewise supports "priority programs," comparable to the "actions concertees" of the French. There seems to be no U.S. counterpart to these devices.

England

The most important site of fundamental research in the United Kingdom remains the universities, and support of their expenditures on scientific research (estimated at about £35 million[3] in 1962–63) comes almost entirely from the Central Government. The most important source is the University Grants Committee (UGC). The Committee advises the Chancellor of the Exchequer of the financial needs of the universities on a quinquennial basis, assessing their requirements on the basis of plans and proposals put forth by the universities themselves and adjusted in the light of national needs and likely available resources. From the funds provided by the Government the UGC allocates block grants to the universities for each of the 5 years. Decisions on the balance between teaching and research, and between various types of research, are made within the universities themselves. In the 1962–63 period, the UGC grants totaled £24 million.

The universities receive further support from the Ministry of Science and Education, in the form of grants from the Ministry's research councils, now numbering four: The Medical Research Council, Agricultural Research Council, Science Research Council, and National Environment Research Council. In the 1962–63 period (when the latter two research councils did not exist but with the now defunct Department of Scientific and Industrial Research in existence), some £6 million was made available from these sources, including £2 million in the form of postgraduate fellowships, and £4 million in grants for research on specific projects. The other channels for support of research in the universities are various Government departments, again supporting specific projects, the Royal Society, industry, and the independent foundations.

Research Councils of the Ministry of Science and Education also support institutes of their own, such as the radio research station, the royal observatories, the geological survey and museum and the like, which also carry out significant fundamental research, but not to the same extent as the CNRS in France or the Max Planck Institutes in Germany. Thus the United Kingdom is characterized by concentration of basic research in its universities, and by Government support for this research both by general grants through the UGC and by "earmarked" grants for directed projects from the research councils.

It is apparent that the National Science Foundation's support of basic research largely through the funding of unsolicited research proposals, is mirrored in other countries, as in the activities of the Forschungsgemeinschaft in Germany. Devices used in other countries which are either absent in the NSF programs, or present to a very small extent, are: the support of university departments as a whole, as with the UGC system in the United Kingdom; the establishment of Government laboratories primarily devoted to basic research, as in Germany's Max Planck Institutes or France's CNRS laboratories; the selection, by the Government, of certain fields of science for priority funding, as in France's "actions concertees" and Germany's "Schwerpunktprogramme."

[3] One pound equals $2.80.

5. During our hearings with the Office of Education, it was stated that AID is funding a study in satellite education or educational TV utilizing satellites.

(a) Can you describe these projects, identify the countries involved and the amount funded?

(b) Does AID support scientific educational projects generally, as distinguished from research projects?

(c) Please summarize the international scientific curriculum adaptation programs funded by AID, including the countries, subjects, and cost. Does AID coordinate these programs with NSF?

5. (The following response was supplied by the Office of Research and Analysis, AID.)

(*a*) AID is not now funding a study on educational TV utilizing satellites, although it has for some time had an active interest in the subject.

(*b*) and (*c*) AID is supporting two major efforts at developing the materials for instruction in science and mathematics in the developing countries. Both are in Africa.

The underlying aim of both programs is to provide the skills necessary for analytic thinking and invention. Results thus far indicate that success in attaining this goal is being achieved.

The first is a program designed to develop new mathematics curriculums for English-speaking African students, through development of textbooks, workbooks, and teachers' guides in the "new mathematics." The materials, which are written primarily by Africans, using examples meaningful to Africans, are designed to develop a new, problem-solving approach to mathematics; $2 million has been obligated for this effort since 1962. At present, over 400 classes in Kenya, Ethiopia, Tanzania, Zambia, Uganda, Sierra Leone, Liberia, Ghana, and Nigeria are using the texts on an experimental basis.

A similar, more recently initiated project, begun in 1965, is in science. The purpose is to develop, for English-speaking African countries, an elementary school science curriculum that will emphasize scientific thinking, as opposed to rote learning, and would teach certain functional aspects of daily living such as sanitation, health, and nutrition. The countries to be involved include all those in the mathematics program plus Malawi, Sudan, and Somali. A total of $485,000 has thus far been obligated.

AID has worked in close coordination with the Division of Course Content Improvement of the National Science Foundation in conducting these curriculum adaptation programs. Dr. Charles Witmer, Director of that Division, sits on the board of project overseers for the programs. In addition, NSF publishes reports of these programs and evaluates the textbooks that are produced.

6. What degree of national responsibility do you consider it desirable for the Foundation to assume for international scientific ventures, in comparison with mission-oriented departments and agencies?

6. It is suggested that the National Science Foundation or some other centrally located executive agency should have the flexibility which would permit it to assume responsibility for worthwhile international scientific activities or cooperative arrangements which find no convenient bureaucratic base in the U.S. Government. This would

be especially useful when there would be a high return to our international relations from the scientific venture.

7. Would you explain the respective roles of the State Department and NSF in selecting foreign students for advanced training in the United States?

7. It is understood that the National Science Foundation does not support foreign students for advanced training in the United States. The Department of State, under its cultural affairs program, does provide scholarships for a limited number of foreign students under the Fulbright-Hayes Act. The nomination of these students is usually handled by binational committees established with certain foreign countries. The final selection of the students for scholarship awards is done by the Board of Foreign Scholarships which is advisory to the Department of State.

8. In what ways and for what purposes does information flow between State Department scientific attachés and NSF?

8. As part of our effort to keep the Department's scientific attachés as well informed as possible about trends and developments in American science, we have arranged for them to receive regularly items such as press releases, annual reports, and special studies produced by several technical agencies of the Government. In this context they routinely receive such materials from the National Science Foundation.

Many of the NSF publications, such as its Research and Development Surveys, its studies on scientific manpower and its annual tabulation of research and development expenditures, are of great interest to foreign government representatives. Our scientific attachés are often the recipients of foreign requests for these studies, or call specific, pertinent items to the attention of their foreign colleagues, and the Foundation has been extremely cooperative in making additional copies available for such presentation purposes. This obviously paves the way for a quid pro quo.

Almost without exception substantive reporting from our scientific attachés is forwarded in the form of State Department airgrams. By an admirable system of subject classification, almost all airgrams of general interest are routinely reproduced and circulated to various interested Government agencies, including the National Science Foundation. That the NSF makes use of these reports in its own appraisal of foreign science programs, in learning of new developments in science education and support abroad, and in evaluating research proposals is evident from the frequent requests made for additional information on specific items, or from comment and appraisal. If the NSF seeks information on a specific subject, the Department will prepare or transmit appropriate requests to the embassies.

9. Exactly how do you make use of the Science Information Exchange?

9. Our use of the Science Information Exchange is almost entirely limited to obtaining information on the current support, from U.S. sources, of scientific research projects in given foreign lands. About two times per year we ask SIE to give us a complete tabulation of U.S.-supported research projects in foreign countries. We are working with the SIE and with other agencies to improve their ability to furnish such a comprehensive picture; e.g., we have encouraged AID to make available to SIE full information on its assistance projects in-

volving science and technology. The alternative is an agency-by-agency count of oversea projects, which is time consuming, liable to inaccuracies, and likely to be incorrect by the time it is completed. More rarely, we have asked SIE for a subject matter breakdown; e.g., a recent request dealt with the total U.S. Government support of reseach on terrestrial uses of solar energy, when such was of particular interest in consideration of a foreign project.

10. Scientific talent in our Government has been concentrated in a few departments and agencies of the executive branch. Do you believe that the scientific disciplines, including engineering and mathematics, should be better represented in:

(*a*) *Our Foreign Service officers overseas?*
(*b*) *The diplomatic corps in Washington?*
(*c*) *Our legislative bodies and elective public offices?*

10. (*a*) The Department of State does believe that the scientific disciplines should be adequately represented in both our Embassies abroad and in the Department in Washington. At the present time the Department of State has appointed scientific attachés to 16 key Embassies abroad. These are individuals with broad scientific qualifications and experience. In addition the Department of State as a matter of policy is encouraging individuals educated in the sciences to apply for appointment as regular Foreign Service officers.

(*b*) and (*c*) The Department of State believes it would be inappropriate and impolitic to comment upon the staffing of the foreign diplomatic missions in Washington. This would also hold true in relation to members of our legislative bodies and elective public offices.

11. Since one principal program of the Foundation is the fostering of new centers of scientific excellence throughout this country, it would be interesting to know how it compares in scope and purpose with the establishment by the West German Government of 40 Max Planck Institutes in that country.

11. The new centers of scientific excellence being fostered by the National Science Foundation and the Max Planck Institutes in Germany were both designed to fashion institutions of outstanding scientific competence. The differences between the programs, however, are more significant than the similarities.

The NSF program is more broadly based than the German one. The 46 separate Max Planck Institutes support isolated disciplines ranging from ionospheric physics to the history of art; from agricultural technology to documentation; from civil law to tissue culture; from theology to silicosis. Each institute is virtually independent, with its own facilities, director, budget, and program. The level of performance in virtually every instance is outstanding, but there is little cooperation or interplay among the individual institutes, with universities or with other research organizations. As a result, interdisciplinary research is sharply restricted and cross fertilization is stifled. Scientific areas not included within one of the institutes suffer from relative neglect, so that there is a series of sharp, high peaks of scientific excellence, but also valleys of mediocrity or inactivity. This shortcoming has been recognized by many German scientists and efforts are underway to modify the level of scientific excellence in a number of allied fields within the same institution. It may support

half a dozen or more departments within a given university so that performance within a broad area of science is raised.

Another difference between the two programs is inherent in their locale. The NSF program is attempting to assist additional universities in attaining scientific excellence. This implies not only the development of superior research capacity but also more effective teaching and training of students.

The Max Planck Institutes stem directly from the Kaiser-Wilhelm Society which was founded in 1911 on a diametrically opposite philosophy. They were established to free outstanding scientists from the "distractions" and "wastefulness" of teaching. Staff members have no teaching responsibilities. They are free to concentrate full time on research. Training of the next generation of scientists is left to the universities. Some German scientists have associated themselves with universities and have voluntarily assumed teaching commitments, but these are still in the minority.

A somewhat related point illustrates still another difference in the two programs. The NSF program attempts to strengthen a department or a division or a group of related divisions. Although a number of professors or senior scientists may be involved, the objective is to strengthen the competence to perform significant research or teaching. Support is not contingent upon the presence of any single individual.

The Max Planck Institutes on the other hand, still operate largely on the "one institute, one professor" basis. An outstanding scientist is chosen and the institute built around him. He operates the institute as a scientific fiefdom with virtual autocratic control on personnel, budget, research programs, and so forth. If he dies or retires or leaves, the character of the institute changes to meet the new director's interest. There is little continuity of program from one director to the next.

The effectiveness of the institute is dependent almost exclusively upon the stature of the director. That it has generally been outstanding is reflected in the catalog of German scientists who have won the Nobel Prize—17 of whom have worked in Max Planck Institutes. The present necessity for scientific teams, however, has diminished the effectiveness of the autocratic scientific giant. Gradually, the traditional pattern in the Max Planck Institutes is changing.

To summarize, the purpose of both programs is similar but the operating philosophies are markedly different. The NSF program seems to offer a broader scope. The Max Planck Institutes have a brilliant history of success but are gradually changing their format.

12. We understand the British Ministry of Education and Science presently is studying the best way to locate new universities and to assign R. & D. funds to them. How closely is the State Department following these studies? Is NSF involved? What information is available, particularly about regional factors in the choice of location?

12. The Department of State is following closely the reorganization of the United Kingdom Government with respect to the development of science and technology.

The present Government sees a very direct relationship between higher education and technical and scientific development. The choice of location for new universities was discussed by Labor Party candidates during the 1964 campaign with emphasis on their intention to

place new universities and technological institutes in areas requiring economic stimulation. As of July 1965 the Ministry of Education and Science was involved in a study of where to locate such institutions and of ways to assign R. & D. funds to them; however, we have no information to date that the study has been completed.

It might also be noted that the Government has announced its intention to create a new institution for scientific and technological education and research in the economically depressed northeast region.

13. The point has been brought out during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency "X," agency "Y," or both. More specifically:

(a) What guidelines or criteria has the Department of State established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the Department's jurisdiction and, therefore, should, or should not, be supported by the Department?

(b) If written criteria have been established by State, please submit a copy thereof to the committee.

13. The only research supported by the State Department is through its external research program of the Bureau of Intelligence and Research. This is a small program, totaling slightly over $100,000 per year. Contracts are concluded with individual scholars or with institutions when a need arises for special information on a foreign area. In view of the small size of the program, and of the fact that the Bureau first identifies a need and then seeks a qualified contractor, it has not been found feasible to establish descriptive guidelines or criteria. A description of the contract program, including a list of typical studies undertaken, follows (attachment C):

DEPARTMENT OF STATE, BUREAU OF INTELLIGENCE AND RESEARCH, EXTERNAL RESEARCH STAFF

POLICY RESEARCH STUDIES PROGRAM, 1962–64

Fiscal year 1962	$125,000
Fiscal year 1963	143,000
Fiscal year 1964	[1] 83,400

[1] Present departmental allocation.

The Bureau of Intelligence and Research was assigned in 1961 the responsibility for starting a program of contract research for policy-oriented studies. The policy research studies program (PRS) enlists the services of social scientists and other experts throughout the country to undertake studies which for lack of time or of highly specialized talent cannot be carried on within the Department. The program's funds also pay for consultants. Many internal studies and reports have benefited greatly from discussions with these outside experts.

When the need arises for special information on a foreign area, the external research staff first insures that the subject has not already been investigated by an individual scholar, a private institution or another agency of the Government. The staff then selects the most qualified scholar in the field and prepares a contract for a study or arranges for consultation.

In some of the long-range studies an outside expert is teamed with an analyst from within the Bureau of Intelligence and Research. For all PRS studies, the external research staff arranges for a project officer from within the Department to monitor the study to insure full utilization of information available in State and to assist the researcher in making the study immediately useful and relevant to the Department.

Most of the contracts have been made with individual scholars rather than with institutions. This approach has made it possible to choose the best available scholars and to avoid the overhead costs that must be included in contracts with institutions.

An unclassified list of studies undertaken since the program began is as follows:

Unclassified Listing of Policy Research Studies, 1962 Through October 1963
(Includes both completed and "in progress" studies)

1. "Communist Internal Warfare and the Security of the Underdeveloped States"—A study of the Communists' increasing use of guerrilla warfare and its political and foreign policy implications. (Fred Greene, Williams College, chief researcher.)
2. "Berlin Policy Paper"—An analysis of the attitudes of our allies toward various political-strategic choices open to Western powers in the Berlin issue. (Arnold Wolfers, Washington Center for Foreign Policy Research, Johns Hopkins University.)
3. "China Study"—An analysis of the adverse effects to U.S. interests if the Chinese Communists should gain entry into the United Nations. (Charles Burton Marshall, Washington Center for Foreign Policy Research, Johns Hopkins University.)
4. "Political Deterrence"—A study of the extent to which political factors might be used to supplement military factors in deterring the Communist bloc from resorting to military aggression in certain vulnerable areas. (Warner Shilling, Columbia University.)
5. "Study of Latin American Political Parties"—A study of the radical parties and the minor leftwing parties and their relationship to the Communists in a Latin American country where the Communists are putting special emphasis on indirect tactics. (Robert A. Potash, University of Massachusetts.)
6. "Demographic and Health Conditions in Communist China"—A study of the population and health conditions in Communist China and their effect on economic, political, and military estimates for that country. (Christopher Tietze, National Committee on Maternal Health.)
7. "Regional Problems in Southeast Asia"—A study oriented toward illuminating some of the major problems common to the countries of this region. (Institute for Defense Analyses, Bernard K. Gordon.)
8. "European Political Integration"—An investigation of Western European attitudes toward the political integration of Europe. (Arnold Wolfers, Washington Center for Foreign Policy Research, Johns Hopkins University.)
9. "Chinese Communist Leadership Study"—A series of studies investigating the structure of Chinese Communist leadership with emphasis on the "second generation" now rising to power. (Donald W. Klein, Asia Foundation; John W. Lewis, Cornell University; John M. H. Lindbeck, Harvard University; Ralph L. Powell, American University—Chief researchers.)
10. "Soviet View of Africa"—An analysis of Soviet writings to determine the current image of Africa, the relationship between Soviet theory and practice concerning Africa, and the degree to which Africans are susceptible to Soviet influence. (John R. Crutcher, University of Notre Dame.)
11. "Political Development"—A study of the political development of a Far Eastern country vulnerable to Communist aggression. Designed to discover ways of strengthening the government against Communist subversion. (Johns Hopkins University—Thomas R. McHale, chief researcher.)
12. "Political Development"—A study similar to that described above on a Latin American country that is particularly vulnerable to Communist subversion. (Johns Hopkins University—Philip Taylor, chief researcher.)
13. "Chinese Communist Power Position Study"—A study of the long-range political problems arising from the shifting power relationships between the Communist Chinese and other Asian nations. (Robert E. Ward, University of Michigan, chief researcher.)
14. "Africa—The Upcoming 'Second' and 'Third' Generation Leadership Groups"—Several studies on the political views and attitudes of the newly emerging African leadership groups. (Douglas Ashford, Johns Hopkins University; William J. Foltz, Yale University; Aristide R. Zolberg, Uni-

versity of Wisconsin; James S. Coleman, University of California at Los Angeles; Donald N. Levine, University of Chicago.)

15. "Sovereign Immunity—Extent of Its Application and Possible Limitations"—A report on the developments in the law of sovereign immunity since 1949. (Joseph M. Sweeney, New York University.)
16. "Chinese Communist Borderlands"—A study of the minority groups in south China and their relationships with the Communist regime and the neighboring countries. (A. Sabin Chase, retired Foreign Service officer.)
17. "North Korean Political Maneuvers"—Studies of the political, psychological, and economic motivations of the North Korean leaders and the interplay of traditional Korean and Communist behavioral patterns and influences. (Evelyn B. McCune, University of California.)
18. "Voting in the United Nations General Assembly"—A detailed study of patterns of voting in the United Nations which indicates the groupings and changes in the voting record over time. (David W. Wainhouse, Washington Center for Foreign Policy Research, Johns Hopkins University, chief researcher.)
19. "A Stabilization and Development Program for Certain Countries Under Communist Threat"—An investigation to determine criteria for effective economic action to support the stability of a southeast Asian country. It pays particular attention to the reduction of any unfavorable impact of possible measures taken by the United States. (Patricia Barnett, INR Consultant in southeast Asian affairs.)
20. "Working Conditions in Africa"—The trends and their implications of African working conditions are studied in an effort to predetermine and therefore prevent Communist exploitation of backward areas. (Elliot J. Berg, Harvard University, and Walter Drew, INR/RAF, chief researchers.)
21. "Potentialities of Regional Organization as a Bulwark Against Communism in Certain Underdeveloped Areas"—A study on the feasibility of encouraging regional organizations as a bulwark against communism in several underdeveloped countries under threat. (Karl Schmitt, University of Texas, chief researcher.)
22. "The Implications of International Monopolistic Practices for U.S. Foreign Economic Policy"—International attitudes and trends toward monopoly industry are assessed and the future role of U.S. industry abroad under such conditions considered. (Corwin Edwards, University of Oregon, chief researcher.)
23. "Attitudes Toward the Sino-Soviet Dispute"—A study of the evolving attitudes of an east Asian country toward the Sino-Soviet dispute. (John C. Donnell, Dartmouth College.)
24. "Politics and Political Parties in the Middle East"—A series of studies which will examine various aspects of Middle Eastern political dynamics as they affect U.S. foreign policy. (Dankwart A. Rustow, Columbia University, and Philip Stoddard, Middle East Institute, chief researchers.)
25. "The Problems of Maintaining National Unity"—This study of a major African nation focuses on the ways and means of strengthening the effectiveness of the government in order to encourage the growth of a sense of national unity. (Merwin Crawford Young, Harvard University and Edward Streator, INR/RAF.)
26. "Political Systems Study"—This study of political organization in a southeast Asian country is planned to provide a political base for economic operations and to provide guidelines for further analysis of local developments. (David A. Wilson, University of California at Los Angeles.)
27. "Effects of Regionalism on World Trade"—The effects on world imports and exports of the growth of international economic cooperation and the implications for the political situation in the countries involved of a further trend in this direction are studied. (Institute for Defense Analyses—Bernard K. Gordon and Donald Keesing.)
28. "Role of Women in the Developing Countries"—The first phase of a study of the changing economic, social and political role of women in the developing countries and its effects on U.S. Government policy. (Constance L. Pierson, chief researcher.)
29. "International Boundaries"—A series of studies giving the background description and an analysis of selected international boundaries in the Middle East. (Lewis M. Alexander, University of Rhode Island.)

30. "Foreign Students in Soviet Universities"—A study of the experiences of foreign students in Soviet universities and the effect of these experiences on their attitudes toward the Soviet regime. (Jane B. Webbink, Harvard University.)
31. "One-Party State Systems"—The first of a series of studies on questions of leadership, organization and political continuity in several African countries with one-party political systems. (Douglas E. Ashford, Cornell University.)
32. "The Foreign Policy of a Major Neutral Country"—A study of the foreign policy of a country which occupies a position of neutrality between East and West. (Karen J. Erickson, Harvard University.)
33. "Students and Student Organizations in Latin America"—A series of studies on the role of students and student organizations in several Latin American countries. (Taylor Peck, USIA, chief researcher.)
34. "The Evolution of a Leading Middle Eastern Political Party"—A study of the origins, ideology, leadership and organization of a leading Middle Eastern political party. (Fahim Qubain, the Middle East Institute.)

Response of Dr. Pendleton Herring, President, Social Science Research Council, to Questions of the Subcommittee on Science, Research, and Development

1. Great advances have been made in the physical sciences in the last quarter century, specifically in atomic energy, to the point where we have learned how to destroy the world—or at least, physically, how to destroy our civilization. The social question is, Have we learned not to?

1. If this question is taken literally, of course, it can only be dealt with in highly speculative terms. However, it does bring to mind a number of points that may be of relevance to the committee. Have we learned not to destroy our civilization? Here we must first analyze the "we" that is involved. Is the reference to the U.S. electorate or to mankind in general? Is the "we" the nations that possess atomic armament or all the nations represented in the U.N.? Is Communist China included in the calculation? Since I am not sure what assumptions the committee may have in mind, I shall not attempt to answer the question in these terms.

I think most of us would agree that there is no readily feasible alternative to the policy of deterrence which in recent years has maintained an uneasy balance in international affairs. The forces that would upset this balance and plunge the world into a cataclysmic war would, in my opinion, be the forces of irrationality or blind dogmatic ideology. The forces that would be more likely to restrain such actions would be those of reason, foresight, and calculation of desired outcomes. Whatever optimized the strength of reasoned judgment would be more likely to prevent disaster. It seems to me that in the nations of the world where education and science are highly valued and where men are free to express their opinions and to hold their rulers accountable, there is the greater likelihood of reason's prevailing. Of course, a host of qualifications surge to mind when one thinks of the errors of the past and of current disorders that call into question such assumptions about rationality. But what hope there is for the future lies, I think, in applying to the conduct of human affairs our full powers for analyzing facts, for facing realities, for choosing those alternative courses of action that seem to lead to adjustment and compromise rather than intransigence and conflict—in other words, attempting to apply to human relationships both the dictates of the ethical norms upon which the great world cultures rest and the skills we have for gathering relevant facts and applying rigorous methods of analysis to social problems and international issues. The social science disciplines are based upon such assumptions, such methods, such habits of thought, and it is necessary that in both the developing nations and highly traditional societies this more analyti-

cal, empirical—if you will, scientific—bent of mind be steadily enhanced. This does not imply that traditions and beliefs appealing to unselfishness and to altruism are one whit less important and needful.

My point simply is that the habits of thought and the intellectual skills that have done so much to order and to control nature for human benefit can and must be further developed and applied much more intensively in dealing with human behavior and social interactions. This has been said many, many times but it has not been said often enough or adequately responded to in the place of most influence: namely, the Congress of the United States.

The social sciences offer a disciplined approach whereby a more accurate picture may be gained of human behavior. It is not a method for producing easy answers but it is a way for arraying the evidence upon which more reasoned decisions may be based. The social sciences can ease the fetters of ideology, lighten the burden of superstition, deepen the understanding of social complexities, and enlarge the vision of human potentialities. These are no small services and if well performed may make unnecessary the facing of ultimate quandaries such as the fate of civilization. There is no end of imponderables, but the United States has gone far in reducing large problems to manageable stages. This is the path of experimentation, of ingenuity, of analysis. It calls for social inventiveness and social engineering. The economist, the sociologist, and the political scientist can help to make more effective the work of the businessman, the administrator, and even the statesman. But the division of labor will remain between the search for knowledge, for facts and theories on the part of the social scientist, and the utilization of these findings in the larger task of formulating and executing public policies.

2. What can the social sciences contribute to an understanding of the personnel characteristics that make some men good scientists, others good engineers, some good economists or businessmen, and equip still other men for other professions?

2. In a review of the over 300 recent research efforts concerned with the predictions of student performance, the findings do not warrant confidence in the predictive value of present knowledge regarding personality characteristics and their relation to academic studies. Not enough is known about personality characteristics to forecast how well an individual may succeed in his chosen career. As we know, some of our most successful leaders did not distinguish themselves in college.

The Russell Sage Foundation has just published "the Prediction of Academic Performance, a Theoretical Analysis and Review of Research," by David E. Lavin, a book that reports on the present state of the literature. In his conclusions the author recommends that, for the future, research be undertaken in a greatly broadened context. Useful predictions of college performance can be made on the basis of high school grades and standardized tests of academic ability, but prediction of college grades based on personality characteristics is particularly ineffective.

We cannot hope for too much in the way of indentification of specific characteristics that make a good scientist, a good engineer, or a good economist without an extensive research effort, because of two major complications. First, each of these categories includes quite a variety of persons, and properly so, for there are many different kinds of jobs

within each. The work of some engineers is almost exactly the same as that of some scientists, while the work of other engineers is hard to distinguish from that of some businessmen. The personal characteristics of a particular engineer may fit him for one kind of engineering duty and make both him and his boss quite unhappy if he is assigned to some other sort of engineering. Second, there are difficult problems in determining how successful a man may be in his job. These problems are particularly complicated in the areas of science, engineering, business, etc., because effective job performance depends upon so many factors and can be expressed in so many different ways.

However, if the committee's question is taken somewhat more broadly, to include all relevant personal characteristics, including intellectual abilities, rather than limited to what is usually regarded as personality characteristics then social science can contribute worthwhile insights as to the nature and distribution of such characteristics. A critical question, as David A. Goslin pointed out in his book "The Search for Ability" (Russell Sage Foundation, 1963), is the degree to which one is able to define precisely on the one hand the abilities (again broadly construed) required for the successful performance of a particular task (whether it be surgeon or airline pilot) and on the other hand construct a measuring device sensitive enough to tell whether a particular individual possesses more than an average amount of the abilities in question. With regard to some professions, for example fighter pilots, astronauts, etc., we have made substantial gains on both sides of the equation. For other professions, including those mentioned in the committee's question, we have some distance yet to go.

To indicate the range of work going on I would call to the committee's attention the following that of: Dr. Donald W. MacKinnon, director of the Institute of Personality Assessment & Research at the University of California, Berkeley; Dr. Donald E. Super at Teachers College, Columbia University; Dr. John Flanagan's Project Talent; Dr. John Holland at the American College testing program, Iowa City, Iowa; and Educational Testing Service's executive study and engineering study.

3. In your testimony on July 20 you characterized the social sciences as having been the "junior partner" in the National Science Foundation's overall program. Do you think they still are, "in spirit" as you said, and will continue so in the future? What steps would you recommend to alter the "junior" relationship?

3. The most fundamental factor in enhanced status is doing a better job. Obviously there is no better way to win deserved recognition. As in all "junior" relationships, time is the chief element in effecting change. To begin with, we must acknowledge that historically viewed as science, the social disciplines have been pursued over a briefer timespan and the greatest advances have been made in relatively recent years.

As already indicated, strengthening these fields must take place in our universities in the first instance. NSF has programs that are helpful and that should be continued. Moreover, the curve of increased support has been steeper in the Social Science Division than in other divisions of NSF. As the dichotomy between natural and social science diminishes and as new interdisciplinary relationships

develop, there will be also, I think, a change in spirit. I think the Foundation still has a large job to do about educating university people, including administrators and others from outside the social sciences, to understand that the NSF does indeed mean all sciences when it says "science."

The time has come for more Federal support for higher education and advanced research across the board rather than for favoring certain fields to the disadvantage of others. I realize that mathematics, engineering, and the hard sciences in general have had need for special attention, that very expensive equipment is often essential, and that vast public funds are indispensable; but now a reexamination of these imbalances seems in order. Federal support that more immediately and financially favors the physical sciences over the social sciences and humanities distorts their competitive relation within the universities.

4. For fiscal year 1964, a total of 2,892 grants were made by the Foundation, of which 246 were in the social sciences. For fiscal 1966, the corresponding figures are 4,300 and 350. Are these considered adequate relative to the support of the social sciences in terms of the funds available to the Foundation?

4. It is not possible to judge the appropriateness of support to a discipline from the number and percentage of project grants it receives; other information is also needed.

The important criteria are the intellectual and other values (including the significance for applied use) of additional knowledge in each area of inquiry together with the feasibility (including the cost) of acquiring new scientific knowledge in each subject area.

A related consideration is the needs of the institutions where research takes place (chiefly the universities and colleges) for financial assistance. It is reasonable for universities to expect assistance from the NSF for their social science activities to approach something like the proportional support they receive for their natural science activities. Support from other Federal and non-Federal sources must be taken into account, of course, but there is no reason to suppose that this would reduce the just claims of the social sciences.

Two factors, however, suggest that the percentage and number of grants for the social sciences might continue to grow:

(*a*) The continuing need to overcome the Foundation's late start in the social sciences generally and in certain of these disciplines specifically.

(*b*) The fact that NSF assistance to the social science research community comes about almost entirely by means of research project grants (and some grants for facilities).

As yet, the Foundation funds for support of national programs and national centers go entirely to the natural sciences. This may well be appropriate at this time, but the result is that in the social sciences project grants must carry a proportionately higher share of the total research support burden.

5. It was argued at the hearings that application of science and technology produces social as well as economic changes. However, the techniques for measurement of the social impact of technology have lagged far behind those for measurement of economic effects. What should the Foundation do to encourage research to improve the measurement of social changes caused by science and technology? What

should be the role of the Social Science Research Council in such a venture?

5. Methods for measuring the social impact of technology are less developed than methods for measuring the economic effects of technology, just as noneconomic measures in virtually all respects are less precise than economic measures. The Government produces through the work of the Census Bureau and a multitude of other statistical agencies a great array of indexes that can be used to indicate change in many aspects of our national life and of world affairs. More recently and with NSF support efforts are being made to develop noneconomic indexes such as opinion surveys and reports on attitude changes.

The Social Science Research Council has encouraged efforts at conceptualizing in theoretical terms the nature of social change and the indexes that empirical inquiry should produce if a dependable grasp of reality is to be attained. Much remains to be done.

A collection of essays, entitled "Social Indicators: A First Approximation," dealing with this question has been edited by Raymond A. Bauer of the Harvard Graduate School of Business in connection with the project for the American Academy of Arts and Sciences on the social impact of space. Here is a document of several hundred pages which is addressed directly to the congressional query. I would be glad to send a copy of this publication to the committee as soon as it is available.

Other studies bearing on the committee's interest are the following: "Technological and Social Change" by F. R. Allen et al. (Appleton-Century-Crofts, 1957) and "Diffusion of Innovations," by Everett M. Rogers (the Free Press of Glencoe, 1962).

6. Which fields of social science do you believe deserve enlarged support from NSF? More specifically:

(a) The present Foundation program in social sciences is divided between cultural and physical anthropology, archeology, demography, economics, economic and social geography, linguistics, political science, social psychology, and the history and philosophy of science. Does this division give satisfactory recognition to the principal social sciences? What changes would you recommend, if any?

6. (*a*) Sociology is also included in the NSF program. NSF support for psychology includes, besides social psychology, psychobiology, which is administered by the Division of Biological and Medical Sciences.

The list is now comprehensive, since many subdisciplines are assumed under these general headings and interdisciplinary work is of course included, except possibly for history. Some research in history is akin to social science research, but some is closer to scholarship in the humanities, and all historians do not agree in regarding their field as one of the social sciences. Support for research in history will presumably be undertaken by the new National Foundation on the Arts and Humanities. In any event, NSF's programs might be extended to include a substantial program in the more scientific historical research. Nevertheless, much work in history will continue to fall outside the sciences. The important consideration, of course, is to assure support from one source or another for good historical research. The

precise role of the NSF should be reexamined after the National Foundation on the Arts and Humanities gets underway.

(*b*) *Would it be preferable to organize the NSF's social science program according to great contemporary social problems rather than by academic discipline?*

(b) I do not think it would be preferable to organize the social sciences program in NSF according to great contemporary social problems rather than by academic discipline.

Not only are the training, interests, and knowledge of social scientists presently organized along disciplinary lines, but most social scientists would agree that in the long run the greatest steps we can take toward solving major social problems would result from advances in our general fund of knowledge regarding basic social processes. Support administered along disciplinary lines is also conducive to stable, long-run support. There need be no inconsistency between the present form of organization and special Foundation efforts to support research that is likely to be urgently needed for solution of particular social problems when this is necessary and when other Federal agencies do not have responsibility for this kind of assistance.

There can be a reasonable expectation that out of efforts to study realistically great social problems basic advances in knowledge can sometimes be made. I personally question the puristic attitude that deplores involvement in contemporary problems in the name of "basic research." The opposite hazard to be wary of is the tendency of some investigators with a strong reformist bent to confidently offer solutions and panaceas on the basis of inadequate evidence, superficial understanding, or wishful thinking. Task forces composed of interdisciplinary teams can give attention to special problems. They can proceed on an ad hoc basis, regrouping and recombining skills as the task in hand may require.

(*c*) *What advisory mechanism would you recommend to guide and assist the Government, including the Congress, the President and his scientific officers, and the Foundation, in identifying fields of social science for support and the levels of support amongst them?*

(*c*) To answer this question responsibly and realistically would require extensive discussion and consultation among the individuals and organizations that already have some measure of concern with the many issues involved. This calls for skillful staff activity over a period of months. My preliminary opinion is that much can and should be done to clarify the relationships of social scientists to the Federal Government and to enhance the contributions that their disciplines could make.

One pattern is that of the Council of Economic Advisers. Another incipient effort is that of the Social and Behavioral Science Division of the National Research Council of the National Academy of Sciences. The Brookings Institution has an outstanding record of advice to the Government. The services offered by the several social science professional associations with offices in Washington are helpful. Much is being accomplished on a day-to-day, ad hoc, opportunistic, decentralized basis. Whether more formal relationships, with greater visability and concerted leadership would be more effective, calls for study. Such a move might or might not prove efficient and fruitful. Well directed and financed, I think, a conspicuous agency representa-

tive of the social sciences and in close contact with governmental agencies and university social scientists would both aid officials and accelerate the development of social science research. For the social scientist to be simply called in as a consultant or treated as a grantee tends to limit or subordinate his intellectual contribution to the purposes of the governmental agency.

7. In your testimony you mentioned how the Foundation had to gain the trust of social scientists before they would turn to it for support. Does this imply alternative sources of support were available? If other funds are available, why should the Foundation consider extending its social sciences program?

7. In my testimony I was referring to the period when the Social Science Division was just getting established and gaining visibility. Research has almost never been solely dependent on public bounty; private philanthropy has normally provided the risk capital and the Government has stepped in at a later stage. Thirty, 20, even 10 years ago the great private foundations were directly supporting the social sciences as such. Today a number of very able social scientists do get support from private foundations for special projects, but the Federal Government is the most significant source though often under rubric of defense, space, health, education, international aid or relations, or some other major policy area. The NSF is the agency formally and avowedly supporting basic research in the social sciences.

8. What should be the respective roles of the Foundation, the Office of Education and the Social Science Research Council for education and training of scientists in the social sciences?

8. Under the existing administrative organization the Office of Education's responsibility for NDEA fellowships and the NSF program of training fellowships in the sciences seem satisfactory. Should there be a strong and separate Department of Education capable of providing research support and aid in graduate training in all fields, then the role of the NSF might be reexamined and perhaps modified. These relationships are too complex to admit of a categorical answer. The Social Science Research Council is prepared to review its own functions and objectives in the light of current governmental concerns with education and research.

9. This being the age of the scientific revolution, in what ways could the Government further educate the general public about science and technology? How much emphasis should the NSF give to research into the ways and means by which scientific discoveries are put to use?

9. There is already such a vast amount of information available to the general public about science and technology that I see no reason for the Federal Government to devise special programs to this end. As education is strengthened at all levels through Federal help the oncoming generation will be better prepared for the age of the scientific revolution.

The NSF through its concern with the history of science might well support inquiries "into the ways and means by which scientific discoveries are put to use." The Foundation can and now does support some research of this kind, including research by social scientists. It should support as much good work as it can find on the basic processes of diffusion of scientific knowledge and similar phenomena. It is

probably not the appropriate agency to "promote" the practice application of scientific knowledge.

The Foundation does expect scientific findings from research it supports to be published in the normal journals and other channels of scientific communciation.

10. Has the Social Science Research Council ever made use of the services of the Science Information Exchange? Have you contributed information to the Exchange?

10. No. We have not had occasion to make use of the services of the Science Information Exchange. Whatever information we have that may be pertinent is available to the Exchange.

RESPONSE BY DR. WALTER O. ROBERTS, DIRECTOR, NATIONAL CENTER FOR ATMOSPHERIC RESEARCH, TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

---

1. In your testimony on July 21 you spoke of man possibly altering the atmospheric environment to his detriment. How crucial is this problem? Is it an immediate danger? Do you believe the public realizes the problem?

1. In the July 21 testimony, two separate dangers were discussed. The first is that man is already altering his atmospheric environment in ways that may have long-range and widespread effects of which we are not now aware. It is clear that the growth of urban centers, the increase of general use of fossil fuels, and the more extensive tooling of soil, particularly in marginal rainfall areas, has altered the burden of dust and waste gases in the atmosphere. Many of the influences of these wastes are detrimental. The detriment is not only to the health of people and plants, but also to the cleanliness and comfort of life in population centers. The dangers of this kind of alteration of the atmospheric environment are immediate—the results are with us now, and the future can only see the progressive worsening of this problem, unless very major measures are taken. I am not sure that the public realization of this problem is in pace with the growth of the problem. Some gases like ozone and some of the nitrogen compounds can, under certain circumstances, be serious health problems.

What more widespread effects there may be—for example, from the apparent significant increase in carbon dioxide in the global atmosphere, put there by exhaust from fossil fuels—are as yet unknown. It has been theorized that the effect may be sizable, but no one can say with certainty today. The only prudent course is to undertake necessary research to understand the full effect and to assure that no adverse, irreversible processes will inadvertently be touched off.

The other danger is that large-scale weather and climate modification experiments may be tried in nature before their full effect can be predicted, and that damaging inadvertent modifications may therefore result. Further research is necessary before it is possible to give an unequivocal answer to the magnitude of this possible detrimental alteration. One can speculate that if large-scale modification of continental climate can be accomplished to the benefit of one region, there is possibility that it will simultaneously be to the detriment of another: or if one segment of the economy is benefited by increased rainfall, another may be damaged by this, even in the same region. Here the public perhaps fears the consequences even more than the realistic possibilities suggest may occur. But it is a realm of science in which speculation should be replaced by solid knowledge.

2. You stated that organizing and setting up the experimental global observing network such as was described to the committee by Dr. Hollomon is an enormous administrative and engineering task, requiring complex cooperation on both a national and international scale, and that the logical agency to manage such a program is the U.S. Weather Bureau. You also said that this type of information is essential before a large-scale weather modification scheme is attempted.

(a) This being the case, should the same government agency be responsible for both weather prediction and weather modification, or can these two functions be separated in any practical manner?

(b) How do you see the role of NSF in this regard, considering that it is charged by statute with a weather modification function?

(c) What should be the role of NCAR?

2. The importance of this network cannot be overestimated. Detailed information on a global scale is essential before one can accurately simulate, in an electronic computer, large-scale weather modification schemes. Once we have accurately judged the total effect on any large-scale weather modification scheme, the global data will help optimize the timing and controlling of large-scale operations. (We do not now know whether such operations will be successful; but if so, the global data will be essential to both the research and the operational stages.) Of course, the usefulness of adequate observational coverage of the entire globe for weather prediction is obvious.

(*a*) It seems clear to me that the U.S. Weather Bureau is in the best position to represent the United States in the operation of a global observing network, and to provide weather prediction. As for separating weather modification and prediction operations, it seems that one could, in principle, conceive of a practical manner of separating them. Since large-scale operational weather modification is several years away, at least, there is time for the Government to determine how the responsibilities of the United States as a whole, and of various agencies, would best be served. This will depend, to some extent, on what purposes are selected for weather modification, and the interest of the agencies involved. This, in turn, depends on what large-scale weather modification possibilities turn into realities.

There are, however, some shorter term weather modification possibilities (on which both the Weather Bureau and the Bureau of Reclamation are doing what might be termed applied research), and in which some overall governmental determination of responsibilities may require more immediate attention.

(*b*) Perhaps the salient point underlying an answer to this question as a whole is that a period of years will be required for basic research and for simulation of various large-scale weather modification schemes before any operation should be attempted. The NSF should play a central role in this research phase, and is particularly well situated to carry out the program of annual evaluation assigned to it by statute. A natural extension of this role would be to help bridge the gap between new knowledge and its application. But when the time comes for operations, the operating agencies should be in charge.

(*c*) As explained in my written testimony, NCAR's role in the atmospheric sciences is primarily directed at basic research; but, as the

trustees of the University Corp. for Atmospheric Research made clear in a resolution passed last April, our role also includes promoting the linkage between research and applications. Given the structure of U.S. science, this means promoting the linkage between university research and the long-term interest of various operating Federal agencies. As this complex role develops, NCAR can increasingly serve as the interface, helping to muster the strength of the university research community toward the solution of the many, complex basic research and developmental problems involved in a thorough investigation of the various possible modes of weather modification. (And I should point out that this includes many things beyond just cloud seeding to increase rainfall. Indeed, in the long run, this may turn out to be a relatively minor weather modification method—but the "long run" is difficult to predict.)

3. Is any work being done today on the supercomputer that you discussed? What do you think the cost of developing such a computer would be? Who do you think should properly undertake it?

3. The computer I described is one that a committee headed by Dr. Jule Charney of MIT recommended in a draft National Academy of Sciences report as being essential to both operational and research use of the data derived from the global observing network discussed in my answer to question No. 2. No specific work is now being done except informally by various groups (including NCAR) as to what the rough scientific demands on the machine might be.

In my own view, I feel that it would be ideal, providing it is feasible, for the cost of developing such a computer to be shared between industry, private foundations, and the Federal Government. The development work could very properly be guided by the NCAR scientific staff, in cooperation with university and other research personnel. The actual computer design and development must be undertaken by industry, with NCAR representing the potential customer interest—to make sure that the computer is properly designed to do the things that the users will want it to do. It is clear in my mind that the ultimate value to the Nation of a supercomputer is clearly justified as a major research tool to have it built at Federal expense. However, I would hope that these costs might be shared with other segments of the Nation.

4. You mentioned that large-scale weather modification schemes will necessarily be global in nature and are "likely to be international in consequence." What diplomatic or political repercussions do you foresee in such a program?

4. Because the atmosphere knows no national boundaries, it is clear that modification of the atmosphere in one country may well affect the climate, weather, or air pollution problems of another. And the larger the scale of modification, the surer it will be that we are confronting a problem of international character.

Indeed, it is clear that air pollution originating over one country is already affecting the atmosphere over another. This is spectacularly noticeable in Western Europe. If one succeeds in diminishing the intensity of hurricanes to the advantage of one country, one may adversely affect the available rainfall in still another. It is easy to see how conflicts of interest in weather could develop between nations. Such diplomatic and political repercussions have been foreshadowed

by the kinds of discussions that occur in respect to upper atmosphere modification (for example, the U.S. atomic tests in the very high atmosphere, which clearly modified the radiotransparency of the upper atmosphere). As a result, a few years ago the International Astronomical Union condemned the U.S. nuclear testing in the high atmosphere on grounds that it interfered with radio astronomy research.

Even if the possibilities are scientifically on weak ground, there will be fears that hail suppression in one country will result in decreased rainfall in another, etc. As a consequence I can see many diplomatic and political repercussions unless a great deal of the development—and perhaps the actual conduct of weather modification operations—are conducted under international auspices. The time is now, when large-scale international weather or climate modification is still mainly a scientific problem, that international mechanisms of cooperation must be forged. The closer we get to applications, the more difficult it will be to begin forging these ties.

5. You also indicated in your testimony that you are happy with NSF's support of NCAR, and that there is an excellent working relationship between the two. Dr. Hollomon, in his testimony before the committee, stated that "the support of NCAR should not be the unique responsibility of NSF," and he inferred that it should more properly be associated with the Environmental Science Services Administration. Would you please comment?

5. The intimate association between NCAR and the NSF is directly linked to NCAR's central responsibility to promote the development of basic research in atmospheric science, and its important related mission to support the growth of research and advanced teaching in the atmospheric sciences in the university community.

Because of this close association with NSF and with the university community, NCAR is also in a unique position to promote the linkage between the university community and the agencies; that is, between the basic research capability essential to progress in this field and the needs of the mission-oriented agencies.

This does not mean, however, that NCAR will not be properly and deeply interested in cooperation with ESSA. As a matter of fact, cooperation already exists between NCAR and the Central Radio Propagation Laboratory (soon to be affiliated with ESSA) in high-atmosphere research, and with the Weather Bureau (now associated with ESSA) in other areas.

Dr. Hollomon's view, as I understand it, is that the work of NCAR has such relevance to the operational mission of ESSA that the resources of the laboratory should be to a substantial extent available to ESSA upon call. He feels that only through support of NCAR can ESSA feel free to call upon the services of NCAR scientists in support of various appropriate ESSA missions.

It may well be appropriate, in the near future, for a division of NCAR's activity to be more directly concerned with applications of the atmospheric sciences. As this effort develops, the activities of the division might appropriately be supported by the Federal agencies that will call upon it in connection with their own prime missions.

But in the broad research and educational mission of NCAR—its principal goals at the present time—it seems to me that single-source

funding is the most controllable and the most efficient mode of NCAR funding. And NSF clearly is the most logical funding agency.

6. To what extent does NCAR function as an NSF laboratory?

(a) What controls does NSF exercise over—

Selection of projects and funding for them? Approval of subcontracts and orders?

Review and approval of construction projects for major plant and equipment?

Salaries and wages of NCAR staff? Reporting of results of NCAR research?

(b) Does NSF have title to all of the plant and equipment, or is title assigned to the agency that supplies funds for a particular time?

(c) What is the duration and character of the University Corporation for Atmospheric Research contract with the Foundation for the operation of the Atmospheric Research Center? Is this contract reviewed periodically? How far ahead does your commitment of funds run?

6. **NCAR** is an independent laboratory, operated by a nonprofit corporation composed of 21 universities. Its sponsorship and principal budgetary support come from a contract with NSF. We view our relationship as a partnership in pursuit of goals arrived at through a historical process in which the atmospheric sciences community as a whole has continually played the most important role. NCAR's program and plans are reviewed by various mechanisms drawing mainly on the university community.

Each year NCAR, with the endorsement of UCAR, presents its budget request to NSF, spelling out in broad detail its plans for research, facilities, and other activities. At this point, NCAR enters NSF's budget procedure, and its final fiscal allocation under its NSF contract depends on deliberations between NCAR and NSF, between NSF and the executive branch, and between NSF and the Congress.

In addition, we informally tell NSF of the results of our various review mechanisms, in order to assure NSF that NCAR's plans are continually responsive to the needs of the atmospheric sciences community and to the national interest.

With specific reference to the subquestions:

NCAR's program is developed through the mechanisms described above. NSF reacts to these plans. NCAR's budgetary allocation is the product of NSF's reaction to the plans and of NSF's own appropriation level. Once a fiscal-year allocation for NCAR is determined, NSF allows NCAR considerable latitude in determining how the funds shall be used to meet the program goals described in NSF's budget request on behalf of NCAR. NCAR submits an annual financial plan to NSF for approval after its allocation is received.

NSF approval of subcontracts is required for all cost, cost plus fixed fee, and time and materials subcontracts over $25,000. NSF review is also required for subcontracts for architectural, engineering, and construction subcontracts regardless of dollar amounts.

With relation to construction contracts, NSF requires that it be given at least 7 days' time for review of each subcontract involving construction work; unless NSF advises us to the contrary within that period, we may proceed.

NSF must also approve (*a*) subcontracts or leases for real property, aircraft, printing equipment, and other items the purchase of which is restricted by the Government; (*b*) subcontracts or purchase orders that have a "hold harmless" clause in favor of a third party.

These restrictions apply, of course, only to subcontracts for which NSF contract funds are used. For example, UCAR's own private funds have been used for a construction project this summer at the Climax Observing Station, near Fremont Pass, Colo., the site of which UCAR holds on a long-term lease from the American Metals-Climax Corp. We have, of course, informed NSF informally of this project—an extension to one of our observing-dome buildings.

NSF requires its approval of all salaries in excess of $17,500. A total amount for salaries is, of course, contained in NCAR's annual budget request and financial plan.

Reports of research results are usually published in the scientific literature. NSF requires no specific report except for a brief annual summary. However, NCAR's scientific production is reviewed by university-oriented groups, and NSF satisfies itself by informal means that these reviews are sound and thorough.

NSF has title to all the plant and equipment purchased, or developed, out of NSF contract funds. In addition, UCAR owns some $2,015,063 worth of capital items, and the following values are assigned to equipment developed in the past under contracts with three Government agencies: Air Force, $248,769; Navy, $184,224; NASA, $9,803.

The current contract between UCAR and NSF is a 5-year contract signed June 1, 1960. Prior to its expiration on May 31, 1965, a 6-month extension was signed, and it is expected that an additional similar extension will be agreed upon. Meanwhile, discussions of a new 5-year contract are now getting underway. Commitment of funds is a fiscal year at a time.

7. How is the basic research of NCAR related to the mission interests of the Federal agencies interested in the atmospheric sciences?

7. I assume the answer sought here is aside from the support of basic research in the physical sciences that will produce knowledge useful to the mission-oriented agencies—this, of course, is the justification for the basic research support these various agencies supply.

In the atmospheric sciences, basic research problems present major obstacles to progress toward applications of interest to every potential user agency. At this stage of the science, therefore, basic research progress in general is in the direct interest of all the agencies.

In addition, as stated previously, we are now considering various mechanisms to promote the linkage between basic research—at NCAR and in the universities—with the interests of the user agencies on the application of new basic knowledge being produced. Communication lines between NCAR and various other agencies are, in my opinion, actually quite good, and can serve as a firm base for a more focused effort.

8. What is the distribution of financial support for NCAR among the various Federal and non-Federal sources? What understanding exists about the duration of Federal support?

8. Virtually all of NCAR's operating funds at present come from Federal sources. However, UCAR carries on certain activities—for

example, a fellowship program—which are related to the same goals as those of NCAR, but are supported with private funds. It is UCAR's firm conviction that a modicum of privately supported activity helps protect the independence and university-community orientation of NCAR.

So far as an understanding with NSF about continued support is concerned, there is no formal guarantee, of course, beyond a given fiscal year. So long as NSF is persuaded that NCAR is an effective means of promoting progress in atmospheric research, we expect that NSF, within its own overall budgetary limitations and obligations, will continue to sponsor and support NCAR—but no longer.

9. Has NCAR ever experienced conflicting expressions of interests from Federal agencies funding its operations? If so, what was the role of the Foundation in resolving such conflicts?

9. We have not really had any conflicting expressions of interests. People are often impatient for NCAR to undertake many things that it has not had time and support to undertake, or that it does not have adequate manpower to undertake, but this is quite normal in a developing effort.

10. The point has been brought during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency X, agency Y, or both. Specifically:

> *(a) What guidelines or criteria has NCAR established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of your center's jurisdiction and, therefore, should, or should not, be supported?*
>
> *(b) If written criteria have been established, please submit a copy thereof to the committee.*

10. As described previously, NCAR program plans are generated by NCAR itself, rather than referred to NCAR by NSF; nor does NCAR advise on the propriety of projects among Federal agencies. This does not mean, however, that NCAR's research and facilities programs are not responsive to needs of the scientific community, and it has a number of internal and advisory mechanisms for monitoring those needs.

11. What is NCAR's policy concerning cooperation and collaboration with colleges and universities in basic research in the atmospheric sciences? How many visiting scientists are in residence at NCAR now? Of these, how many are working on projects that they have brought with them?

11. NCAR strives in a number of ways to achieve a thorough interaction among scientists from NCAR, the universities, and from other research groups. During the past year NCAR has had 34 scientific visitors in residence for periods of 4 months or more, as well as 166 for briefer periods. Other modes of interaction with university research programs are: (1) NCAR sponsored or hosted conferences to review results and plan future research in various fields; (2) the activities of the NCAR Facilities Division, which provides joint-use facilities in aviation, computing, and ballooning, and serves as national spare parts supplier to university-based M–33 radars; (3) the NCAR

"affiliate professorship" program, in which NCAR scientists and universities conclude 3-year agreements allowing the scientist to participate in teaching and other academic affairs on a part-time basis, and to be in residence for at least one semester during the 3 years; (4) a steady program of briefer visits to universities and colleges to give lectures or seminars; (5) summer employment of students in NCAR scientific programs. In addition, NCAR provides, from private funds, fellowships for graduate students to study at universities of their choices; and they are employed in NCAR scientific programs the summers before and after the year of fellowship study.

Scientists who visit NCAR may work on their own projects or participate in the work of an NCAR research group. Of those who do one of these, the latter predominates; but most do both. It is worth mentioning that they also often take back to their universities ideas for research projects which were generated while at NCAR.

12. What role is NCAR playing, formally or informally, as a training ground for new scientists and technologists in atmospherics?

12. Part of the answer to this question is provided in the answer to question No. 11. In addition, NCAR conducts a program of postdoctoral appointments for scientists who have received the Ph. D. in meteorology or in an allied basic discipline—chemistry, physics, mathematics, et cetera. Some of NCAR senior staff members have also come from these fields. One of the reasons for NCAR's existence is to help bring the atmospheric sciences more closely together with the basic disciplines, in order to broaden the field and make its attacks on problems more rigorous and comprehensive. In its interactions with universities and colleges, this broad view of the atmospheric sciences is being promoted in the ways described in this and the previous question.

13. You testified that "the heart of our country's basic research is in the universities." Do you see any danger of turning our colleges—that is, their science and engineering departments—into great research laboratories, at the expense of education?

13. There are dangers, but most universities are well aware of them, and this in itself is a help in combating them. To some extent, the need to create major facilities in order to carry on research contributes to these dangers. NCAR's facilities, created for the joint use of university researchers, help relieve some of the pressures in the atmospheric sciences.

14. Exactly how do you make use of the Science Information Exchange?

14. Our librarian informs me that NCAR, as an institution, does not make use of the Science Information Exchange.

15. Should NSF assume a more active role in the support of international science programs and projects? Might not U.S. aims, other than the development of pure science, be furthered thereby?

15. The prime objective of NSF should be the development of basic science in the United States. In many cases, however, NSF-supported activities in pursuit of this aim in the international sphere. Examples are the support NSF has given to activities of the International Geophysical Year and the International Years of the Quiet Sun. These ventures not only promoted good science, but undoubtedly served broad U.S. interests as well.

16. Do you see any advantage in efficiency of operation if NCAR were operated by a profit organization or as an in-house laboratory of the Foundation?

16. No. Our linkage to the university and basic research community is maximized through the present arrangement, and gives us a unique position from which to help relate basic research to application. In addition, the existence of UCAR allows us to undertake various activities promptly that might be delayed or prove impossible if there were not a minor source of private funds.

17. What contribution have the small college and the young unknown investigator to make toward the betterment of science? What specific effort does NSF make to assist them and take advantage of their potential?

17. A comprehensive answer to this question can be better supplied by NSF. NCAR's activities include the forging of ties with small, liberal arts colleges that do not have atmospheric science courses, in order to acquaint bright young science students with the opportunities and challenges of the field. It is clear that in this expanding field of science, small colleges and universities must contribute to the need for manpower.

As for the young, unknown investigator, every scientist of renown was once young and unknown.

18. What agency of Government, if any, has responsibility for the coordination of Federal research and development in the three fields of air pollution, soil pollution, and water pollution? Is such coordination a proper role for the National Science Foundation?

18. I am not familiar enough with the specific activities and plans of the various agencies to shed much light on this question. A definitive recommendation would be the product of a long, intense study.

RESPONSE BY REV. THEODORE M. HESBURGH, C.S.C., PRESIDENT, UNIVERSITY OF NOTRE DAME, TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

---

1. As a university administrator, are you satisfied with the balance of Federal support given to project grants, institutional grants, and science development grants? How would you attempt to reach an optimum distribution of funds for such support?

1. In general, I am satisfied that the National Science Foundation is trying to achieve an optimum balance. As more centers of excellence are developed, there will be a need for more project grants. This is not a straight line development. Large sums will be needed to improve 50 to 80 universities. Once they reach the higher level, there will inevitably be more demand for fellowships, traineeships, project grants, etc.

2. Is the level of support for social science grants adequate? Might not the percentage of the National Science Foundation's budget going into this area be increased?

2. Social science support has been growing. I do not believe it has yet reached a plateau where it might level off somewhat (not absolutely). I believe it should continue to grow rather rapidly until this whole area is better developed.

3. Considering the large increase in Federal funds for basic research at colleges and universities and the extension of that support into the social and behavioral sciences, what problems may confront the colleges and universities in retaining their independence?

3. Universities must guard their independence as they guard their lives. Otherwise, they lose that which makes them most valuable. With grants of money, there will inevitably be attempts (not malicious, but meddling) to get universities to do what the money granter thinks they should do, not what the university thinks it should do. All I can say is that the university must resist such pressures if it is to be true to itself. Some will, some won't.

4. What has been the experience of Notre Dame University with Federal project grants and contracts and other forms of support for research and education? Could you give us the figures on the amount of this support as a case example?

4. The material will be found in the committee file.

5. Since many Federal departments and agencies finance research and education among colleges and universities, do you think that the Foundation, in seeking new centers of excellence, should have authority and responsibility to coordinate grants and contracts for a specific institution, in order to obtain the greatest effect?

5. I am not sure that the National Science Foundation could or should coordinate all Federal grants. However, in studying the crea-

tion of centers of excellence, it should certainly take these grants into account—as an indication of excellence already existing and to avoid duplication or conflict of support.

6. To what extent have new Federal facilities at Notre Dame committed your future income in event of an early withdrawal of Federal operating support?

6. Not sufficient to ruin us if Federal support were withdrawn, but enough to cause us some very bad days and nights getting readjusted. Also, we would then be operating much less effectively than at present.

7. You spoke of the necessity for the National Science Board to delegate much of its early authority to the Director. In view of the rapid growth of the Foundation, would you not consider also that it is important for the Director to delegate much of his authority to other officials within the Foundation? To your knowledge, is this being done? Do you believe that Reorganization Plan No. 5 which gives the Director additional delegation of authority, will be beneficial in this way?

7. I believe the Director delegates to the extent possible and will do so even more the longer he is on the job. It takes more time than our new Director has had to see all of the potentialities in a rapidly moving field. I do not have Reorganization Plan No. 5 at hand, but would personally favor giving the Director additional power to delegate. May I add that there is much that he really cannot delegate—the overview of total National Science Foundation activity, priorities for the future, large and potentially troublesome decisions, contact with the Board and its main committees, budget planning and control, congressional and executive relationships, etc.

8. Do you believe that the retraining of science teachers is as effective as continuing their education immediately after graduation?

8. Effective in that teachers are at least already committed to education; students not yet. But I think we must do both to meet future demands.

9. Do you believe that NSF is overcontrolling its grantees by too many administrative requirements?

9. Controls tend to grow as the money involved and scope of programs grow. I personally favor broad institutional responsibility and a large measure of trust on the part of the Foundation, but it only takes one bad incident of irresponsibility to bring on pressure for additional control. The National Science Foundation certainly controls more now than it used to, but largely because of the above.

10. In an effort to spread its research grant money on a broad base does NSF, in fact, shortchange good projects by too limited support?

10. The only answer to this is a larger budget. One could, of course, tighten the scope, but then legitimate areas of science would be neglected. The National Science Foundation's really difficult problem is its mandate to support basic research in all areas of science and engineering, even where this involves large grants for national facilities in neglected areas. This inevitably squeezes the individual grant money in the total budget.

11. What long-term role do you see for the smaller colleges and universities in science and education? Has oncampus research become so important that those institutions which cannot afford it must sooner or later withdraw from education in the life and physical sciences?

11. I do not know the answer to this one—unless perhaps small colleges can establish research relationships with neighboring large universities and national research centers. The basic problem is that a good scientist who must do research to stay alive and grow will not go where this is impossible.

12. Should NSF increase its international scientific assistance to include support of research carried out by foreigners and/or Americans in foreign countries?

12. Under strict conditions: that the type of research is only possible abroad because of environmental conditions that are special—e.g. Antarctic; or the scientist (American) involved has to be kept alive scientifically while doing something abroad in the national interest. I could also see the National Science Foundation doing work overseas on contract support from agencies (like AID) that need the National Science Foundation's expertise for their special purposes.

13. With scientific talent in government concentrated in the executive branch, do you believe the scientific disciplines including mathematics and engineering should have more representation in our legislative bodies? Do you know of any effort by anyone to induce technically trained people to run for public office? Is this a proper educational objective?

13. Yes. No. Yes.

14. To what degree do graduate scientists and engineers drift away from their professions into other fields—such as management, trade or commerce, finance or other business. Is this good or bad? What can be done to improve career counseling?

14. To a rather large degree. It is both good and bad, depending on one's point of view. There is, of course, a movement in both directions. In societies like our own, freedom of movement is essential. Universities must stand for good values that will make career choices more meaningful.

15. At what grade level, in our modern educational structure, does a student chart his course toward science, engineering, social studies, business or the arts? Should the Foundation exert influence by the investment of support at this level?

15. The best that the National Science Foundation can do is to support good teaching at all levels, through teacher institutes, and the development of better teaching materials of all kinds. One would hope that other Federal agencies could promote similar progress in other legitimate fields of learning. Students should come alive to the excitement of learning in all fields and make their own choice of career according to their own talents and interests. This will happen for different students at different ages. In inadequate schools, it will never happen, to this Nation's loss.

Response by Dr. S. Dillon Ripley, Secretary, Smithsonian Institution, to Questions of the Subcommittee on Science, Research, and Development

1. As you know, in fiscal year 1965 fiscal and managerial responsibility for the Science Information Exchange were transferred to the National Science Foundation, which responsibility is exercised through a contract with the Smithsonian Institution.

(a) Was this transfer consistent with the current role of the Foundation as defined by the February 29, 1964, letter; namely, the coordination of non-Federal scientific and technical information activities and the development of Federal and non-Federal relationships?

(b) Does fiscal and managerial responsibility for the Science Information Exchange imply a measure of Federal coordinating responsibility?

(c) Was this transfer of responsibility regarded as "strengthening" the Exchange in accordance with the recommendations of the Presidential Scientific Advisory Council report?

(d) While NSF funds the operations of SIE, who has responsibility for professional supervision of its activities and maintaining the quality of its work?

1. The assignment of fiscal and managerial responsibility for the Science Information Exchange (SIE) to the National Science Foundation (NSF) was directed by Dr. Wiesner in his letter of June 6, 1963. The letter also provided that the operation of the SIE would continue under contractual arrangements with the Smithsonian Institution. Fiscal year 1965 was the first fiscal year for which NSF requested funding for the total SIE program.

(*a*) SIE collects and disseminates information about scientific research in progress over the broadest spectrum of scientific fields and handles research records from both Government and non-Government sources. On this basis, it would seem logical to assign fiscal and managerial responsibility for SIE to an agency with general responsibilities for, or a general interest in science. Thus it would be appropriate to assign responsibility to the National Science Foundation or to the Smithsonian Institution rather than to an agency that would be primarily mission oriented, concerned with limited scientific areas, and with far less responsibility for non-Federal relationships. It seems to the Smithsonian Institution that the assignment to NSF was consistent with the concepts expressed in Dr. Hornig's letter to Dr. Haworth dated February 29, 1694. We believe also that direct funding to the Smithsonian Institution would be just as consistent. NSF could still exercise—

> * * * leadership in affecting cooperation and coordination among non-Federal scientific and technical information services * * * and in developing adequate relationships between Federal and non-Federal scientific activities.

(*b*) This question is not clear as to "coordinating responsibility" for what. According to the SIE Charter, its mission is to collect, organize, and provide information on current research in order "to facilitate more effective planning, management, and coordination of the scientific research and development activities sponsored or supported by U.S. Government agencies." While the final responsibility for program coordination remains with the agencies themselves, it seems clear that SIE is responsible for collecting, organizing, and providing information that will assist and facilitate this process. The adequacy of support of SIE by the NSF will condition, in no small measure, the effectiveness of this service.

The Wiesner letter of June 6, 1963 provides for operation of the SIE by the Smithsonian Institution and funding by the NSF. It also provides for an Advisory Board to the National Science Foundation on SIE matters, with memberships from agencies with major research grant programs as well as the Smithsonian Institution. This is a coordinating mechanism. The Wiesner letter also stated:

> Accordingly, the National Science Foundation, with the advice of the Advisory Board, is charged with revising the present charter and providing the Committee on Scientific Information with recommendations for vigorous administrative action to insure proper technical inputs and support of the Science Information Exchange effort by all Federal agencies in the physical sciences.

(*c*) We assume reference is made to the "Report of the President's Science Advisory Committee of January 10, 1963," often referred to as the Weinberg report. The transfer to NSF provided for line item funding as recommended by the report. This could have been done by appropriation directly to the Smithsonian (which was seriously considered) or through NSF. The current responsibility for a strengthened program rests with the Office of Science and Technology, the National Science Foundation, the Smithsonian Institution, and the Science Information Exchange and the agencies represented on the Federal Council for Science and Technology and on the Science Information Exchange Advisory Board.

(*d*) Overall responsibility for SIE resides in the Office of Science Information Services, National Science Foundation, for the establishment of policy and scope in consultation with the Smithsonian Institution and the Advisory Board.

The Smithsonian Institution has full responsibility for operating the SIE, including professional supervision of its activities. The maintenance of a quality product is dependent to a large extent on the "diligence and care" of the various Government and private agencies cooperating with the Exchange in "collecting current efforts intelligence, and in forwarding it, suitably packaged, to the Exchange."

2. How complete, percentagewise, do you consider the substantive material comprising the Science Information Exchange to be? Can you give an estimate on this, in regard to both Government and non-Government inputs? In other words, how much of the U.S. technical information is the Exchange getting and how much is it missing?

2. We believe that about 90–95 percent of all unclassified basic and

applied research tasks supported or carried out (in-house) by the Federal agencies in life and social sciences is now being registered in SIE.

Since there is no sound estimate of the total number of Federal tasks extant, and since SIE has collected physical sciences records for only 2 or 3 years, we do not have firm basis in fact or experience for reliable estimates in this field. However, we believe that approximately 50 percent or less of the basic and applied Federal research tasks in physical and engineering sciences are now being registered. Registration of the major outstanding programs in NASA are anticipated in the next few months. DOD has promised only unclassified basic research; DOD is studying the question of unclassified applied research.

In regard to the non-Government input, we have no way of estimating the non-Federal national effort in terms of number of tasks. If it may be assumed that 60–70 percent of total R. & D. dollars are from Federal sources, the non-Government dollar level may be about half the Federal effort.

SIE has intensified its effort to increase the collection of non-Government research records, now that comprehensive Federal coverage is nearing completion. Efforts have been directed toward the major sources of information, i.e., the non-Government agencies that support or carry out substantial and significant research programs. Lacking a factual basis for estimating the total number of tasks extant, an estimate of percent coverage would be most unreliable. Our best appraisal of progress is, therefore, noted in general terms as follows:

(*a*) In fiscal year 1965, 125 private foundations and fund-raising agencies, such as American Heart Association, American Cancer Society, Hartford Foundation, and others, with research programs at the national level registered their research at SIE. More comprehensive coverage of programs from these sources is being pursued as fast as SIE resources and manpower will permit. One rough estimate suggests there may be as many as 5,000 or more private foundations and trust funds for research support in the United States. Many of these are probably quite small. From other sources, we have estimated that probably 200 to 300 of the largest may well represent the major contribution of this kind.

(*b*) State and city governments support research programs in such fields as public health and mental health, wildlife and conservation, agriculture, geology, oceanography, commercial fisheries, highway and building research, water resources research, sociology, regional and urban planning.

All the States do not support all these areas of research, and we have had insufficient experience to date to offer a reasonable estimate of the total number extant. In fiscal year 1965, 89 State agenices from nearly all 50 States registered some part of their research programs, and a total of over 5,000 registrations were received from these sources. Here again, collection is proceeding as fast as SIE can identify the programs, solicit and arrange for their registration.

(*c*) Many universities carry out substantial research programs supported by their own funds, local gifts, grants and contracts, besides the research supported by Federal and foundation funds. About 40–50 universities have been contacted to date and in every case have expressed their interest and willingness to participate. In fiscal year 1965, 36 universities registered some of their non-Federal research. This source has developed slowly, however, since projects are usually scattered throughout many different university departments and scientific disciplines. In a large university, identification and collection of the dispersed records is somewhat slow. We have noted, however, that universities are showing an increased interest in a central inventory for their own internal research management. Occasionally, SIE has been able to assist by providing computer lists of their projects already registered at SIE. When universities have developed their own inventory control points, collection and exchange arrangements with SIE can proceed more rapidly and efficiently.

(*d*) For some years, industry has offered token cooperation with SIE in regard to academic research grants that have no patent implications. Competitive secrecy, however, has not encouraged the registration of industrial in-house research. Several corporations have recognized, in principle, the mutual advantages of limited registration, and have suggested the feasibility of furnishing information on such projects as new analytical methods, and others where patent possibilities are remote. SIE has not vigorously exploited these sources since it may be some time before industry will contribute more than token registration.

Contact is maintained with industrial research groups for possible future participation, but greater effort is currently directed to other sources that promise more immediate response. Although in fiscal year 1965, 31 companies registered some research with SIE, the total number of such projects is small.

3. Can you supply for the record, on an agency-by-agency basis, the kind and amount of data the Exchange receives from Government sources; and also some measure of the extent to which these agencies make use of the Exchange?

3. Input and output by agency (see table).

Input and output by agency

	Input (fiscal year)		Output (fiscal year 1965)				
	1964	1965 [1]	Special projects	Administrative requests	Subject questions	Investigator reports	Automatic distribution
Federal:							
Agriculture	9,563	9,808	1	6	108	13	
AEC	2,567	1,392		5	20	992	8,729
Commerce	1,001	2,489	1	1	26	101	1,296
Congressional				6	43	127	
DOD	9				5	1	
Army	1,835	185		2	196	8	530
Navy	2,227	1,665		2	100	34	278
Air Force	3,161	1,430	1	1	171	221	
FAA	501	9			9		933
HEW	20,827	18,988	4	113	437	28,003	257,994
Interior	3,022	3,630	3	4	199	11	107,807
Labor	94	69			6		398
NASA	782	418			24	145	238
NSF	4,662	4,127	3	2	98	3,437	2,651
SI	1	297		4	16		
State	30	23		9	13		38
VA	6,580	6,199	1	20	146	6	43,505
HHFA	1						
TVA	125	105					
Other Federal			2	6	114	1	
Subtotal	56,988	50,834	16	181	1,731	33,100	424,397
Non-Federal	10,530	11,280		94	3,656	2,399	5,687
Grand total	67,518	62,114	16	275	5,387	35,499	430,084

[1] Grants are recorded by the Science Information Exchange for the fiscal year in which the grant is awarded. The grants listed herein for fiscal year 1965 represent only those that have reached or cleared SIE as of this date. All records for a fiscal year do not reach SIE until several months after July 1.

GENERAL NOTES AND DEFINITIONS OF TYPES OF OUTPUT

NOTE.—The kind of data received from Government sources is shown on the attached sample of the notice of research project (NRP). This is the input of the Exchange. About 75 percent of the Federal registration is furnished on NRP's. The remaining 25 percent comes to SIE in various stages of completeness and format.

NOTE.—About 25,000 NRP's describing pending research proposals, i.e., applications for grants, are received annually from several agencies. When notified of action by cognizant agencies, rejected proposals are destroyed; accepted proposals are then registered as active projects. These records are not included in the input statistics reported in the attached table.

Definitions

Special projects.—Specially indexed compilations for publication or specialized distribution involving broad interdisciplinary areas and requiring extensive committment of SIE resources. (Example: Production of the water resources research catalogs for publication by the Department of the Interior. (All of this category are for Federal offices.))

Administrative requests.—Requests for information involving no subject dimension, compiled according to source of support, location of research, or accession number. (Example: Tabulation of all federally supported research to the State of California by performing institution. (89 percent of this category are for Federal offices.))

Subject questions.—Requests for information that specifically involve subject matter dimensions. (Example: All current research on the kinetics of conversion of anhydrous boron oxide to boron nitride. (80 percent of this category are for Federal offices or Federal contractors and grantees.) Note: The table shows a volume of subject questions services for non-Federal offices. Samples indicate that at least 43–50 percent of these offices are performing federally supported research in the general subject area.)

Investigator reports.—Requests for information concerning research being performed by a specific investigator or investigators. (Example: All research being performed by David T. Roberts. (99 percent of this category are for Federal offices.))

Automatic distribution.—These are numbers of extra copies of NRP's requested by agencies for their own files and internal records.

PROJECT NO. (Do not use this space)
GP 77
AT(30-1)-2672

SUPPORTING AGENCY: Division of Research
United States Atomic Energy Commission

TITLE OF PROJECT: Mechanism and Rate Study of Butadiene Produced Using C^{14} Labeled Intermediate Compounds.

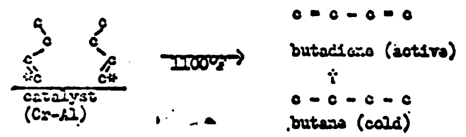
Give names, departments, and official titles of PRINCIPAL INVESTIGATORS and ALL OTHER PROFESSIONAL PERSONNEL engaged on the project.

Department of Chemical Engineering:
John Happel, Professor of Chemical Engineering
Y. Okamoto, Research Scientist
D. Desouza, Research Assistant

NAME AND ADDRESS OF INSTITUTION: New York University
University Heights
New York 53, N.Y.

SUMMARY OF PROPOSED WORK -- (Approximately 200 words. Omit confidential data.) In the Science Information Exchange summaries of work in progress are exchanged with government and private agencies supporting research, and are forwarded to investigators who request such information. Your summary is to be used for these purposes. Please make your summary substantive in nature, rather than generally descriptive.

In the dehydrogenation of butene-1 tagged with radioactive beta-emitting C^{14} in the 1- position, it was found (1) that cold butane and radioactive butadiene were produced:



If this observation is correct, it would rule out the class of single site mechanism and favor dual site mechanism, that required adjacent activated molecules.

It is the purpose of this proposal to establish this most unexpected observation using the radioactive butene tagged with C^{14} in the 1 or 2 position as the starting material, and further, to determine the position of the radioactive C^{14} atom in the butadiene produced.

(1) This result was obtained at New York University under AEC Contract AT(30-1)2672.

SIGNATURE OF PRINCIPAL INVESTIGATOR John Happel John H. Happel

Submitted for period beginning January 1963

4. Last year the Select Committee on Government Research found the future effectiveness of the exchange was endangered by the proliferation of interagency and intra-agency information clearing centers. Has this situation changed during the past year?

4. SIE has always been of the opinion that intra-agency clearing centers should be and eventually would be organized and specialized to serve internal agency management needs. Cooperative exchange arrangements with SIE could then channel all agency information to SIE that would be appropriate for interagency needs. SIE would then direct its major efforts to interagency exchange. Such arrangements should avoid any serious duplication, overlap, or conflict since

information for internal agency management is handled differently and in much more detail than the same basic stock of information would be handled, organized, detailed, and used for the broader aspects of interagency information exchange. A case in point is the successful collection and organization by SIE of a broad spectrum of basic and applied research related to water resources. This embraces scattered interdisciplinary aspects, includes selected segments of a number of applied research fields, and is extracted from the research programs of more than five Federal agencies. In addition, significant programs are contributed by 30 different State research agencies.

In our opinion, considerable progress can be made in such cooperative exchange arrangements with intra-agency systems.

Interagency exchange systems do not yield quite as clear-cut division of mission and purpose. In cases where a limited scientific discipline or applied field is concerned, a reasonable modus operandi for coordination and cooperation can be worked out. For example, negotiations are now underway with a highway research information center for full exchange of pertinent data, as well as coordination and cooperation in the collection of research records. The highway research information center, however, specifically serves the detailed needs of its user-community, while SIE can select those segments of highway research in the earth science and construction materials that are needed by SIE for information services in water resources research. By the same token, selected aspects, such as research on traffic patterns, by suitable modifications, can be adapted to SIE's organization of research information for urban renewal research.

Other interagency clearing centers that have recently appeared present the possibility of some overlap with SIE. Where the main emphasis is on report literature and the documented research results that are not handled by SIE, there would be only minor areas of overlap. Working agreements for coordination and exchange cooperation have been recently developed with the Department of Commerce Clearinghouse and the National Referral Center. These arrangements are intended to identify and eliminate any duplication in areas that seem likely to overlap. Research programs from the Bureau of Reclamation, Department of Interior, and the Office of Antarctic Program, National Science Foundation, are now being registered. Basic and applied NASA programs are to be registered in the next month and delivery of the basic science part of DOD research is expected about October or November.

5. Supplementing your testimony, are the organizational relations of the Exchange and the Foundation with other departments and agencies adequate to obtain information on in-house research projects as Government laboratories as well as the work they sponsor through grants and contracts?

5. Much of the in-house work of the Federal agencies has been registered at SIE during the past several years. Members of the Advisory Board representing each agency have traditionally been SIE's point of contact at each agency to assist and facilitate the input of all research projects, inhouse, as well as extramural grant and contract programs. The major factor for getting this input has been the interest and willingness of the agencies to fully support SIE's program

and get the job done, and on the position and influence of the Advisory Board representatives within their own agencies. Dr. Wiesner in his letter of June 6, 1963, requested the agencies to designate a high-level official for the Advisory Board representative, preferably from a research arm of the agency. This helps achieve appropriate organizational relationships to obtain in-house research.

6. What has been done administratively since the issuance of the Elliott report on R. & D. information to improve the efficiency of correlating and disseminating scientific information?

6. A number of internal administrative steps were initiated by SIE to increase its efficiency and effectiveness before and since the issuance of the Elliott report. SIE had a management survey in the summer of 1964 which resulted in a number of internal management improvements. At present, a survey of user requirements is underway by an outside firm.

However, we believe this question refers to administrative actions taken by OST, the FCST, and NSF concerning the Government-wide aspects of the correlation and dissemination of scientific information. SIE has information only on current efforts work. The complete agency inputs have not come through on current research in the physical sciences in DOD and NASA as yet; information has been disseminated in new formats to meet new needs as discussed in the comment on question 7.

7. Are the actual dynamics of the communication process relatively stable, or forever changing? Are enough funds available for carrying out experiments to apply new knowledge, techniques, and equipment for more efficient information retrieval systems?

7. There are two aspects to the dynamics of the communication process. From the viewpoint of present information retrieval systems, there are, indeed, rapid changes in computer developments and their applications to information retrieval. There is also rapid progress in theoretical systems design and concomitant application to practical operations. On the other hand, there appears to be a significant and rapid change in the nature and sophistication of user demands and user requirements, for which new approaches to systems design may be needed. This is more on the side of the advanced intellectual aspects of information needs rather than operational mechanics noted above.

A case in point is the new and growing demand in the past year at SIE for the extensive organization and cataloging of broad multidisciplinary collections of all research related to such varied fields as water resources, urban renewal, oceanography, pesticides, building research, and others.

SIE has had normally about five experimental studies more or less continually underway to explore and develop the means and methodology to meet these changing requirements, as well as the ever-present problems of increasing its operating efficiency and economy. However, SIE has been funded in recent years primarily as a service function.

8. Do you believe that NSF's grants are made for too short a period? Are they spread too thin in order to accommodate a larger quantity of proposals? Is NSF now requiring too much by way of administrative regulation to permit the best work on its grants?

8. NSF grants are usually made for the period of time requested by the applicant, and for not more than 3 years. However, the applicant is advised whether or not he can seek renewal with additional funds at the termination of the period, and he is often encouraged to seek extensions of time without additional funds. Although the amounts of money requested by applicants are often reduced in the final grant, this is done on the advice of outside consultants and is not intended to "spread the money thin." The grants are adequate in most cases. Considering the volume of money involved and the necessity to seek advice widely, the administrative regulations involved are minimal, and complaints from the scientists about them are seldom heard.

9. The point has been brought out during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say by agency X, agency Y, or both. More specifically:

(*a*) *What guidelines or criteria have been established by the Smithsonian Institution to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the agency's jurisdiction and, therefore, should or should not, be supported by the Smithsonian?*

(*b*) *If written criteria have been established by your office, please submit a copy thereof to the committee.*

9. The Smithsonian Institution has very little money for the support of outside research. On the rare occasions when the Smithsonian has supported research by outsiders, it has often been because of close tie-ins with staff interest.

Criteria for support of research by any agency can be most easily related to the mission of the agency. The qualified administrator of grant or contract funds must first decide whether the proposed research promises to contribute most directly to the mission of his own or another agency. On this basis research related to disease problems may be referred to NIH or that providing information with direct application to disposal of nuclear wastes may be referred to the Atomic Energy Commission.

Where a research proposal seems to make no special contribution to any other agency it would seem to fall within the purview of the NSF. The Smithsonian Institution, although having a broad charter, generally would select projects promising to give information in support of its research bureaus.

In some cases, the staff of the Institution may elect to support a project of doubtful acceptance by another agency because of special Smithsonian interest.

No written criteria on this matter exist within the Smithsonian Institution.

10. In your annual report, you noted that to overcome shortages of competent investigators, the Institution has begun studies of expanding educational opportunities in neglected areas of the natural sciences. What contacts have you had with the Foundation about such training, and with what results?

10. The Institution receives reports and participates in studies sponsored by NSF to describe the manpower situation in science. The shortages of systematists in biology as well as other types of scientists have been revealed by NSF studies.

NSF support of scholarships and fellowships particularly at the graduate level is restricted to academic institutions. We have been informed by NSF that we are not eligible to participate in their fellowship program as a project agency. On the basis of our discussions with NSF we are considering the establishment of a fellowship program to meet our special manpower requirements.

11. The Smithsonian provides some support for training in broad areas of biology and anthropology not otherwise available under existing university programs:

(*a*) *Has the Institution been able to obtain assistance for this from the Foundation or the Office of Education?*

(*b*) *Does the Institution believe such training should be the role of the Foundation?*

11. The Smithsonian conducts basic research in the sciences. In biology and anthropology, Smithsonian research is either not at all pursued in university research centers or is given inadequate attention there. Because we believe that biology and anthropology are vital areas of research, and that scientists and scholars should be given the opportunity of learning more about them and pursuing their own research objectives in them, the facilities of the Institution are made available to advanced research scientists, and to graduate students who plan to enter these fields of study. Toward this end, the Smithsonian has been developing plans for a postdoctoral visiting research associate program and a predoctoral internship program.

(*a*) Although the Foundation has given the Institution an $11,000 grant for undergraduate education for the summer, 1965, however, the Institution has not obtained direct assistance for these above programs from the Foundation or from the Office of Education. However, scholars granted fellowship funds through an academic institution by the Foundation or by NDEA programs in the Office of Education may use them for salary support while being trained at the Smithsonian. In such cases, the Smithsonian generally has to support from its own funds, facilities, equipment, and supplies for such scholars.

(*b*) Since the NSF grants fellowships only through general competition (not by specific fields) it has become necessary for many agencies to establish their own fellowship programs to meet urgent needs in a special field (i.e., AEC, PHS). Since certain areas of scientific research at the Smithsonian are particularly in need of support, we are (as mentioned above) considering establishing a special fellowship program.

12. What is the nature of the Institution's cooperation with universities mentioned in your annual report? What has been learned from this experience that is pertinent to future activities of the Foundation?

12. The Institution's cooperation with universities is responsive to longstanding legislation that the Institution shall be responsible to see that the national collections are studied. Encouragement of aca-

demic involvement in the Institution's programs increases the availability of scientific manpower and brings new concepts and new interest to our programs.

Each cooperative arrangement is designed to meet a particular problem in a research field, both for the university and for the Institution. It may involve members of Smithsonian departments taking leave from their posts to teach or do research full time for a semester on the campus. In other cases, students initiate or continue thesis research under the direction of an Institution staff member. Complete courses—lectures and seminar meetings—may be held in Smithsonian facilities with Smithsonian staff members serving concurrently as off campus staff members of the university.

Some of the programs allow students to work closely with full-time research scientists on unique collections. In the arts and humanities similar programs enable students oriented primarily toward books to become involved with the actual sculpture, the actual musical instruments, that make up the discipline in which they are studying.

The Foundation has long encouraged cooperative arrangements between and among universities. They have encouraged our entering such agreements and contributed to the universities part of the cooperation. Thus our experience verifies the validity of the NSF program.

13. Has the Institution in its Department of Science and Technology investigated the relationship between basic and applied research and development on one hand and the national economy, and perhaps regional economies, on the other? How should such responsibilities be divided between the Smithsonian and NSF?

13. The Smithsonian Institution has not investigated the relationship between basic and applied research and development and the national or regional economies.

The Department of Science and Technology of the Museum of History and Technology performs research in the history of technology and the physical sciences primarily related to the development of the sciences and scientific instrumentation and to the evolution of engineering, machines, tools, and processes. These studies include occasional reference to the cultural effects of scientific and technological development but they contain very little with regard to the relationship between these developments and the national and regional economies.

The staff envisions the possibility of the addition of an economic studies unit to extend the usefulness of its present programs. However, no plans have been made for this activity and the Smithsonian has not studied the matter in sufficient depth to answer the question of how the responsibility should be divided among various agencies.

14. Your report mentions an effort to contribute to the efficiency of research through studies of ways to promote the application of data processing, technician employment and training, improved cataloging methods, and more rapid indexing and retrieving of information in the biological sciences.

(a) How do these relate to the Foundation's responsibilities for training and education and for scientific information?

(b) Is the study of technician training likely to indicate a need for greater effort to provide qualified technicians and perhaps a role for the Foundation in such training?

14. (*a*) We share the concern of most agencies with the use of data processing techniques for the increase of output and efficiency. We have sponsored several studies of the applications of storage and rapid recall of data to museum operations. We are constantly on the lookout for ways to improve our cataloging and indexing systems in order to provide more rapid access to the collections and study materials.

Recently, we have broadly advertised our plans to develop a coding system for biological names which will enable us to locate and compare data in our collections from several directions. The NSF is strongly interested in this program since it has supported projects with related aims. NSF encouragement and consultation in the effort has been a factor in determining the method of approach and the continuing work. Their advice is sought and the results of the work are considered jointly with them for application elsewhere in the museum and to other scientific areas.

(*b*) The employment of technicians in the museum has been carried out within general Civil Service regulations. The new technician has generally required extensive and continuing on-the-job training before becoming proficient in this type of employment. Although no courses presently exist, the Institution is seriously considering the establishment of training courses. The increased use of more technicians should increase the efficiency and output of scientists on our staff.

Generally it has not been a practice of the NSF to support technician training, such support going to the education of scientists. If our museums along with others use more technicians in the future, we will consider with NSF who should develop curriculums and support courses for technician training. In the meantime, we will continue to experiment with various on-the-job training techniques for our new technicians, making the results available to NSF. In the past, NSF has provided funding support where special training concepts are involved.

15. What is the level of effort of the Smithsonian's study of science and technology and how does this compare with the Foundation's support of research in the history and philosophy of science?

15. The Department of Science and Technology has a staff of 13 historians. This staff performs research studies comparable on a man-to-man basis with those performed in a university department. The Smithsonian staff is engaged in other curatorial duties including documentation of collections, the planning of educational exhibits, the preservation of collections, and furnishing information in response to inquiries received from historians, students, and the public. Approximately one-third of the staff's time is devoted to the study of the history of science and technology. The staff of the department is larger than that of any university department of history of science and technology.

The cost of the Smithsonian Institution effort calculated on the basis of one-third of the time of the historians involved was, in 1965, approximately $135,000 for salaries and supporting services.

In response to the inquiry made, the Office of Social Sciences of the NSF reported that it supported in 1965, 36 research projects in the history and philosophy of science in the amount of $891,000.

16. To what extent did the early fostering of land-grant colleges contribute to the development of American industrial technology?

What lessons do you see in this experience that should be kept in mind by the Foundation in carrying out its programs of institutional support?

16. The NSF program of institutional support is designed to provide that funds will be available for imaginative research by creative scientists and scholars, who because of lack of experience, narrow background of acquaintance, and/or recent graduation from a university are not likely to receive a research award from the Foundation.

The land-grant colleges utilize fertilizers from chemical industries and equipment and tools from mechanical industries. They encourage new processing industries for agricultural products. They have contributed to the growth of transportation related industries.

Thus, the land-grant colleges have broadened the base of support for agricultural sciences and it is anticipated that NSF institutional support will broaden the capabilities and competencies of today's universities. As concentration on agriculture resulted in industrial developments and as the emphasis on space has resulted in the production of sophisticated vehicles for entry of that environment, it is expected that industry will contribute to the solution of various types of equipment and other problems raised by the NSF's institutional support.

RESPONSE BY DR. ERIC A. WALKER, CHAIRMAN, NATIONAL SCIENCE BOARD, AND PRESIDENT, PENNSYLVANIA STATE UNIVERSITY, TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

1. The National Science Board was characterized by Dr. Waterman in his testimony as "a unique body for dealing with policy matters." and he advocated more use of it within the executive branch by such agencies as the Office of Science and Technology, the Federal Council for Science and Technology, and the President's Science Advisory Committee. What is your comment?

1. Obviously this was a great opportunity for the National Science Foundation, but one it did not seize.

Although there have been a few reports providing guidance for all levels of the Federal Government, these have been few and far between. A notable exception was the report authored by Dr. Bolt when he was assistant director of the Foundation entitled "Investing in Scientific Progress." But, unfortunately, the National Science Foundation, to outsiders, seemed to lack the will to do much in this direction, although it was admirably equipped at the top levels with a board and divisional committees to do so. Nevertheless, the proper supporting staff was not easily available and the reports were not produced.

Eventually, Government agencies turned elsewhere for background and policy reports; to A. D. Little Co., to the National Academy of Sciences, and so on. Reports such as "Ground-based Astronomy—A 10-Year Program" (the Whitford report) and "Economic Benefits From Oceanographic Research" (a National Academy of Sciences-National Research Council publication) are examples. By now few people expect the Board of the National Science Foundation to provide such studies or such guidance.

Recent attempts to provide guidance under the new Board structure are:

(*a*) "The Role of the National Science Foundation in Support of Research in Ground-Based Astronomy" proposed by Committee III and approved by the Board at its 100th meeting (May 1965). (NSB/C-III-65-13.)

(*b*) "Use of Digital Computers in Universities and Colleges" proposed by Committee I and adopted by the Board at its 100th meeting (May 1965).

More of this latter kind of guidance is needed, but to produce them is a heavy burden on the Board which it cannot carry without additional help.

2. As you know, Reorganization Plan No. 5 would abolish the statutory divisional committees. In his appearance before the Executive and Legislative Reorganization Subcommittee, Dr. Haworth stated that the number of divisional committees has proved cumbersome; and

he cited as an example that under the NSF Act three committees were now required to deal with scientific personnel and education matters, whereas one committee was all that was necessary.

(*a*) *Rather than abolish all eight divisional committees, why didn't the NSF just reorganize the three committees concerned with scientific personnel and education?*

(*b*) *Have the divisional committees really fulfilled their original purpose?*

2. The history of the divisional committees is an interesting one. The original National Science Foundation Act (Public Law 507 (1950)) required a committee for each division of the Foundation, and went on to specify the terms of office and said that such committees "shall make recommendations to and advise and consult with the Board and Director with respect to matters relating to the program in its division." A Board directive dated 1960 spelled out in more detail the duties of the divisional committees assigning them a number of important duties through which they were to assist the Board and Director in their operations. At least once each year the divisional committee chairman was to be invited to a meeting of the Board in order to report on, and discuss the activities of his divisional committee. Moreover, at one time the Board suggested that annual meetings be held of all the committee chairmen to discuss topics of common concern to all committees, or programs which were of concern to all committees. Five such meetings were held.

There have been occasions when joint meetings have been held between full committees of the Board and the divisional committees. The last such meetings were those of the Biological and Medical Sciences Board Committee in 1963, and the Scientific Personnel and Educational Board Committee which met with its corresponding divisional committee in the same year.

The present practice is to have a member of the Board attend each meeting of the divisional committee. A staff member reports to the Board on the deliberations of the divisional committee and the Board member usually offers further information and comments.

Thus it is quite evident that the committees are an invaluable arm of the Board.

However, the Board of the Foundation did not vote on the abolition of the statutory requirement for divisional committees. The reason behind this are quite clear cut.

In the Reorganization Act of 1960 [1] the divisional committees reporting channel was shifted from the Board and the Director to the Director alone.

At the September 1964 meeting the Director informed the Board that he "was considering the possibility of requesting, through the Reorganization Act procedure, an amendment to the National Science Foundation Act which would relax the rigid requirements relating to divisional committees by repealing section 8." At the May 1965 meeting the Director reported that the President had submitted Reorganization Plan No. 2 which included such provisions to the Congress on May 13, 1965. Reorganization Plan No. 5 of 1965 which abolished the requirement for the divisional committees became effective on July 27, 1965.

[1] The Reorganization Plan No. 2 of Mar. 29, 1962, establishing the Office of Science and Technology, provision No. 4 of which was "the divisional committees will report to the Director rather than to the Board and the Director."

I do not think the Board expects that the divisional committees will be abolished. If they are, an important link with the scientific community will be severed.

3. The point was brought during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency X, agency Y, or both. Specifically:

(a) What guidelines or criteria has the Board established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of NSF's jurisdiction and, therefore, should, or should not, be supported by the Foundation?

(b) If written criteria have been established, please submit a copy thereof to the committee.

3. From time to time the Board has set forth guidelines as to the extent of the Foundation's support to be granted in certain areas. For example, the Board at its 77th meeting (May 1962) approved a list setting forth the types of engineering projects which the Foundation would be prepared to support under its expanded program (see NSB–491, app. VII) which follows:

APPENDIX VII

POLICY RELATING TO THE SUPPORT OF PROJECTS IN THE ENGINEERING SCIENCES

The announcement some months ago of the establishment of an Engineering Section within the Foundation to supersede and absorb the engineering sciences program has resulted in a number of inquiries concerning the essential significance of this move. The news release that was issued at the time of the establishment of the section generally described the revised scope of the program. In view of the interest generated, we should be prepared to support meritorious reresearch projects along such lines as:

(*a*) The development of principles and techniques in systems engineering design.

(*b*) The development of principles and a philosophy for creative engineering.

(*c*) Interdisciplinary research related to such matters as biomedical engineering, transportation, urban planning, fire prevention, etc.

(*d*) The principles of generation and control of energy systems and information systems.

(*e*) Analysis and synthesis of processes and systems which contribute to mastery of the environment.

It is recommended, therefore, that the Board adopt the following resolution:

"*Resolved*, That the National Science Board considers that intellectual pursuits at educational institutions intended to advance significantly the basic engineering capabilities of the country are eligible for support by the National Science Foundation as basic research in the engineering sciences. Such work must be of a true scientific nature and not routine engineering practice, and must meet the usual NSF standards of originality and excellence."

ALAN T. WATERMAN, *Director*.

4. What science policy function does the Board now serve that is not adequately provided for by existing organizational arrangements within the Executive Office of the President?

4. This is a very difficult question to answer because it assumes that science policies being developed within the Executive Office of the President are generally known. This is not so.

There is no doubt that all science policy functions could be centralized in one office or department. However, if they were, we would have in fact, if not in name, a Department of Science, with all policy and all control of funds for science channeling through one source. There are many scientists who feel that there is strength in having a diversity of sources of funding, and a diversity of policies in dealing with scientific problems and the academic community.

5. In your judgment, should NSF be given greater operational authority? Why, or why not?

5. I believe that the National Science Foundation should be given greater authority. This, however, would require a permanent and specially selected staff. The analogy for this course of action is the Naval Research Laboratory, which is funded through the Office of Naval Research. The Laboratory, which has an excellent reputation, can often provide a technical assistance to the Office of Naval Research and it always provides a standard against which some contract or grant research can be measured. The National Science Foundation does not have such an operations staff of Government employees in any field, but such a capability in oceonography would have been extremely helpful in establishing the Mohole project.

If the National Science Foundation gets into the support of large engineering research projects, such as weather modification, water retrieval, transportation, and the like, it will find it difficult to write such large contracts with industry or with universities. National laboratories operated by the Foundation would be one answer.

6. Do you consider the social sciences as positively within the purview of the Foundation? How does the Board define NSF's role for support of research in the social sciences? Is this role likely to increase or decrease?

6. I personally consider the social sciences as certainly coming within the purview of the Foundation, but at times it seems the Foundation has been a little timid in accepting this responsibility.

On December 1, 1958, and January 23, 1959, the Board approved a report which contained the following:

> Accordingly the National Science Board considers it proper and desirable for the National Science Foundation to support basic research in the social sciences where such research meets the usual scientific criteria of objectivity, verifiability. and generality.

Strangely enough, however, the Committee which wrote the report went on to say that, "to direct and guide this growth the Committee would recommend the establishment of an office (not a division) of the social sciences." The Board was reluctant to go all the way and recommended Divisional Committee, although the Board said that there should be an advisory committee similar in caliber to the present Divisional Committees. The reason for this strange reservation is not clear to me.

Nevertheless, the growth in support of the social sciences has risen rather spectacularly from $300,000 in 1957 to $9 million in 1965, and the growth should and will continue.

Undoubtedly, with the passage of acts establishing a National Arts Foundation and a National Humanities Foundation the position of the social sciences in the National Science Foundation will become more

easily defensible since they will not be covered by any other organization (e.g., a National Social Science Foundation).

7. The budget of NSF has increased from about $15 to $480 million, and some witnesses have suggested that it become as large as $1 billion in the foreseeable future. With this tremendous growth, is it in the best interest of science to maintain this dual (Board and Director authority over NSF, or would it perhaps be better to have the Director solely responsible for the management and operation of the Foundation, and have the Board serve in an advisory capacity to the Director (a National Science Advisory Board)?

7. Stated more bluntly, but perhaps more incisively, this question could be "who is going to run the program of the National Science Foundation? The Board of the National Science Foundation, or the Office of Science and Technology (the President's Scientific Advisory Committee)?" This has been a problem which has been debated in one form or the other at great length by the Board. Perhaps it would be wise to outline the history of events up to the reasking of this question.

It should be realized that the Congress, by establishing the National Science Foundation, created a new method for Government operations. The original suggestions for the act came from officers of foundations and universities, and every attempt was made to provide a foundation which would follow the same kind of operation, with a board of trustees, a president, and an operating staff. This is quite different from the normal Government operating agencies which must report to the administration and to the Congress. When finally established, the National Science Foundation was different from other agencies in that there is in fact a third source of policy guidance and control, the National Science Foundation Board.

It will be recalled that in the first version of the act the Director was to be appointed by the Board (customary university practice). To this, President Truman objected by saying that the Director must be appointed by the President and be responsible to him, and not to the Board. [This problem is discussed more completely in a Board report "Report of the Ad Hoc Committee on the Relationship Between the Board and the Director" of December 1, 1958—The Middlebush Report.]

Eventually, the act was passed providing that the Director should be appointed by the President, with the approval of the Senate.

This act then created a strange arrangement in which the staff of the Foundation reported to the Director, the Director reported to the President, but the Board was responsible for policy and programs without having its own staff. There were thus three groups which had some measure of veto power over the activities of the Foundation; the Board, the executive branch, and the Congress. As long as all three groups are in favor of a given policy or project, there is no problem. So far, there has never been a confrontation in which one of the three felt it necessary to use the power of veto. However, the opportunity for conflict has always been there.

The Board spent a great deal of time in 1961 and 1962 discussing how well this relationship had worked. Dr. Baker, as chairman of an ad hoc Committee on the Organization of Government for Science and Technology, produced a report on the matter which said in essence that continued successful operation was possible.

On March 15, 1962, the Board was informed that a reorganization plan was being written for submission to the Congress "which will among other things create an Office of Science and Technology in the Executive Office of the President. This act was expected to do several things. It would transfer the evaluation function (of the Board) to the new Office and the authority to develop and encourage a national policy for basic research and education in the sciences. Other changes would make the Director a voting member of the Board, and have the divisional committees report to the Director rather than jointly to the Director and the Board." [1] There were other proposals which were intended to reduce the size of the Board and to change the term of the Director. All of these proposals were discussed. Some of which met with approval and others with strong disapproval.

This matter was discussed in executive session on March 15, 1962, and it was agreed that it would be unfortunate to reduce the size of the Board, change the term of office, or to reduce the Board to an advisory board only.

At one point in the review the Chairman, Dr. Bronk, summed things up by saying:

> I consider the relationship between the Director and the Board to have been most satisfactory—there have been no unresolved matters between them. By being responsible for the formulation of policy and decisions on the Foundations programs and budgets, the Board members have felt that they have rendered a considerable service to science in this country. *These same members would probably not have given so freely of their time and effort if they had been serving only in an advisory capacity.* [Italic supplied.]

As a matter of fact, Dr. Bronk felt the organization of the Foundation might well serve as a pattern for other Government agencies.

To complete the history, it should only be noted that the most recent Reorganization Act (1965) abolished the statutory requirement for the divisional committees. Since they did not report to the Board, the Board did not vote on the desirability of this change.

Now the question, should the Board become advisory only, must be faced again. My own personal opinion is that the Board should not be reduced to the status of an advisory board only. However, to discharge its functions it is going to have to work harder and more efficiently than it has been able to do in the past few years. It has reorganized itself, but it will require some competent full-time help reporting to the Board through its committee chairman to dig out the necessary facts and to help the committees formulate policy. The Board should be given a few more years to see if it can satisfactorily live up to the high expectations its founders had, and to see if it can discharge its duties. If it cannot, obviously a new arrangement, with congressional

---

[1] From minutes of NSB meeting 77, May 17, 1962:

(1) To the new Office will be transferred from the Foundation as follows: (*a*) the first part of sec. 3(a)(6) of the NSF Act as amended, namely: "to evaluate scientific research programs undertaken by agencies of the Federal Government * * *"; and (*b*) so much of the authority of sec. 3(a)(1) of the act "to develop and encourage the pursuit of a national policy for the promotion of basic research and education of a national policy for the promotion of basic research and education in the sciences" as will enable the Director of the new Office "to advise and assist the President in achieving coordinated Federal policies for the promotion of basic research and education in the sciences."

(2) The Director will become a full voting member of the Board.

(3) The Executive Committee of the Board will be composed of five voting members, four elected from the Board and the Director of the Foundation who will serve as Chairman.

(4) The divisional committees will report to the Director rather than to the Board and the Director.

approval, must be found. That arrangement would probably reduce the Board to an advisory one.

8. What is the Board's fundamental policy with respect to NSF fellowships and grants to universities and colleges? Is your policy aimed primarily at supporting scientific research on the campus, and secondarily at the education of students and the training of science teachers; or is it vice versa?

8. The Board's fundamental policy with respect to NSF fellowships and grants to universities and colleges derives from the Foundation's statutory mandate to initiate and support basic research and scientific research potential in all fields of science (including engineering). The operation of this policy (which has never been further codified) is characterized by the following principles: (1) awards will be made to support the work of individuals of high merit to enable them to undertake activities of high quality; (2) research is enhanced when it also provides training for graduate students, recent postdoctorals, etc.; (3) if it is to be fully effective, graduate education must be associated with high-quality research; (4) research and education are closely intertwined on university campuses and should not be thought of as competitive activities. Having said this, however, let me draw specific attention to the fact that the Foundation's teacher training activities, its course content improvement work and all the rest of its science education programs are based in the last analysis on the conviction that, by making our science education better we will thereby assure (in the long run) more and better research.

I do not think it would be a profitable exercise to rank the research and education responsibilities of the Foundation, especially as they apply to university and college activities in the pursuit of basic research. Both activities must be viewed as being of the highest priority and of equal status in fulfilling the mission assigned to the Foundation by Congress.

9. What is the Board's view regarding the stationary level of the NSF staff over several years when its own funding and that of Government has sharply grown? Is the staff assistance provided for the Board satisfactory?

9. The Board has never concerned itself particularly with the number of personnel and the grade level of the Foundation's staff, assuming that they were of an administrative nature and therefore the responsibility of the Director. However, it is quite evident that at the highest levels (the only ones with whom I came in contact), many are extremely hard pressed and probably overworked.

The secretariat of the Board is quite satisfactory.

However, it is my opinion that if the Board is to really make studies on which policy can be based, its own staff must be considerably augmented. This augmentation must be with full-time people whose primary job is to serve the Board in this capacity.

10. In what areas should NSF exercise its existing authority further? What new roles do you foresee for the Foundation over the next 10 years and what new authority seems warranted, as for example in areas of applied research and engineering?

10. I think that there are a number of areas in which the National Science Foundation should exercise its existing authority further. These are in the area of the relationship of science and engineering

to problems which fall in the public domain. To conduct design and engineering studies on unique systems which do not come under the purview of private industry—e.g., weather modification, transportation, water retrieval, et cetera. However, it is doubtful that these will be undertaken unless the Foundation is specifically directed to do so by the Congress.

11. Could you give examples of policy guidance developed by the Board—especially to distinguish between its passive role of endorsing NSF staff proposals and an active role of taking initiative?

11. Two most recent examples are the development of policies by Board Committees which were subsequently approved by full Board as follows:

(*a*) "The Role of the National Science Foundation in Support of Research in Ground-based Astronomy" proposed by Committee III and approved by the Board at its 100th meeting (May 1965) is as follows:

The hope of understanding of the universe in which man finds himself is one of the most exciting prospects of our time. Man yearns to understand how the universe came into being, what forces and phenomena resulted in the dispersion of matter which has been revealed to date. How old is it? How large is it? How far are the starts? Of what are they made? What is the source of the energy which comes to us? These are age-old questions, the answers to which seem potentially available as a consequence of intensified efforts using the refined techniques of modern astronomy. For many years to come, adventures in cosmology and astrophysics will exercise enormous intellectual appeal. The continuing acquisition of increasingly detailed and sophisticated astronomical information will provide scientists and laymen opportunity to develop some understanding of the universe in which he lives. In our view, such understanding more than justifies the effort and costs essential to its attainment.

The Whitford report.—In preparation for this effort a panel of astronomers, chaired by Dr. A. E. Whitford, issued a report, through the Committee on Science and Public Policy of the National Academy of Sciences, which contains a series of recommendations for the addition of new optical and radio telescopes to the national armamentarium. This report limited itself to a timetable for the acquisition of new telescopes, of various sizes, while ignoring the costs of their operation, the costs of current programs in astronomy and their possible expansion, development of new auxiliary equipment for conventional telescopes, the special requirements for observations of the solar system by the National Aeronautics and Space Administration, solar astronomy, and the possible elaboration of space-based astronomy. Insofar as this Committee, and other inquiring groups have been able to ascertain, the response of the public and scientific world to the report has ranged from receptive to enthusiastic and in general has been very favorable.

Interagency assessment of the Whitford report.—As a step toward evaluation of the specific recommendations of the Academy report, the Director of the Office of Science and Technology requested the Director of the Foundation to establish an ad hoc group of representatives of those Federal agencies with an interest in the support of ground-based astronomy for the purpose of assessing the Whitford report. This Interagency Committee was chaired by Dr. Geoffrey Keller. Dr. Keller's committee examined the specific recommendations of the Whitford report and accepted their validity as a basis for planning. They attempted an assessment and anlysis of the full costs which would be incurred by the various Federal agencies over the next decade if all the recommendations in the Whitford report were to be implemented. Further, the Interagency Committee estimated the cost of continuing all federally supported programs for research in astronomy already underway with particular attention to the needs of astronomers located at universities which are not directly associated with major astronomical observatories. Thus, the Interagency Committee attempted an assessment of the totality of "small science" in astronomy as well as the new costs of "big science" as recommended by the Whitford panel.

Appendix I summarizes the total expenditures for ground-based astronomy which the NSF might expend over 12 fiscal years as projected by the Division of Mathematical and Physical Sciences staff from the interagency report.

Appendix II presents a tentative total Federal budget for the support of ground-based astronomy as prepared by the Interagency Committee.

Appendix III presents a tentative detailed budget for the total support of ground-based astronomy by the Foundation, based upon the allocations and projections of this Interagency Committee.

Questionnaire to the community of astronomers.—In an attempt to establish the validity of the initial recommendations of the Whitford report, Committee III sampled the community of astronomers by posing a series of questions to a selected group of 17 astronomers currently supported by the Foundation. The results of this inquiry have satisfied the Committee that the recommendations of the Whitford report are sound in that they project a national program which is within the capacity of the American community of astronomers and which, if implemented, would provide for a vigorous national program while not satisfying all of the requests of any segment of this community.

RECOMMENDATIONS TO THE BOARD FROM COMMITTEE III

A. *On the implementation of the Whitford and interagency reports.*—After examination of the Whitford report, the report of the Interagency Committee, and replies of practicing astronomers to its own questionnaire, Committee III has studied the plans of the Division of Mathematical and Physical Sciences of the Foundation for the support of ground-based astronomy over the next decade as summarized in appendix I which is derived from documents NSB/C–III–65–12:11–16, appendix B (auxiliary table VIII, actual and planned funding by NSF for various budget categories). Committee III considers these projections to be reasonable and appropriate as goals toward which the Foundation should strive.

Accordingly, Committee III endorses the general plans of the MPS Division with respect to ground-based astronomy and recommendts their approval.

Such approval must be accompanied by the caveat which the Director provided to the Director of the Office of Science and Technology concerning the assessment of the ad hoc interagency group:

"* * * as the Foundation develops its specific future plans for this field, it must, of course, give equally specific attention to the needs of other sciences. With this reservation, however, I believe that the Foundation's role should be along the lines suggested in the assessment, subject of course to the availability of funds for this and all other activities for which we are responsible."

(*a*) It should be noted that the support of university-based research in astronomy as outlined in the MPS plan provides for growth at about 15 percent per year. The funds in this plan which relate to university-based astronomy research shall be considered as flexible and shall be used to facilitate the most appropriate expansion of the Nation's capabilities in basic ground-based astronomical research as circumstances dictate.

(*b*) In seeking appropriations to implement the overall plan, major capital equipment items should be presented as budgetary line items in order (1) to assure visibility to Congressional Appropriations Committees and (2) to minimize competition between such requests and the Foundation's continuing needs for its normal appropriations.

(*c*) Appropriations for funding minor capital equipment should be achieved from the general research projects appropriation to the Foundation and should be defended and justified in competitive fashion as in all other fields of science in the manner normal to NSF operation.

(*d*) Each item of major capital equipment should be supported by the Foundation only after its provision has been given specific scientific justification and the Foundation is assured that a highly qualified scientific user's group will assure competent use and operation of such a facility.

(*e*) In the event that appropriations are insufficient to fund all requested new major facilities, priority among them should be given to those which provide new capabilities beyond those of existing instrumentation.

(*f*) The annual award in support of any major astronomical facility may provide for the necessary operating and maintenance costs thereof, plus additional funds required for the specific projects proposed by the staff of said facility which would permit use, by that staff, of a reasonable fraction of the time on that facility. The remainder of costs should be funded by

a combination of direct support to the facility and grants going directly to the institutions of guest scientists based elsewhere than at the facility.

In general, the latter grants will support the research programs of this group of scientists both at their home bases and at the facility.

B. *On the concept of a "principal Federal agent" for a scientific discipline.*— The progress of certain fields of science is closely related to the successful accomplishment of the specific missions of certain Federal agencies. Among such instances may be noted high energy physics (AEC), materials research (ARPA), health related research (NIH), and space-based astronomy (NASA). This has led, rather naturally, to the assumption by these agencies of responsibility for the welfare of their related scientific fields for which they presently provide the predominant Federal source of funds. The Foundation is also the predominant supporting agency for a series of scientific fields for which no other natural alliance is evident, e.g., taxonomic biology, research in the Antarctic, deep crustal studies, as well as much of mathematics, physics, and chemistry.

Other fields of science have found support from a diversity of Federal agencies, no one of which has assumed, by practice or policy, responsibility for assuring their continuing welfare, e.g., ground-based astronomy and much of chemistry. Under these circumstances, there is danger that the relative vitality of these fields may be jeopardized for lack of a single agency which assumes responsibility for coordination and planned support.

Under the latter circumstances, in order to assure the continuing vitality of each such discipline, it appears appropriate that a specific Federal agency be publicly recognized as the principal Federal agent for that area of science. It is implicit in the role of a principal Federal agent that (1) the agency staff must include individuals who are well versed in the field, its techniques, accomplishments, and aspirations; (2) the principal agent accepts responsibility for a major share of Federal financing of that field; (3) the agent and its staff must be vigilant with respect to the continuing health of the national program with regard to that field of science and should, as circumstances require, undertake to elicit and stimulate support from other Federal and private agencies for those aspects of the field which can appropriately be supported within the recognized missions of those agencies; (4) the principal agent should assume responsibility for preparation of an annual report to the Office of Science and Technology and to the Congress on the progress of the area of science for which it has accepted responsibility and on the total financial support for that field from all branches of the Federal establishment and from the principal non-Federal sources.

Responsibility for the prime support of astronomy is entirely compatible with the broad mission of the National Science Foundation—the health, vigor, and development of the total national scientific enterprise. This role was essentially accepted, pari passu, when the Foundation undertook support of NRAO and of KPNO.

For many years to come, ground-based astronomy will remain an important and exciting frontier of science. Although space-based astronomy will introduce many new techniques, such developments predictably will create additional, rather than lesser, interests in and need for research in ground-based astronomy. Although NASA will continue to have great involvement with space-based astronomy, no Federal agency other than the Foundation is a natural base for support of ground-based astronomy.

Accordingly, the committee recommends that the National Science Foundation should offer to assume the role of principal Federal agent for ground-based astronomy.

APPENDIX I

NSF expenditures for astronomy, fiscal years 1965–76

	Millions
A. Acquisition of Whitford Facilities, Operation of Whitford Facilities	$224.8
B. Kitt Peak National Observatory	48.7
C. Cerro Tololo Inter-American Observatory	20.3
D. Arecibo	13.3
E. National Radio Astronomy Observatory	81.1
F. University based—General	141.2
Total	529.4

APPENDIX II

Summary of recommendations by interagency group

[In millions]

	Whitford report recommendations (A)	Plan proposed in this assessment: Funds to build and operate W.R. recommended facilities (from table I) (B)	Plan proposed in this assessment: Funds for support of all activities in ground-based astronomy (from table VII) (C)
Fiscal year:			
1965 (actual)		$7.6	$25.5
1966 (planned)		24.0	33.9
1967	$12.4	23.7	57.6
1968	19.4	25.9	63.1
1969	24.0	40.1	80.3
1970	26.1	31.5	75.2
1971	26.2	26.1	73.7
1972-76	115.9	118.5	430.4
Total	224.1	[1] 297.4	839.7

[1] This estimate does not include the cost of supporting the scientists who would, as visitors, use the larger telescopes listed in table I. It is anticipated that all the instruments in the category optical, large telescopes, a few in the category optical, intermediate-sized telescopes, and, among the radio telescopes, the high resolution array, the 8-antenna mobile array, and the 2,300-foot steerable telescopes would be available for use by visitors approximately half of their operating time. It is estimated that the Federal funds for support of these users, including their students, special equipment, travel, and other expenses associated with the part of their research efforts based on use of the large telescopes as visitors would cost, over the same period, between $6,000,000 and $8,000,000. This user cost has already been included, however, in the estimates in the right-hand column.

AUXILIARY TABLE VIII.—*Actual and planned funding by NSF for various budget categories, itemized by facility or other purpose*

[In millions of dollars]

Funding agency and purpose	Actual, fiscal year 1965	Planned, fiscal year 1966	1967	1968	1969	1970	1971	1972–76	Total
NSF (KPNO):									
150-inch telescope [1]	1.9		7.4						9.3
Operation [1]								(1.8)	(1.8)
84-inch telescope							2.6		2.6
Operation								(.2)	(.2)
Reflecting coronagraph				0.3					.3
Operation								(.2)	(.2)
Feasibility study for largest feasible reflector [2]			.3	.3	0.3	0.3	.3		1.5
Other ground-based capital and operation	2.3	2.8	3.6	3.3	4.2	4.2	4.5	23.3	48.1
Total KPNO, ground based	4.2	2.8	11.3	3.9	4.5	4.5	7.4	25.5	64.1
Space astronomy program	2.7	3.5	3.7	3.9	4.1	4.2	4.5	25.5	52.2
Total KPNO	6.9	6.3	15.0	7.8	8.6	8.7	11.9	51.0	116.2
NSF (CTIO):									
200-inch telescope [3]				2.0	21.0				23.0
Operation [3]								(0)	(0)
Other capital and operation	1.3	.9	1.8	1.5	1.5	1.6	1.7	10.0	20.3
Total CTIO	1.3	.9	1.8	3.5	22.5	1.6	1.7	10.0	43.3

See footnotes at end of table, pp. 1339, 1340.

AUXILIARY TABLE VIII.—*Actual and planned funding by NSF for various budget categories, itemized by facility or other purpose*—Continued

[In millions of dollars]

Funding agency and purpose	Actual, fiscal year 1965	Planned, fiscal year 1966	1967	1968	1969	1970	1971	1972–76	Total
NSF (NRAO):									
Very-large high-resolution array:									
Design and construction [4]	0	.2	2.0	12.0	10.0	8.0	7.8	0	40.0
Operation [4]					(.4)	(2.8)	(4.8)	(38.4)	(46.4)
Very large paraboloid: Feasibility and engineering study [5]	0	.1	.2	.7					1.0
Other, capital and operation	3.3	4.8	5.3	5.8	5.9	6.5	7.0	42.5	81.1
Total NRAO	3.3	5.1	7.5	18.5	16.3	17.3	19.6	80.9	168.5

NSF, total	14.4	16.6	37.4	40.9	56.7	50.7	47.4	265.3	529.4

NOTES

[1] Maintenance and operation costs estimated at $150,000 per year; auxiliary instrumentation estimated at $200,000 per year for total operating cost of $350,000 per year starting 1972.

[2] No construction or operating costs included.

[3] Total operating costs start 1979.

[4] For overall annual operating rates of smaller radio astronomy facilities (excluding users' costs) the figure of 25 percent of capital cost has been used. In the case of the very large array it has been assumed that the elements of the array will come into operation gradually over a 10-year period, and that the operating costs will increase accordingly over this period. Maintenance cost of such an instrument will certainly increase with the number of elements, but to the extent that it is used as a single observing system, the number of scientists which will be able to use it in the course of a year will probably not increase as rapidly. With this in mind the operating cost has been calculated at a rate of 20 percent of capital cost instead of 25 percent. To a considerable extent the quantity and sophistication of the data which can be obtained from the array will depend on the level of operating support which is provided.

[5] No construction funds have been included in this plan pending the completion of the feasibility study. Study cost schedule is that suggested by NRAO.

[6] Includes both Government in-house efforts shared by universities and university instruments. It is hoped that the cost of NASA- and NSF-supported purchases will be shared to some extent by the recipient institutions but it is difficult to estimate the amount of such contributions. This item will also provide for some telescopes smaller than 36 inches (the definition of this class in the Whitford report). The total number of telescopes provided will depend on size, but assuming an average cost of $500,000, some 17 or 18 could be supported, or more if cost is shared by the institutions.

[7] These 8 dishes will be added to the 2 existing 90-foot dishes currently being used as an interferometer. The fiscal year 1965 funding provides for 1 additional 130-foot dish, the fiscal year 1968 funding is intended to provide 3 more, and the fiscal year 1970 funding the remaining 4. Current support is from ONR at $250,000 per year. The operating funds indicated in the table are intended to cover increased operating needs as the additional dishes come into operation. Some of this additional support may be provided by ONR. For the reasons given in note 4, the additional operating cost has been calculated at 20 percent of the additional capital cost.

[8] Total operating cost (not including users' costs) estimated at $500,000 per year.

[9] It has been tentatively agreed that NSF will share the cost of operating this installation, particularly with regard to the radio astronomy research done at this station, with DOD.

(Continued at foot of p. 1340.)

(*b*) "Use of Digital Computers in Universities and Colleges," proposed by Committee I and adopted by the Board at its 100th meeting (May 1965) is as follows:

Committee I has considered the role of the National Science Foundation in the oncoming activities in the Nation's colleges and universities based on the use of digital computers. Most of these activities are presently supported by the Federal Government. The need for these machines is expected to continue to grow so fast that the costs, and supporting elements, such as skilled manpower, Federal administration, etc. involved in their use may soon become major items in the resources available for national science and engineering training and research. The shape of this climbing curve of usage was foreseen by the Director of the National Science Foundation, Dr. Alan T. Waterman, when he requested the National Academy of Sciences-National Research Council in June of 1962 to undertake a broad study of the needs of colleges and and universities for such computers. This study, being performed by a distinguished group of experts, has not yet been completed, although it may appear in the coming summer; it has been surveyed by the Committee on Science and Public Policy of the National Academy of Sciences. Committee I is pleased to have been able to review a preliminary draft of this report. The Committee has benefited by regarding certain dimensions quite firmly established by the report, such as the 45-percent annual growth curve of the capital cost (i.e., "purchase value") of computers presently at universities and colleges. This has led to a present figure of about one-quarter billion dollars capital investment without discount or depreciation. Also, the annual staff costs are apparently one-fifth or one-quarter of this overall figure and are rising rapidly. Indeed, the aforementioned Committee on Uses of Computers, chaired by Dr. J. Barkley Rosser of the University of Wisconsin, estimates that the total annual costs, based on just equivalent annual rental corresponding to the capital value mentioned earlier, are already $137 million and will rise by 1968 to about $236 million. When it is recalled that this figure would perhaps exceed our total NSF basic research project grant figure and, indeed, compares with half the total Foundation budget, we can appreciate what this university and college computer activity represents. The important thing is that although the largest part of this usage cost is already devoted to scientific and engineering research along the lines of the Foundation's major mission, these costs reflect only the barest beginnings of the very large role that digital machines will have in education itself, and in many parts of science and technology in universities which are now barely involved.

Beyond these dimensional features, Committee I has also had in mind the national policies reflected in the President's report to the Congress of March 2, 1965. In this, the Bureau of the Budget has carried out a study of use of automatic data processing machinery within the Government itself. The history of this usage is also instructive for the considerations of the National Science Board. The report asserts that in 1954 the Government had used a total of 10 computers and that today, excluding military operations and security uses, it employs directly 1,800 computers at a cost of about $1 billion annually. It is further estimated that 3,600 more computers are used in special security and military operations, including those of private contractors used on a cost-reimbursement basis. It was believed that this represents about $3 billion more in annual cost. Now, evidently an operation of this importance and magnitude will attract much attention administratively throughout the Government, and it is therefore particularly important that complex and unconventional use of these equipments, such as may be expected in universities and colleges, be managed so that undue restraints arising from the massive costs of the total Federal program will be avoided. The President's message, for instance, accents questions of centralized computing centers for more efficient utilization of equipment, problems of purchase versus rental, standardization of equipment (and, hopefully, of software—programing facilities, etc.) and so on. The study and the Presi-

[10] Operation costs of many existing university radio telescopes appear below in the item for "Support of other basic research at universities."

[11] Numbers in this line have been adjusted to reflect-pe a 15rcent increase annually starting in 1967. Costs of support of balloon astronomy are included.

[12] The 1965 and 1966 figures exclude astronomy basic research funds allocated to support rocket astronomy research at the E. O. Hulburt Center at NRL. It should be remarked that the method of obtaining this total reflects the assumption that the support of basic research at universities, including the users of large facilities (calculated to increase at 15 percent per year) should not be required to carry the cost of operating large telescopes.

dent's message avoid the temptation of proposing a separate central office for the procurement and utilization of electronic computers and, indeed, emphasize the responsibility of various agencies to control their own costs and operations. Basic in all these considerations is the compelling requirement for more trained personnel and sophisticated operators and users. This educational program alone requires and deserves a major effort.

Cognizant of these various factors, but impelled chiefly by the great opportunities in the use of electronic computers for the advance of human knowledge and, especially, by the chance they offer for the liberation of creative minds from the demands of routine data and pattern analysis, Committee I forwards the following position:

1. Automatic information processing machinery, particularly electronic digital computers, are essential aids to modern research in science and engineering. Such facilities will probably become important in the methodology of education as well (through information retrieval, display, bibliographic function, etc.). Accordingly, universities and colleges (as well as other institutions which sponsor research and learning in science and technology) should have appropriate computing facilities. The need for quantity and quality of such facilities should be demonstrated on an analogous base of merit and opportunity as has been applied for Federal support of research and education in science and engineering in these institutions.

2. The National Science Foundation should assume a general responsibility in the Government for monitoring and encouraging appropriate development of these facilities and their use in universities and colleges. This policy does not specify the proportion of total financial support to come from the National Science Foundation, since other agencies may have special reasons for very extensive support in particular situations and, in any case, the well-known national policy of diversity for research funding applies in this case. However, in terms of its statutory mission to assure the vigor and progress of basic research and education in the sciences, the NSF should undertake to see that automatic data processing facilities become extensively and increasingly available to American institutions of higher learning.

3. Accordingly, in collaboration with the Director and staff of the NSF, Committee I has proposed that certain task forces be activated promptly to gather information for preparing to submit to the National Science Board, various policies which would activate the aforementioned role of the National Science Foundation.

4. Particularly, these task forces include—

(*a*) A group having interagency associations which will seek to identify the current university computer support in terms of the Federal agencies and fundings;

(*b*) A group which will study the accounting and fiscal aspects of controls relating to computer support in universities and colleges. This group, which will be primarily comptroller officials of various agencies, will consider such problems as the requirement that all academic users, sponsored or nonsponsored, be charged at the same rate. It will be also concerned with the rent-versus-buy questions and other elements of the Federal policy.

(*c*) A group of experts in computer systems design and usage, from Government, universities, and industry (perhaps not the computer industry), who will assess the opportunities for organizing facilities for academic use. This is so that the many options can become known to the many institutions which may be acquiring facilities. Thus, centralization, input-output stations, graphic displays, etc., should be surveyed, and recommendations made for the best overall (but flexible) approaches.

RUFUS E. CLEMENT.
KATHARINE E. MCBRIDE.
EDWARD J. MCSHANE.
ROBERT S. MORISON,
Vice Chairman.
WILLIAM W. RUBEY.
EDWARD L. TATUM.
ERIC A. WALKER.
W. O. BAKER,
Chairman.

12. Are the goals of the Gilliland reports still valid? How is the NSF fulfilling its responsibilities to meeting these goals?

12. The Gilliland Panel recommended the following goals:

1. To increase the number of doctor's degrees awarded each year in engineering, mathematics, and the physical sciences (EMP fields) to reach 7,500 in 1970. Percentage increases are intended to be greater in engineering than in other EMP fields.
2. Increase the number of students who complete a full year of graduate training in the EMP fields to reach 30,000 during 1970.
3. Encourage the strengthening of existing centers of excellence in the EMP fields and develop new centers of educational excellence.
4. Promote wider geographic distribution of centers of educational excellence.

It is my opinion that these goals are still valid and will remain valid for at least another 5 years.

The National Science Foundation is moving to fulfill its responsibilities in reaching these goals. Perhaps the money has not been sufficient to take the step forward that many educators believe is necessary. Nevertheless, in fiscal year 1964 approximately 1,200 traineeships were established in engineering. In fiscal year 1965 approximately 2,800 traineeships were granted in engineering, mathematics, and physics. This number is lower than it should have been. Of this 2,800, there were 1,800 in engineering and the others were in mathematics and physics. Unfortunately, the 1,800 in engineering allowed about 900 of the original 1,200 engineering trainees to continue into their second year, and the number of new first-year traineeships was reduced from 1,200 to about 700. This produced considerable unhappiness among engineering educators. However, the problem is one that only money can solve.

13. Are too many Federal agencies today involved in supporting basic science grants and science education? Might not the Foundation assume a more central, or perhaps an exclusive role in this regard?

13. It is my own personal opinion that this is so; that many of the things that are done under other agencies could well be done under the National Science Foundation. However, these could not be done without an increase in the numbers of the National Science Foundation staff and a strengthening of the National Science Foundation Board.

14. What is the Board's policy with respect to geographical dispersal of institutional support? Has there been any effective dispersal? What has the Foundation done in response to the 1960 report of the President's Scientific Advisory Committee which advocated additional centers of academic excellence?

14. The first two-thirds of the Foundation's operational history was concerned with the establishment of effective programs for identifying highly qualified individuals who might be assisted in undertaking highly meritorious science projects. During this earlier period, geographic factors played a secondary role to such qualitative considerations. In the last third of the Foundation's existence, however, institutional support has taken on added importance and geographic dispersal has been recognized as a vital element in such support. The Foundation's institutional base grants program with the "tapered

formula" attached to such support, while it is not directly tied to geography, has tended to insure a spreading of institutional support.

The Board has over the years become increasingly concerned about the need for recognizing geographic factors in providing institutional support. Institutional support activities, including the science development program, have been initiated by the Foundation with Board encouragement and approval. The science development program, which now has made major institutional strengthening grants to 10 universities in widely dispersed areas, is in direct response to the 1960 recommendation of the President's Science Advisory Committee.

The Board has established a special committee of its members to provide continuing review of the science development program. The Board is also considering what other steps can be undertaken to identify and strengthen institutions and departments of high science potential. The Foundation is still in the early stages of these programs, but they should have an important effect in attaining added scientific strength in the different geographical areas of the country. It is too early to claim "effective dispersal" of institutional support, but these newer programs of the Foundation are certainly pointed toward such a goal.

15. A dropout problem exists for students of science and engineering as well as other subjects. What should the NSF do to study the reasons for dropouts in secondary schools and colleges? Should it take a mission interest and actively seek to interest investigators in such studies, or should it wait and hope that some scientists will become interested on their own and submit suitable proposals?

15. I do not regard this as a problem for the National Science Foundation. Although one might say that research in education could come under the aegis of the Board, I believe it would be better done under the Office of Education. Although there might be a science of education, the Office of Education is more likely to give it the proper priority than is the National Science Foundation.

16. Should the Foundation's national laboratories and, for that matter, the large laboratories of other departments, such as the AEC Argonne National Laboratory, be treated as permanent national scientific assets to be indefinitely maintained, or should their continued existence depend upon the current vitality and importance of the fields of science in which they excel? Should they have an indefinite mortgage upon future resources for science? If so, what should be their role as efforts and attention of scientists change to new fields?

16. I do not think so. I do not think that any laboratory should be maintained when the scientific field in which it is interested has dried up. In such instances (and I am not sure that there are any in existence at the present moment), the laboratories should be closed, the programs tied off, the people allowed to seek newer and more exciting projects elsewhere, and if necessary, the physical facilities should be mothballed until there is another need for them.

17. What is your opinion about the proposal that annual funding for NSF-supported basic research be increased by 15 percent annually to accommodate entry of new scientists into independent research and to cover the increased cost of equipment? Do you see graduate schools capable of accommodating a continually growing graduate student

body in the sciences? Can the undergraduate colleges be expected to produce more students each year for graduate study in the sciences?

17. I am in complete agreement that the annual funding for NSF-supported basic research should be increased by 15 percent annually. The Board, as a whole, did discuss this problem and, I believe, are in complete agreement. Moreover, we do feel that the graduate schools will be capable of accommodating a continually growing graduate student body if the necessary fellowships and the necessary basic research funds are forthcoming. Moreover, the undegraduate colleges can be expected to produce more students for graduate study in the sciences, at least until the eighties when there might be a slight reversal. However, this is far in the future and is something which can be better assessed as the time draws near.

18. Exactly how do you make use of the Science Information Exchange?

18. The Science Information Exchange evolved from earlier Government information exchange mechanisms which were originally created to maintain information on current research projects and proposals for research support. These mechanisms were devised, first in the biological and medical sciences, to provide coordination of agency support and avoidance of unnecessary duplication by means of a common file of information which could be called upon by Government science administrators. The earlier mechanisms evolved with the increase in Federal support into a larger, more comprehensive system. Today SIE covers both the life sciences and the physical sciences, and some aspects of the social sciences. It includes information on current projects, research proposals, and in some cases subtasks of larger projects. It incorporates activities in basic research, and some aspects of applied research and development. These data are being provided on a periodic basis, throughout the year, to SIE. Furthermore, it contains within its files, which are now partially computerized, information from both Government and private sources.

The Science Information Exchange is still primarily a tool for Government research administrators to aid in the coordination of Government research support. Agencies place their support activities into the files of SIE, which are collated, organized, and stored for retrieval, and program directors and their equivalents call upon these data for checking related activities when considering requests for research support. The physical, engineering, and social sciences coverage within SIE is a relatively new activity. These data are now being handled in much the same way as the biological data are handled, but the SIE files in these newer areas are not as complete as those in the biological sciences. As the SIE files increase, the total cost of maintenance and operation also increases, but the unit cost, of course, is reduced.

The mechanism of use is relatively simple. A program director requests, by use of descriptors, information out of the SIE file for his use. These descriptors are codes or keys under which the data within the files have been stored for rapid retrieval. The effectiveness of the system is directly dependent upon the types of descriptors used as related to the requirements of the users within the Government agencies. The quality of the response, of course, is also dependent on the completeness of the file and the adequacy of the retrieval

system. The problem of an optimum storage and retrieval system for these data is still under study.

I recent years SIE has been providing information from its files to non-Government requestors, principally scientists and institutions. Thus, a semipublic information service has been developing, and the demand for such service has been increasing. The service is somewhat similar to that provided to program directors, although more limited. A qualified requestor may ask for information on a subject or area of interest and receive information from the system. The costs of such an added service are not fully understood, since at present they are treated as "add ons" to the service now being given to Government agencies. This added function has, of necessity, affected the techniques of storage and retrieval. The relationship of this semipublic service to the Government service is also not completely understood and is under study.

19. What attention has the Board given the statistical and analytical functions of the Foundation for scientific and technical manpower? How would the Board propose to speed up and better adapt the statistical services to the needs of the research and policymaking communities?

19. A recent reorganization of the Foundation's planning activities, including the staff groups responsible for the statistical and analytical functions, has served to focus and emphasize the Foundation's special role in these areas. The Board has reviewed and endorsed this reorganization. The Board, moreover, has had an opportunity to become thoroughly familiar with the character of expanded activities planned for the future in relation to the Foundation's statistical and analytical functions. In addition, a Board committee concerned with long-range planning has been established which we anticipate will provide special guidance for the Foundation's statistical and analytical functions through the identification of its own special needs for information and analyses. The Board's composition is in part representative of the research community as a whole. Many of its members are part of or in close touch with policymaking communities. It can be said, therefore, that the Board is in fact a reasonably effective vehicle for representing to the Foundation the needs of these communities.

The statistical activities of the Foundation cover a broad spectrum of data collection and analyses, from both Government and private sources, covering research, development, economic implications, financing, capitalization, institutional commitment, and manpower dynamics. It is no exaggeration to characterize these activities as providing the United States with the best information of this type in the world. This is not to say that there could not be improvement in this activity, especially in the timeliness and utilization of these data. Recently, important steps have been taken to achieve such improvement. The fuller utilization of data processing equipment will help considerably in speeding the analytical and publication process. This will, in turn, insure improved services to the research and policymaking communities.

Response by Dr. William T. Knox, Chairman, Committee on Scientific and Technical Information, Federal Council for Science and Technology, to Questions of the Subcommittee on Science, Research, and Development

---

1. Section 902 of Public Law 85–864 established a statutory "Science Information Council" to advise the National Science Foundation in relation to its then new Science Information Service function.

(*a*) *What is the relationship of this Council to—*

The Office of Science and Technology (*OST*)?

Committee on Scientific and Technical Information (*COSATI*)?

The President's Science Advisory Committee (*PSAC*)?

Federal Council for Science and Technology (*FCST*)?

National Science Board?

1. (*a*) The Science Information Council has no statutory relation to OST, COSATI, PSAC, FCST, or the National Science Board. It gives advice to the Head, Office of Science Information Service, in the National Science Foundation. The Chairman of the Science Information Council has, for the last several years, attended the annual meetings of the Advisory Committee Chairmen held by the Director of the National Science Foundation. There is no continuing liaison by the Science Information Council with any other Government agency or organization.

(*b*) *In your judgment where should basic statutory responsibility for Federal science information services reside?*

(*b*) In my judgment, each and every Federal department and agency concerned with science and technology should have a basic statutory responsibility for insuring a healthy, effective, information service within its sphere of responsibility. As in the case of other functional areas within science and technology, such as national policies for support of basic research, the Federal overall responsibility resides in the Office of Science and Technology.

(*c*) *How is this currently split between NSF, OST, and the Clearinghouse for Federal Scientific and Technical Information?*

(*c*) The Clearinghouse for Federal Scientific and Technical Information, operated by the Department of Commerce under the National Bureau of Standards, was created, under Public Law 776, to provide a central organization through which the public can obtain copies of scientific and technical reports generated by the Federal Government and its contractors. The Clearinghouse has brought to a single organizational focus, and has made more conspicuous the Government's activities in the physical and engineering sciences. A major Federal operating responsibility for information dissemination is thus being executed by the Department of Commerce.

Neither OST nor NSF have operating responsibilities like the Clearinghouse. The National Science Foundation carries out certain functions in support of scientific and technical information, as outlined in my testimony of July 27. The NSF also has management responsibility for the Science Information Exchange and the National Referral Center. It carries major responsibilities for providing liaison between the Federal Government and the professional scientific and engineering societies. The overall leadership for Federal scientific and technical information activities rests with the Office of Science and Technology, as was intended by Reorganization Plan No. 2 of 1962.

2. Supplementing your testimony of July 27, how will the development of the new Clearinghouse for Federal Scientific and Technical Information, under the National Bureau of Standards, affect the responsibilities of NSF for scientific information dissemination? Will there be duplication? Has the NSF lost one of its original functions?

2. Insofar as the Clearinghouse distributes copies of Federal reports to the general public, its operations do not affect the responsibilities of NSF for scientific information dissemination. NSF has consistently encouraged the establishment of the Clearinghouse under its legislative mandate (title IX, National Defense Education Act of 1958) to provide, or arrange for the provision of, the functions necessary for more effective information dissemination. In 1958, for example, NSF transferred funds to the Department of Commerce to expand its acquisitions of technical reports and to speed the production and expand the coverage of the abstract journal, "U.S. Government Research & Development Reports." During the period 1958–61, NSF also chaired a series of meetings with representatives of Commerce and other Federal agencies producing technical reports which resulted in all agencies agreeing to make their unrestricted, unclassified technical reports available to the Clearinghouse.

3. A new Standard Reference Data System directed by the Bureau of Standards is being developed in order to centralize the collection, evaluation, organization, and distribution of scientific data in all fields.

(*a*) *Is this system to be used by the Bureau of Standards' new Clearinghouse?*

(*b*) *Will it decrease the amount of duplication of scientific information dissemination and storage in other Federal agencies?*

(*c*) *What is the relative role of NSF to the system?*

3. The National Standard Reference Data System (NSRDS), managed by the National Bureau of Standards, is restricted to the critical evaluation of selected numerical data in fields of science and technology. The products of this effort will mainly be printed documents, and these will be distributed through normal channels, including the Clearinghouse. The NSRDS addresses a problem in science and technology that is different from the scientific and technical information problem most commonly discussed. The NSRDS has no relation to the problems of document flow in science and technology, except to the extent that research and development will be made more efficient by the NSRDS, and therefore the amount of duplicative research and thereby duplicative documentation may be less. The NSF has no special relation to the NSRDS, although NSF endorsed the idea of the NSRDS when it was presented to COSATI.

4. A PSAC report of 1958 called for a unified, efficient and comprehensive scientific information service with NSF playing a coordinating role. In a January 1959 letter, and in Executive Order 10807 of March 1959, the President asked NSF to assume responsibility for a Federal coordinated plan. Does the transfer of coordinating responsibility to OST in 1964 and the present OST leadership reflect inability of NSF to carry out its assignment?

4. As pointed out in Dr. Hornig's testimony before your committee:

In the mid-1950's the rapidly expanding research and development activities of the many Federal agencies and the growing potential of science and technology to contribute to the Government's programs and policies gave rise to increasing concern over the lack of central consideration of the many ways in which science and technology interact within the governmental structure. It was finally recognized that a major organizational innovation was required, and that the function of central coordination and policy formulation for research and development could be carried out only at the highest level of Government—in the Office of the President. It was further recognized that Presidential leadership for this purpose required special staff support.

Also from Dr. Hornig's testimony:

In recognition that developing science policies affecting several agencies, and evaluating agency programs, can only be performed at a higher level. Reorganization Plan No. 2 was based on a transfer of two functions from the National Science Foundation to the Office of Science and Technology.

The present OST leadership in the field of scientific information is only one of the areas in science and technology in which the formulation of overall Federal plans and evaluation of agency programs is being carried out within the Executive Office of the President.

5. Further supplementing your statement, could you please describe in greater depth the role of the Science Information Service of the Foundation? Do you see changes in this role in the future?

5. The role of the Science Information Service within the National Science Foundation is more properly a matter for comment by the Director of NSF. As indicated in my testimony, however, a special task group from COSATI is devoting considerable attention to the creation of a permanent Federal mechanism for insuring the effective, efficient management of the Federal information network, and insuring its relation to the non-Government parts of the national information network. The National Science Foundation would be seriously considered as a part of the mechanism for insuring the development of an effective and efficient national information network, perhaps in an analogous way to the manner in which it assists OST in the development of national policies for support of basic research in the sciences.

6. Details of a national network of information centers was first proposed by the Crawford report to FCST in May 1962. A similar concept was proposed by Senator Hubert Humphrey. What has been the disposition of those proposals and how are present COSATI concepts related to the Crawford plan?

6. Plans for national networks of information systems or for centralized national information centers have been proposed by a number of individuals. The major plans have been critically analyzed by the COSATI task group on national system(s) and the System Development Corp. The present task group concept for a national network of information systems, with a centralized mechanism for

coordination and guidance, is a logical outgrowth of the excellent proposals put forth in the past. The gaining, over the past few years, of better understanding of the existing national complex of information services, and the specific opportunities for improving its operation have enabled the COSATI task group to select from the previous plans those parts which appear, in the light of today's evidence, to be valuable and permanent.

7. It has been suggested that NSF should have a more important function in COSATI than its other members because it does perform basic research and education functions from which information transfer becomes important. As Chairman of COSATI, what is your view?

7. The National Science Foundation has on occasion sponsored special studies of a broad character, in response both to its own evaluation of national needs and to suggestions by COSATI. NSF is a logical candidate for sponsoring and administering such programs because of its position as an agency which does not operate a specific information service, and because of its broad, permissive legislative authority. It is likely that in the future NSF will be asked to continue to fund special projects of a broad, interagency interest. A number of other agencies represented on COSATI also support a substantial amount of basic and applied research in the information sciences, and education and training activities. The proportion of total Federal R. & D. in information sciences supported by NSF is about 8 percent.

8. With respect to the Science Information Exchange operated by the Smithsonian Institution:

(a) Do the other Federal agencies coordinate adequately with SIE?

8. (a) The coordination of Federal agencies with the Science Information Exchange is improving steadily. Remaining problems, as they are identified, are studied and aggressive attempts are made to resolve the problems.

(b) Are SIE's services duplicated by the Clearinghouse in the Bureau of Standards, or by COSATI, or FCST or OST?

(b) SIE services are not duplicated by the Clearinghouse. COSATI, FCST or OST.

(c) What official position has OST or FCST taken regarding the need for and performance of SIE?

(c) Both OST and the Federal Council have endorsed the desirability of a central registry of federally sponsored research projects, and specifically the Science Information Exchange. SIE is becoming increasingly helpful as its registry of research projects undertaken within the Federal laboratories and sponsored by the Federal Government in outside organizations becomes more complete. SIE's files are especially complete in the life sciences area. This is partly due to the longer experience of SIE in the area, and also partly due to the fact that research projects in the life sciences are more usually carried out by an individual investigator or two, which makes the projects easier to classify and record.

The adequacy of the response of SIE to the needs of its users is the subject of a current study being carried out by the Battelle Memorial Institute under contract with the NSF. It is our expectation that this study will allow valuable insights into measures which are being taken to increase the effectiveness of SIE's performance.

(*d*) *With the development of new project reporting forms by DOD and NASA and the strengthening of cooperative relationships between these agencies, including ILSE, what do you believe is the outlook for making SIE a complete central repository of information on ongoing Federal projects in science and technology, including those in Federal laboratories?*

(*d*) The development of new research project reporting forms by DOD and NASA and the strengthening of cooperative relations between these agencies will contribute to the effective management of the agency research and development programs. The Federal Aviation Agency also intends to make use of the DOD–NASA research project report form. As agency reporting of research projects becomes more complete and more easily processable on modern data processing equipment, it also becomes easier for a central research project registery to obtain a complete file of research projects.

(*e*) *Would it be desirable to relieve NSF of fiscal and managerial responsibility for SIE? Should it perhaps be the responsibility of COSATI with an annual assessment made to the separate agencies?*

(*e*) The National Science Foundation was asked to take the managerial and fiscal responsibility for SIE in 1964 as an outgrowth of the continuing difficulties experienced by SIE in obtaining consistent, constructive support for its operations from its interagency governing board. It was decided (and events have confirmed the wisdom of this decision) that single-agency funding would be better managerial practice, and would contribute to a more effective SIE. To relieve NSF of this responsibility and place it on an interagency advisory committee, such as COSATI, would appear inadvisable.

9. What is being done to improve the techniques for the dissemination of scientific information, and our understanding of the actual dynamics of the communication process?

9. A number of research projects are being funded by Federal agencies, especially the National Science Foundation, and by non-government groups to improve techniques for communication of scientific information. These projects range all the way from an individual investigator working on linguistics to large organizations developing computer-based information systems serving an entire scientific discipline. It is expected that there will be increased needs for Federal support of prototype experiments involving real users and real information in real time, and that the data from these large-scale experiments will be useful in the developing plans for a national network of information systems.

10. How does a science teacher from a small undergraduate liberal arts college go about applying for Federal support of specific research and educational projects?

(*a*) *Is there a central organization in Washington currently available to disseminate the names and locations of Federal agencies upon request of these teachers, or must they search for support by coming to Washington themselves?*

(*b*) *Do you believe regional centers should be established to provide this information?*

(*c*) *Or should a Federal Government representative visit individual colleges annually to give current information to science teachers and to identify projects which would be worthy of Federal support?*

10. A science teacher at a small undergraduate liberal arts college should, in my opinion, first go to his college library to obtain information on programs for Federal support of specific research and educational projects. Federal agencies supporting research prepare many brochures detailing the procedures required for applying for Federal support, and describing the areas of study covered by the several programs. I do not believe regional centers are necessary or desirable, nor do I think Federal Government representatives should make a specific visit to colleges to provide information which can be readily obtained from college libraries.

Response by Dr. Thomas F. Bates, Assistant and Science Adviser to the Secretary of the Interior, to Questions of the Subcommittee on Science, Research, and Development

---

1. The bar diagram (fig. 2) which you presented to the committee on July 28 shows total research expenditures of the Department in fiscal 1965 at a level of about $122 million, of which a little over $20 million was by three water resource agencies—reclamation, saline water, and water resources research. Yet budgetwise, water conservation and development is the Department's largest activity. What is the explanation for this seeming imbalance?*

1. The bar diagram referred to does not accurately represent water resources expenditures of the Department, because of the large amount of research in this area done in the U.S. Geological Survey.

The Department of the Interior estimate for water resources research activities programed for fiscal year 1966 is approximately $58 million—about 47 percent of the Department's total research effort. Eight Interior agencies carry on research in 38 of the 45 water research subject subcategories defined in the fiscal year 1966 water resources research program report of the Federal Council for Science and Technology.

Interior's water research activities for fiscal year 1966 are 48 percent greater than in fiscal year 1965 ($39 million), and 93 percent greater than in fiscal year 1964 ($30 million). The increase in 1966 over 1965 is largely in the program of the Office of Saline Water. The Department contemplates continuous program adjustment to maintain its research activities responsive to the needs for dealing with new and more complex water resources problems.

I have attached a tabulation of the water resources research fiscal year 1966 program estimates of the Interior agencies.

2. What is the nature and extent of Interior's program of research in river basin hydrology? Is this an appropriate field for participation by the National Science Foundation?

2. Research in river basin hydrology (as distinguished from construction, development, and management of waterworks) is largely in the province of the Geological Survey. The first phase of water appraisal work includes stream measurements, ground water exploration, and water quality evaluation which defines the characteristics of the water resources in the basin. Further investigation of the basins are needed in most cases to determine the interrelationships between recharge, movement, losses, uses, and changes which may be brought about by alterations in the natural system or by modifications induced by man's activities.

Many scientific and engineering disciplines may be called upon in conducting research on these factors. For example, one of the illumi-

* See p. 602, vol. I.

nating approaches developed by the Geological Survey, involves the use of an advanced analog model in which the interrelations of precipitation, ground water storage, surface runoff, and base flow are modeled electrically.

The National Science Foundation could assist materially in this area by supporting a larger amount of academic research on the natural processes operating in watersheds. Such information is basic to river basin development planning.

3. The recent National Academy of Sciences report on the science of geography recommended additional support for several fields of geography and the creation of two institutes of geographic research with an annual combined budget of about $900,000. Since the Department of the Interior has a geographic program, what should be the relation of the Department and the Foundation in acting upon the NAS recommendations: Should such centers be funded by the Foundation, or the Department, or by non-Government sources? What relevant discussions have you had with the Foundation?

3. The Department of the Interior is a natural center for new research on geography just as it was a natural home for the Geological Survey nearly 100 years ago. The sciences of the crust of the earth have always been basic, but an onrush of man-environment problems in very recent years has resulted in an urgent need now to reexamine and intensify our research in the uses of space and particularly in the interrelations or "systems" phases of man's various natural resource uses.

One of Secretary Udall's many public statements on the new significance of space is in his pamphlet "The Race for Inner Space," page 21:

> * * * the United States has the opportunity to set an example of how to plan the best relationship of human beings to their environment. We should give solemn attention to the matter of developing the optimum man-land ratio—the ratio which would result not only in the highest and best use of the land, but the highest and best development of free men.

The matter of funding institutes of geographic research will, of course, require considerable study particularly since the need is so great and the area of concern so broad that several types of operations are probably necessary. The Foundation might consider a national center for geographic research to strengthen the fundamental research side of the picture, whereas consideration can be given in Interior to organization and funding required for short- and long-range applied research to provide the background for necessary action programs.

These matters have not been discussed with the Foundation.

4. Your testimony also mentioned studies of outdoor recreation. Do you consider this to be scientific research, or is it merely a matter park statistics and administration?

4. Although the effort in outdoor recreation research is small at the present time, there is a need for research on outdoor recreation phenomena which goes well beyond collection of statistics and effecting administration. Specific research in outdoor recreation will concern human resources and social aspects as well as physical resources. Some of the goals are:

(1) Determination of needs for additional outdoor recreation professional personnel.

(2) Determination of needs and preferences of the users of outdoor recreation.

(3) Determination of the effects of outdoor recreation on human behavioral patterns.

(4) Assessment of future outdoor recreation resources and facility needs nationally with projections of requirements to years 1980, 2000, and 2020. Included also will be research on characteristics of recreation resources, their management, and optimum uses.

5. Can you elaborate a little on your reference to the ecological conflict in the Florida Everglades—that is, the increasing use of the canals by the human population and its effect on the national flora and fauna, from palmettos to alligators. What is the nature of the NSF program you mentioned? Does it need to be modified, expanded?

5. The southern portion of the peninsula of Florida receives most of its fresh water by surface drainage from the Lake Okeechobee region. This flow of fresh water southward and outward toward the coasts inhibits the penetration of salt water into the peninsula. Nevertheless, as the coastline is approached changes of salinity in the inland waters do take place and do much to control the plant and wildlife balances in the area. The various types of grasses, the distribution of mahogany, cyprus, and mixed hardwood hammocks, the areas of mangrove swamps, the inland penetration of marine life in the rivers, and the presence and quantity of numerous species of birds, animals, and fish all relate to balances established by the salt-fresh water relationships. These sensitive ecological situations have not been either understood or appreciated, and consequently, until the past few years, little thought was given to them when needs for the human population of the area were considered. As a result canals dug for irrigation and flood control and major roadways have now disrupted much of the southward flow of fresh water; salt water penetration into the Everglades is increasing each year; and the natural balances are being destroyed to the detriment of plants, wildlife, and humans alike.

The NSF program referred to is in the form of a grant to the Pennsylvania State University for research on "Characteristics of Modern Organic Sediments." It involves a study of past and present ecological situations in the Everglades as related to the formation and occurrence of peat in the area. Although the major objectives of the project are geological, the data being obtained are pertinent and necessary for ecological studies also. NSF has supported the study for approximately 5 years, and the grant was recently renewed with $63,400 being allocated for 2 years. The proposal for renewal requested support in the amount of $68,000 for 1 year, and, consequently, the funds supplied will support approximately one-half of the recommended research.

6. Among the technical departments, Interior is one that does not appear to have an extensive basic research program in colleges and universities. How do you obtain the basic research needed for Interior's scientific activities? Should the Foundation support basic research related to your interests? Have scientists of Interior discussed with the NSF staff or its Board or Director this possibility? With what results?

6. Interior has, up to the present, satisfied most of its basic research needs by inhouse effort. In 1965, the effort amounted to $37 million out of a $115 million R. & D. budget. The need for more basic research support from universities has become evident, however, and contract

and grant programs have been initiated in a number of the Bureaus. The new program of the Office of Water Resources Research, involving grants to universities in the 50 States and Puerto Rico, represents a major step forward in Interior-university relationships.

The National Science Foundation, particularly through its earth sciences and biological programs, does support considerable basic research related to the interests of the Department; but this is simply due to the great breadth of interest involved rather than as a result of planning. There have not been formal discussions between Interior and the Director of NSF on NSF support of basic science of interest to Interior.

Through interest in common programs, such as in geology, oceanography, and atmospheric sciences, specific cooperation has been arranged between Interior programs and NSF-supported research. This could be expanded with real benefit to Interior research needs, with probable benefit to NSF interests, and certainly no loss of NSF responsibilities.

7. Secretary Udall's letter of November 12, 1964, which you introduced at the hearing, outlines research programs in water resources and land resources, among others. In this connection, what is the Denver laboratory of Bureau of Reclamation, financed—from research in the following:

(a) Dam design: Is this considered a science, or is it strictly engineering? How are the studies on this subject, as performed at the Denver Laboratory of Bureau of Reclamation, financed—from research funds, from construction funds, or what?

7. (*a*) Dam design, as practiced in the Bureau of Reclamation, is considered to be a science. Research studies on dam design performed in the Bureau's Denver laboratories are financed from nonreimbursable research funds. Specific dam design is financed with construction funds which are reimbursable to the extent that the total project is reimbursable.

(b) Family farm policy: Are the acreage limitation provisions of reclamation law outmoded by corporate farming? What sort of study, scientific or social, is underway or contemplated regarding the applicability today of the legal limitation of 160 acres for which any individual may receive reclamation project water?

(*b*) The large number of privately owned family farms being successfully operated on reclamation projects today, in compliance with the acreage limitations of reclamation law, indicates that these provisions are not outmoded by corporate farming.

There has been a thorough acreage limitation policy study which the Committee on Interior and Insular Affairs of the Senate by resolution requested the Secretary of the Interior to initiate. The committee requested a report setting forth the history of the laws, regulations, and policies of the Federal Government respecting limitations on the delivery of water from Federal projects to lands for irrigation purposes in excess of a specified or limited number of acres in individual or family ownership and other details on the subject. The Secretary was further requested to include in his report statements of the advantages and disadvantages of the acreage limitation policy as presently in effect, and his recommendation for desirable change or modification.

In response to the request contained in the resolution, the Secretary, on June 30, 1964, transmitted to the committee his study entitled "Acreage Limitation Policy." The report has been published as committee print, 88th Congress, 2d session.

(*c*) *Electric power transmission: How much of the current research in extra-high-voltage, long-distance power transmission is being done by Federal agencies? How much by private enterprise? How much by foreign countries?*

(*c*) Research and development by the major power marketing agencies (Bonneville Power Administration and Bureau of Reclamation) amounted to nearly $900,000 for fiscal year 1965 in the field of electric power transmission facilities. The majority of these moneys were spent in the extra-high-voltage field for both alternating current and direct current programs. No report is available on the R. & D. activities of the Tennessee Valley Authority, which is building extra-high-voltage transmission lines.

From an Edison Electric Institute Bulletin of July 1964 the following statistics were given as to research and development work for calendar year 1963:

138 electric utilities R. & D. on 1,831 projects	$53, 180, 000
Edison Energy Institute funds on 32 projects	757, 578
Manufacturers' effort in the power transmission field including generation, transmission, and distribution	97, 560, 000
Total	151, 497, 578

As can be seen, the Interior effort is only a very small part of the private utility and industry segment of research and development of electric power facilities. In addition, the Edison Electric Institute Bulletin does not include that research being conducted by municipalities, public utility districts, and cooperatives, such as work being done by the city of Los Angeles in connection with building an extra-high-voltage direct current transmission lines as one segment of the Pacific Northwest-Pacific Southwest intertie.

No information is available on research in this field by foreign countries, but it could possibly be of the same magnitude or larger than the U.S. effort.

(*d*) *To what extent, if any, are these three subjects proper fields for inquiry by NSF?*

(*d*) Since proper dam design relates directly to basic research in the area of rock mechanics and the mathematics of stress theory, basic research supported by the National Science Foundation in these areas is very important. There is less relationship of NSF areas of concern to the matters of family farm policy and electric power transmission.

8. *How useful has the Department found the Science Information Exchange? Are any changes needed to make it more useful for your purposes?*

8. The Department has found Science Information Exchange highly useful in furnishing information necessary for research management and for advanced planning. All Interior Research projects have been placed in SIE since about January 1964. The following general uses have been made of SIE services:

(1) Cross-communication on research within the Department.

(2) Review of projects already in effect, in Government or university research programs in various fields such as saline water conversion or water research before placing grants or contracts.

(3) Review of all research in a field of science or geographic area (for example, in ecology or in the Arctic).

During the period of 1 year following January 1964, Interior made 165 requests of SIE, totaling 221 different questions. This resulted in the furnishing of over 20,000 notices of research projects to scientists and research administrators.

The SIE under contract to Interior's Office of Water Resources Research has prepared a catalog on current research in water resources, and is preparing a thesaurus of terms for water research.

Although SIE is working to improve input to the system, the services would be more useful if there was more complete coverage of all Government-supported research projects.

9. In respect to communication with other scientific and technical agencies, you testified that informal relationships are best, but that they require a base of formal relations—and that Interior, at least, does not have adequate formal ties to give informal talks significance. Why is this so? Does it imply any special role for the Information Exchange or for NSF?

9. The absence of enough formal ties between NSF and Interior is the direct result, in my opinion, of the insufficiency of funds being allocated to the study and use of our natural resources. The appropriate sections in NSF have only enough funds to support the most basic research proposals. There is little or no chance for NSF to satisfy enough of the basic research needs and have money left over to move far enough toward more mission-oriented research. Similarly, Interior should do more long-range basic research but cannot when there is not enough money to conduct the "short-range" research necessary to accomplish the "missions." Consequently, it appears that the view has been taken in the past that there is not much point in having, for example, an NSF-Interior Committee working on the problem of closing the gaps in research between the two agencies if there are no funds with which to build the bridges.

This situation will exist as long as funds remain scarce and NSF distributes research funds largely on the basis of proposals submitted (see answer to question 12). Nevertheless, I would agree that another approach can be taken; namely, that of setting up formal NSF-Interior committees with the object of evaluating the problems and initiating action leading hopefully to procurement of funds. I believe the present climate in the executive branch and the Congress makes such an operation more realistic now than in past years.

As to implications re a special role for NSF, I would again refer you to the comments in answer to question 12 (and in my testimony) regarding management, not of research, but of research activity within as well as between fields of science and engineering.

10. As a mineralogist, what can you tell us about the prospects of recovering minerals—especially precious minerals—from the sea? Is there need for scientific research in this field? By what agency or agencies?

10. There are reasons for optimism concerning recovery of minerals from the Continental Shelves and ocean bottom. In certain places minerals from the continental masses have been washed into the ocean and have been redeposited in sufficient quantities to warrant exploitation. Diamonds are currently being recovered from such an underwater deposit off the African coast. Norton Sound in Alaska is being examined to determine the possibility of gold recovery. In addition, numerous bottom samples have shown the presence of base metal compounds in significant quantities.

Information concerning the amounts and location of possible undersea mineral deposits is both scanty and sporadic. There is, therefore, a major need for a continuing systematic sampling program of ocean-bottom materials as a part of the national oceanographic effort. Such a program could best be undertaken by the Geological Survey.

There is also the parallel need to develop the technology that will permit commercial extraction and beneficiation of these resources, and this lies within the mission of the Bureau of Mines.

11. Since the Mohole project is a great geological experiment, what has been the role of your Department vis-a-vis the Foundation in the project?

11. Personnel of the Geological Survey have served on committees and task forces assembled for evaluating the Mohole project, investigating its feasibility, and selecting the drilling site.

Geological Survey personnel have participated extensively in some of the experiments under the Mohole project, and provided laboratory services in studies of samples necessary to the project.

12. From your standpoint as a senior scientist in Federal service, what limitations, if any, affect the role of the Foundation as a balance wheel for Federal support to different fields of basic research?

12. The limitations, in my view, are lack of funds, lack of communications, and lack of flexibility in fund management.

More funding is essential because to achieve proper balance there must be enough money to support adequately a very large number of important areas of science and engineering, and enough to permit shifting of funds from one area to another as the needs change without causing major disruptions in the ongoing, long-range programs.

Lack of adequate communication makes it impossible to determine where funds are most badly needed. As I tried to point out in my statement, closer formal ties between NSF and "mission" agencies (for example, in the form of working committees charged with evaluating gaps in science coverage in areas of mutual interest) would permit more adequate evaluation as to how the "balance wheel" should operate.

Lack of flexibility in the management and distribution of funds prevents NSF from meeting its total responsibility. As long as funding of research within a given area of science or engineering is dependent primarily upon the number and dollar amounts of proposals received and upon the judgment of "peers", a balance will not be achieved. The present system is very effective and should continue but it should not keep the NSF from making its own assessments as to total needs in science (including new areas, "unpopular" areas, etc.) and then encouraging activity irrespective of proposal demand or peer judgment.

13. In the light of your experience with computers at Penn State University, what is your opinion of the current NSF program of replacing several hundred computers which they had acquired for the universities in the late 1950's? Do you believe rental of the computers would be more economical?

13. NSF's program which provides funds for replacement of earlier model computers is an essential one. Computer science is a rapidly developing area of technology both with respect to hardware and application. As in any such area instrumentation becomes rapidly outmoded. Because the progress of American science and technology is inexorably linked to progress in computer development and usage, we must move ahead as fast as this particular branch of our science will permit. Universities, being in the forefront of science, must be equipped with the most modern computers available. Those universities which have been in the computer business for the longest time are the very ones which can use the latest machines to the best advantage. Thus continuous updating is a necessity which can be met only if much more Federal help is available. NSF's program in this area should be greatly expanded.

It is difficult to generalize as to computer rental versus purchase. At my university, Pennsylvania State, we have found it convenient and economical to rent a large part of our computer system but to purchase some of the components that will not become outmoded as rapidly as others. In general, however, because of the rapid developments mentioned above, I believe rental may be more economical in universities large enough to have a computer science faculty and strong graduate research programs. As major changes in computer hardware become less frequent, purchase will probably become more economical than rental.

14. As an employer of varied scientific and technological skills, has Interior observed any problems of early obsolescence of these personnel because of rapid advances in science and technology? If so, what are your views about the role of NSF in devising and sponsoring professional retraining?

14. Obsolescence of skills is a problem in almost all types of work, but scientific and technologic skills can be maintained, and even enhanced, by involvement in or close association with an active and varied research program. Bureaus like the Geological Survey, which include university people as active researchers in the operating program, have less difficult with the obsolescence of personal skills than Bureaus with missions that do not relate them as closely to university personnel and programs.

Professional retraining is essential in many of the Department's activities and the Science Foundation with its experience in science education, should be able to provide guidance and leadership in devising the basic patterns that might then be adapted by the individual agencies to their specific needs.

The Foundation could also do much to alleviate the individual Government agency problems of limited time and funds by supporting the establishment of professional refresher training courses at selected educational institutions through the use of NSF grants.

15. What future emphasis do you think the Foundation should give to engineering research and education in comparison with basic scientific research and education?

15. Since support of both science and engineering is the responsibility of NSF, the two areas should be of equal concern to the Foundation in planning designed to meet national needs. The emphasis to be placed on one area versus the other will change from time to time depending upon the needs and the amount of money made available by other funding agencies in the public and private sectors. To determine how its funds should be divided at any given time, the Foundation must make realistic management-type decisions as to current needs and how its money can best be spent to supplement other funds going into science and engineering endeavors. It should retain its position as the chief Federal source of funds for basic research and leave short-term applied research to other agencies. However, it should assume much more responsibility than has been possible in the past for evaluating and possibly funding the large amount of engineering research that falls between these two extremes and has, therefore, been left out in the cold. The NSF, however, will not be able to take this approach if its funds are not increased very appreciably. At the same time, the mission agencies (particularly those operating in the area of natural resources) will not be able to do their part in closing the gap without similar augmentation of funds.

16. Has the Department had occasion to indicate to the Foundation the desirability of creating new centers of academic excellence in sciences important to your interests? Would such a request be consistent with your understanding of the purposes of the Foundation?

16. The Department has not taken initiative in proposing to the Foundation that new centers of excellence be established. This should be explored and in my opinion this would be consistent with the purposes of NSF. There would have to be a common ground of responsibility; for example, support of a basic science effort in a resources field of interest to Interior.

Again, through cooperative planning on programs in which NSF, Interior, and other agencies have an interest, there has been an Interior contribution to NSF creation of centers of excellence. Examples are the National Center for Atmospheric Research and numerous university oceanographic research centers.

17. The point has been brought during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency X, agency Y, or both. Specifically, what guidelines or criteria has your Department established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of Interior's jurisdiction and, therefore, should, or should not, be supported by the agency? If written criteria have been established, please submit a copy thereof to the committee.

17. The principal criterion for determining whether or not a project is supported by Interior is the subject or purpose of the proposal. Interior's research is mission oriented and even basic research sponsored or conducted by Interior will contribute knowledge to a field of science in our subject areas. Usually there is little difficulty in reaching a decision on whether or not the research is related to Interior's mission.

By contrast the NSF sometimes refers research proposals to Interior for consideration of support because they are of an applied nature in a field of Interior's responsibility.

Criteria for support and guides for submission of proposals have been established by agencies in the Department which support extensive extramural research. These are the Office of Saline Water, Office of Coal Research, Office of Water Resources Research, Federal Aid to Fish and Wildlife and Federal Aid to Commercial Fisheries. Copies of regulations and guidelines materials from these programs can be found in the committee files.

Response by Dr. Arnold B. Grobman, Executive Director, Biological Sciences Curriculum Study, University of Colorado, to Questions of the Subcommittee on Science, Research, and Development

1. In 1959 a report of the President's Science Advisory Committee entitled "Education for the Age of Science" recommended concerning course content that "A mechanism must be found to provide continuous review and revision." Based on your experience with the biological sciences curriculum study, do you think a one-shot effort is sufficient, or should a capability be maintained to periodically upgrade curriculum materials in science courses?

1. I think it essential that a mechanism be found to provide for continuous review and revision of course content. The obvious reasons are that our knowledge of content, and methods of presenting content, are changing daily and the best we know should be brought to bear on education in our schools. There is also a negative effect that could result from a "one shot" approach. If a course were revised by a group of acknowledged experts, and not subject to recision, the resulting new course might itself become a prestige but static course through which the deadly hand of tradition would adversely affect the lively growth of education. I believe that a capability should be maintained to continuously upgrade curriculum materials, especially in science courses, for a new orthodoxy could be just as undesirable as an old orthodoxy.

The frequency of revision would depend on the nature of the particular course and each project should be judged independently on its own merits and goals. For example, a manual on the use of an electron microscope could remain essentially unchanged until such time as the electron microscope itself underwent comprehensive modification. A project of this type would not require the establishment of a permanent curriculum development facility. In contrast, however, a total program of a broad nature in the improvement of education, such as that of the biological sciences curriculum study, should operate continuously in order to keep its materials up to date in content and up to date in reflecting the pedagogical aspects of the program as more knowledge is gained on how students best learn the specific subject.

2. One argument against a continuing revision project is that the development of a permanent group of textbook writers might lead to sterility of thought and isolation from their fields, or to undue influence by one group of men on a particular curriculum. How much of a danger do you consider this?

2. I think there is a potential danger in having a permanent group of textbook writers continuously responsible for the content of one particular course. In the case of the BSCS, I think we were able to effectively avoid this danger by having virtually complete rotation

of the personnel of our major policy committee. With one-third of the committee rotating each year, there has been effected an almost complete rotation every 3 years. Large numbers of people have contributed to the program for varying lengths of time and there are no permanent appointments to the BSCS. The "one group of men" involved in the BSCS consists, to a very large extent, of a significant proportion of the American biologists interested in, and able to devote time to, curricular design. Over 2,000 persons have been intimately involved in the work. In other words, the answer to this question depends primarily on the organization of the curriculum study group. If there are provisions for the substantial rotation of personnel and for the participation of significant numbers of specialists, I see no particular danger in having one group responsible for a course development program and there are a great many advantages. If there are not provisions, however, for substantial rotation of personnel and utilization of many persons, I feel the group should simply complete a "one shot" job and then a new group should be organized as revision time approaches.

If the criteria listed above are not met, there could be a danger that control of curriculums could fall into the hands of a small group of individuals who could strongly influence education throughout the United States. This would, of course, be deplorable. In terms of the BSCS, however, just the reverse has occurred. For the past 30 years, the textbooks used most widely in the teaching of biology were written by the same small group of individuals who did not have access to substantial counsel from professional biologists and high school biology teachers. Authors of those texts prepared manuscripts following the recommendations of publishing houses based upon sales records. A continuously operating curriculum study, with a rotation of personnel involving professionals from all areas of education concerned with the teaching of science, is a safeguard against the danger that any one group of individuals would introduce sterility of thought or produce orthodoxy as has been the case in biology prior to 1960. I do not think there is any danger that properly organized and operated curriculum studies would produce this kind of control but, to the contrary, such curriculum studies would tend to prevent the sterility of thought that we have been faced with for the past generation.

3. Referring to your memorandum of June 11, 1965, addressed to the BSCS executive committee, are you aware of any critical analyses of like nature on the National Science Foundation's funding operations and the fiscal management of its programs?

3. I know of no document analogous to the memorandum of June 11 to which reference is made. Informal conversations with other NSF grantees, however, has led me to believe that the criticisms in the memorandum are representative and would be affirmed by the directors of many NSF-supported projects.

4. You testified on July 29 that alternative sources of financial support for BSCS, or other curriculum study groups, might be private foundations or the U.S. Office of Education.

(a) Considering the growing authority and funding of the Office of Education and its close contact with the educational system, should the Foundation's interests in curriculum revision for scientific subjects be shifted to that Office?

(b) Do you think that fiscal control by the Office of Education would be free of the management difficulties ascribed to NSF in part V of your statement—particularly "undue policy control"?

(c) How much policy control would be exercised by private foundations?

4. (*a*) My general feeling is that the support of curriculum development and revision has been so successful in the sciences that it should be extended across the board to all areas. It becomes proper, therefore, to ask whether this function should be removed from the Foundation and given to a broader gaged agency like the Office of Education. My general reaction is that this should be done, but it should be done cautiously because the Office of Education has not yet established, in my view, an authority and prestige comparable to that of the Foundation in the area of curriculum revision and design. With the new leadership and increased funding of the Office, it is likely that this might come to pass. Perhaps the way to proceed with caution would be for the support of projects to be moved from one agency to the other in a stepwise fashion. For example, the Foundation might continue to fully support the design and revision of course content projects except, initially, that the related aspects dealing with the preparation of teachers be funded through the Office of Education. With successful experience in this division of funding, perhaps the matter of studies of instructional media and pedagogical procedures could then be transferred to the Office from the Foundation. A last step would be the matter of the transfer of the funding of the design of the course content itself. Such a three-step sliding procedure in transferring the responsibility for funding might provide both agencies an opportunity to adjust to new requirements and might provide a period of testing during which an evaluation could be made of whether the Office of Education could assume the responsibility in an adequate way.

(*b*) I have no direct experience to indicate that fiscal control by the Office of Education would be more or less restrictive than that of the NSF but I have been advised by colleagues that it is now more restrictive. If my information is correct and this situation continues to prevail, a transfer of support from the NSF to the Office of Education would be undesirable because many good scholars and scientists simply are not willing to work on projects burdened with restrictions they feel are unwarranted.

(*c*) Our experience with the Rockefeller Foundation has been close to ideal. General terms of a grant were agreed upon in the first instance and no important contacts between the BSCS and the Foundation were necessary until the submission of a final report. Our Rockefeller grants have been the most permissive we have received and, for this reason, the most valuable to us. Our experience with Asia Foundation grants was similar. The general reply, then, to the question is that BSCS's experience with grants from private foundations has involved virtually no policy control by the foundations. I understand from other colleagues, however, that this is not always the case with grants from the Ford Foundation.

5. Are the principles and methods of curriculum improvement outlined in your statement applicable also to the social sciences? If so,

should social sciences curriculum studies be supported by NSF? By the O. of E.?

5. The general principles of curriculum improvement are fairly simple. What is required is the bringing together in meaningful cooperation the scholars in a field and the teachers of that field in an environment conducive to collaborative effort. The second step is widespread and honest evaluation of the materials in live classroom situations, repeated as appears necessary, with the final production of classroom materials dependent on such rigorous testing. Supplementary materials, of course, need to be developed along the way. This general procedure should be equally applicable to the social sciences as to the sciences. It is extremely desirable that substantial support be given to the social sciences and humanities for curriculum improvement. I doubt if the NSF would be the appropriate home for the funding of social science curriculum improvement because the personnel of the Foundation is now drawn almost exclusively from the sciences. With its growing authority and prestige, the Office of Education might become an appropriate place for such funding to be housed.

6. In your view, which is the more important mission of NSF—the promotion of scientific research or the advancement of science education?

6. Both missions are important and are interrelated. Likewise the missions of improvement of science education and the improvement of social science education are equally important and are related to each other. If the advancement of education, through curriculum improvement among other ways, could be satisfactorily housed in the Office of Education, then I think the mission of the NSF might be profitably devoted to promotion of research in the basic sciences, recognizing that certain applied aspects are already being substantially funded by the National Institutes of Health, the Atomic Energy Commission, the National Aeronautics and Space Administration, and other Federal agencies.

7. Granted that the upgrading of education in the sciences is desirable and that the curriculum revision has been successful, to what extent would it be desirable to extend curriculum revision to the course material for training technicians needed to work with scientists and engineers? For what reasons might the Foundation support curriculum research and revision for the growing number of 2-year community colleges?

7. I am not sure whether or not there is a serious problem regarding the revision of course materials for potential technicians. Perhaps a simple way to determine the advisability of such projects would be to discuss the matter with a representative group of persons who are responsible for the training and utilization of such technicians. On the other hand, I am convinced that a good deal of work needs to be done regarding curriculum research and revision for the burgeoning number of 2-year colleges and I believe that much could be done to assist these institutions in improving the caliber of their offerings.

8. We have heard it said that the college entry examinations boards have not been revised to take into account the new curriculums being devised in mathematics and the sciences, and that students who take the old-style courses may score appreciably higher on the examinations.

What has the BSCS or the Foundation done to secure recognition of these new curriculums by the entrance tests?

8. The college entrance examination board is apparently an extremely conservative body. It has a number of policies which tend to work against change in curriculums. For example, it believes (properly so) that its examinations should reflect what is taught in the schools rather than what the CEEB (or anyone else) feels should be taught. Hence it tends to "follow" curriculums rather than "lead" curriculums. This general position inhibits teachers and others from trying out new ideas because such new ideas would not be tested by the CEEB exams until they became used rather generally. In essence the CEEB exams tend to put a floor under achievement but they also tend to place a ceiling on experimentation. As far as the BSCS and the CEEB are concerned, both organizations have been in frequent (and discouraging to us) contact with each other. In the earlier days of the BSCS program, extensive tests were given to students taking BSCS courses and students taking traditional biology courses. The results, in general, were about as follows: students taking BSCS courses and students taking traditional courses did equally well on CEEB (traditional) examinations; and students taking BSCS courses did substantially better on BSCS examinations than students taking traditional biology courses. (This latter result could have been anticipated because the traditional and the BSCS courses are rather different.) Based on these results, the BSCS has insisted that CEEB has the obligation to prepare two College Entrance Board examinations in biology: one for students taking traditional courses and one for students taking BSCS courses. The CEEB response has been that a single examination is sufficient because BSCS students and non-BSCS students do equally well on the CEEB exam. The implication is that the CEEB exam measures both groups fairly. The CEEB has been unwilling to recognize that the CEEB exams do not take into account some of the important materials BSCS students are learning, over and beyond what non-BSCS students are learning.

There is very little else, to my knowledge, that can be done to convince the CEEB of the magnitude of the problem. On the other hand, the problem is going to take care of itself because, as things are now developing, the "standard" type of biology (upon which CEEB exams are based) will become more like BSCS and less like traditional biology in a very few years. It will, therefore, probably follow that the CEEB exams will be gradually altered to reflect this trend.

I do not believe the Foundation should become involved directly in this problem since the CEEB is a purely private organization. I do believe, however, that the Foundation should not fund any projects initiated by the CEEB or its parent, the Educational Testing Service, until those organizations exhibit greater responsiveness to change in their testing programs. On its part, the BSCS is seriously considering designing and marketing its own biology exam which would presumably compete with and probably replace the CEEB exam. It is most unfortunate that CEEB failed long ago to take adequate cognizance of the very great changes taking place in education through the major curriculum studies.

9. Subsequent to your testimony, the suggestion was offered that a "comparative study" be made of the various curriculum study groups

in the country, for the purpose of evaluating their course content improvement criteria, assessing publications problems and procedures, and examining instructional materials that are developed. What would be required in terms of staff personnel, time, and travel to complete such a study?

9. I understand that the Carnegie Corp. has been invited by the U.S. Commissioner of Education to conduct a study of the feasibility of making a national assessment of educational achievement. Such a study, I would assume, might cover part of the inquiry indicated in this question.

To conduct the study proposed in your question would require an alert and imaginative director, of real competence, who would report to a rather representative policy board. For each of the several disciplines, consultants would be needed to review the criteria upon which each of the curriculum study groups based its work on content improvement. Perhaps a single panel could assess publications problems and procedures since these would probably fall into a few major categories. If more than a cursory examination of the instructional material produced is envisaged, a tremendous effort would be required. However, if just a brief review is made without an attempt at depth evaluation of the developed materials, then a large staff would not be necessary. Confining the study in this way, a modest investigation should be appropriate. Such a study could be confined to the major curriculum study groups and each group should be visited by a team of about three consultants. Only a sampling of the smaller study groups would seem to be indicated and they might supply some information through questionnaires. The major study groups would seem to include: one in physics, two in chemistry, one in biology, two in mathematics, two in earth sciences, one in junior high school science, and two in elementary school science. Assuming a visit to each study of 3 days by 3 persons, plus three 3-day meetings of a policy committee of about 12 persons, and the 6-months' salary of a director (who would do this job on a leave of absence basis) and his clerical staff, the net cost might be something in the neighborhood of $60,000.

10. A supporting recommendation of the 1959 report of the President's Science Advisory Committee entitled "Education for the Age of Science" was the preparation of challenging, stimulating, and exciting textbooks and auxiliary reading materials in mathematical and scientific fields, priced so that a larger number of students will be able to build their own libraries. What does your experience with BSCS suggest about the feasibility and desirability of the Foundation sponsoring such projects?

10. Our BSCS experience does not give us specific clues to this query, but I am completely sympathetic with the suggestion that the Foundation support such projects. Teachers indicate real interest in such materials.

11. The hearings indicated that users of scientific information are not clear as to what Federal resources are available to them. Please report what use, if any, you have ever made of:

(a) The Clearinghouse for Federal Scientific and Technical Information, National Bureau of Standards.

(b) The Science Information Exchange, Smithsonian Institution.

(c) The National Referral Center for Science and Technology, Library of Congress.

(d) The Office of Scientific Information Services, National Science Foundation.

Please evaluate the usefulness of these sources and describe any problems you may have encountered.

11. In my work in administering the BSCS I have not made direct use of any of the sources listed, although I have scanned the NSF Scientific Information Services reports, which have contributed to my background knowledge. To what extent the actual writers of the BSCS materials used the items listed I do not know but I would guess that it has been rather minimal.

12. You had a parenthetic reference in your statement to "the extensive overseas activities" of BSCS. Could you briefly describe your foreign program? Should NSF assume a more active role in the support of international science projects?

12. The BSCS overseas program is very extensive and continues to grow at a very rapid rate. It is important to note that all overseas programs involving the BSCS were initiated by individuals in the various countries and not through solicitation by the BSCS itself. Biologists in many overseas countries had obtained copies of our materials and independently made the judgment that these materials could be useful in their countries. The BSCS, on its part, has taken the position that its materials should not be directly used overseas. Rather, they should be adapted to fit the flora, fauna, educational system, and social mores of the overseas country involved. To accomplish this, adaptation committees of local biologists and educators were indicated. Hence, when we received requests for direct use or permission to translate our materials, we recommended that a local adaptation committee be organized and suggested that we would be glad to cooperate with such a committee. Overseas adaptations of BSCS materials are thus produced largely by their own writers and published by their own publishing houses. In brief, this is not an export of Americana to other countries. In each case the adaptation of BSCS materials belongs to the respective country whose biologists found BSCS materials to their liking. Our recent "International News Notes" gives you some idea of the scope of our program. (A copy in committee files.) In brief summary, the following is the situation:

A group in Colombia is now preparing a second edition of a biology course designed for tropical America, in Spanish, based upon our Green Version. It is being, or has been, tested in all, or in part, in El Salvador, Guatemala, Colombia, Ecuador, and Venezuela. It has been studied by biologists in other parts of Central America and northern South America as well. The BSCS has assisted in the training of 50 Peace Corps volunteers who will be assigned to biology teaching in Colombia. In Brazil, a group of biologists has made specific adaptations and translations into Portuguese of both our Blue and Green Versions; these are now in press. In Argentina, a local adaptation team has prepared a biology course for use in temperate South America, in Spanish, based on our Green Version. This is being tested in Argentina, Peru, Chile, and Uruguay. A Portuguese-speaking American biologist, familiar with the BSCS program, spent 6 months in Brazil with the local writing team and we have been able to arrange

for BSCS writers to visit Colombia and Argentina for shorter periods. Members of the writing teams from the Latin American countries spent the summer of 1961 in Boulder working with BSCS writers and we have had a resident consultant in Central America. There has been considerable interchange of information and at least two Inter-American Conferences on the Teaching of Biology have resulted from these activities.

An adaptation team has been established in Quebec to prepare an adaption and translation of the Blue Version for use in French-speaking Canadian schools.

In Japan, an adaptation and translation of the Blue Version is underway with two BSCS writers in residence in Tokyo for part of the summer to work with the Japanese adaptation team.

In the Republic of China (Taiwan), an adaptation of the Yellow Version is being accomplished through a committee of Chinese biologists. The chairman of that committee is spending 9 months in Boulder working there on the adaptation. Also in Boulder is the chief artist of the Taiwan adaptation team.

In the Philippines, there has just been published a Philippine adaptation of the Green Version which had previously gone through an experimental edition. A well-organized adaptation team consisting of six Filipinos and one American (a BSCS writer) effected a very successful program which resulted in the first biology book ever prepared for Filipino conditions. The work has been so highly regarded that the Ford Foundation has recently financed a whole series of curriculum projects in Manila covering grades one through high school.

In Thailand, an adaptation of the Yellow Version laboratory manual has been completed and is being tried out in a number of schools. Two Thai writers spent the summer of 1961 in Boulder working with the BSCS.

An authorized adaptation and translation of the Yellow Version has been made in Russia, and several abridged and unauthorized adaptations of BSCS versions have been made in Taiwan.

In India, the BSCS (with AID support) conducted a summer institute for high school biology teachers in 1963 based upon the Yellow Version. Because of the success of the initial institute, four such institutes were conducted in 1964 and seven more institutes in 1965. Permission was given the Indians to prepare a reprint of the Yellow Version in anticipation of the establishment of a writing team to prepare a specific adaptation for use in India.

Considerable interest in the BSCS materials exists in England, and a group there publishes a BSCS British newsletter describing their activities in England. There are plans to prepare an adaptation of the Green Version. In the meantime, all three versions are sold freely in England.

In Australia, a very active adaptation team has been established with the goal of completing an adaptation of the Green Version within a 2-year period. The secretary of the team will be in the United States shortly to visit BSCS headquarters.

An active adaptation team is working in New Zealand and one of its members was recently in the United States to visit and compare procedures.

Demonstration classes of BSCS materials have been taught by experienced persons (either natives or Americans) in the Netherlands, Denmark, Italy, Mexico, Turkey, and Norway.

Conference on BSCS materials have been held in many countries, including Nigeria, Ceylon, Kenya, Singapore, Hong Kong, France, Switzerland, and elsewhere.

Serious overseas visitors to BSCS headquarters average about 1 a week. Most visits are for several days' duration, and the visitors are genuinely interested in studying the process of curriculum revision and seeing the results of our work.

BSCS writers or staff members have visited all of the countries indicated above as well as Peru, Nicaragua, Costa Rica, and Honduras and have worked within the framework of OECD and UNESCO.

Many overseas publishing companies are anxious to have rights to translate and publish our versions, pamphlets, laboratory blocks, and other materials. Most of these offers are being declined because of our feeling that the material should be specifically adapted before being used in overseas nations. The results of this position seem to be that the participating countries are improving their education in biology; they are doing it largely by their own efforts with cooperation and assistance by Americans; there is resulting a large number of person-to-person contacts between biologists in the States and overseas; and leaders in the overseas countries are looking to the United States for contacts in their work in improving biological education.

It seems to me that this is possibly one of the least expensive and most successful international programs in which the United States is engaged. Most of our work has been done on a shoestring budget with small sums of money being made available by the Rockefeller Foundation, Asia Foundation, and, indirectly, AID through the NSF. More substantial support for this activity should certainly be provided. I think there is no question that great benefits would accrue to both the United States and to the participating nations through increased NSF support of international science projects such as that described above.

13. What contacts has the BSCS had with biostudy groups of the National Academy of Sciences?

13. A study group was set up by the National Academy of Sciences National Research Council to prepare a source book for high school teachers of biology. This "Source Book of Laboratory and Field Studies in Biology," produced at Michigan State University in 1957 under the aegis of the NAS–NRC, could be considered the precursor of the BSCS. As the BSCS developed later, it borrowed heavily from the "Source" book and took considerable advantage of the work of the National Research Council. As another example, in selecting persons to be invited to the BSCS writing teams, the files in Washington of the NRC were carefully reviewed by the BSCS. Reports by earlier NAS–NRC study groups, especially those of the late 1940's, were read carefully by BSCS writers. I do not recall any substantial contacts between the NAS–NRC and the BSCS during the last 3 or 4 years.

14. What evidence have you seen that the textbook publishers are more likely to do a better job upgrading and revising curriculum materials developed through NSF funding than they did before NSF

undertook support of such programs? Can the Federal Government withdraw and still expect the quality of texts to be maintained at the desired level?

14. I have no evidence that yet indicates the textbooks publishers are likely by themselves to upgrade and revise their books without outside support. If left solely to their own devices, I am afraid that publishers would respond to the nonacademic marketplace control and gradually reduce the contents of their books to low standards. I am convinced that the withdrawal of support by the Federal Government would adversely affect the maintenance of the quality of our books at a desired level. The structure of the textbook industry is simply not conducive to the production of rigorous and modern curriculum materials for the public schools. On the other hand, Federal support of study groups in no way precludes an individual publisher from proceeding in an independent and competitive way if he wishes.

15. Will improved curriculums make it possible to teach a sharply increasing student population without a corresponding increase in numbers of faculty? Will it change training of teachers or alter student-teacher relationships? Can these curriculums or similar ones be employed where the objective is retraining?

15. I do not think that improved curriculums (of the kind I have been discussing) would make it possible to significantly alter the faculty-student ratio. In fact, the ratio is too high now and we need more teachers per given number of students rather than less. The new curriculums place a heavy demand on teachers as well as students.

The new curriculums should encourage significant modification of the training of teachers and I hope that teacher preparation institutions will begin to recognize this need more generally than they have. The relationship between students and teachers should change with these new science curriculums. The relationship should become one in which the teacher is more of an interested leader in a search for knowledge and information rather than an authoritative warehouse of knowledge and information. I think that the new curriculums are ideal instruments for the retraining of teachers whose original training was along traditional lines. Retraining is, in many ways, a more difficult task than training students de novo.

Response by Dr. Jerome B. Wiesner, Dean of Science, Massachusetts Institute of Technology, to Questions of the Subcommittee on Science, Research, and Development

1. We have heard the allegation that the National Science Foundation is, in a sense, becoming the creature of the university community—that is to say that virtually all of its funds are dispensed to universities. Furthermore, about two-thirds of the members of the National Science Board are associated with universities, as are most members of the advisory panels. Do you see any danger in this? Might it not be a good idea to have more representation from the nonprofit organizations, the foundations, and the business community—many of which are deeply involved with basic research?

1. When the National Science Foundation was established, the Board was created to provide a buffer between the Federal Government and the scientific community in order to insure the continued independence of the universities where it was expected that most of the research supported by the NSF would be done. Care was taken to see that the Board membership was widely representative of the research community and that its members came from all regions of the country. Because the bulk of the basic research supported by the NSF is done in universities, a majority of the Board members were drawn from the academic sphere, though its membership has always included some outstanding industrial scientists.

To the extent that the Board's primary function is to insure the well-being of the basic research effort in universities, it appears wise to continue to recruit a majority of the membership from among people closely associated with academic institutions.

Obviously, it is necessary to consider the general welfare in making policy for the NSF. Balance in the NSF program is provided by a variety of means. The nonacademic members of the Board help to some extent in this respect. The Director and staff of the Foundation, as Government employees, also have a responsibility to be concerned about broad national problems. The President, advised by the PSAC, his Science Advisory Committee, the Bureau of the Budget and his Cabinet, also has a major responsibility for establishing goals for the NSF. Finally, the Congress has always had an important role in shaping the character of the NSF program. (Unfortunately, Congress has too often restricted the scope of the NSF.) Considering the sweep of nonacademic influences on NSF policy, it probably remains desirable to draw the Board membership predominantly from the university research community.

2. In your testimony on August 3 you expressed opposition to a deliberate policy of uniform geographic distribution of NSF grants.

At the same time you advocated building up new centers of academic excellence. How do you reconcile these two views?

2. I believe that special funds should be provided to build up centers of academic excellence. Such special support should be for a finite time after which the institution thus assisted should have to compete on a basis of research competence for continuing support. Any basis for allocating research support which ignores or discounts excellence will degrade the quality of American research, damage the good schools and lower the quality of scientific education. I believe that it is possible to build up promising institutions without jeopardizing those already first rank, provided we are prepared to be careful and thoughtful, but a policy of homogenization will seriously damage our great scientific enterprise.

3. You agreed with certain committee members that more attention is needed to research in the social sciences, in order that our society may fully benefit from the advances in the physical sciences. Yet you disagreed with the suggestion that social sciences be mentioned in the NSF Act. How, then, would you propose to give status to the social sciences in the NSF program?

3. I believe that the NSF should be instructed to expand its program in the social sciences and given the resources needed to do so.

4. It has been suggested to the committee that while NSF should not attempt to evaluate the work of other agencies, it can and should evaluate the state of individual scientific disciplines throughout the Government and give weight accordingly in its research grants. Do you agree with this?

4. I believe that it would be useful to have the NSF sponsor evaluations of individual scientific disciplines. The work should probably not be done by NSF staff members for it should be done by the very best people in a discipline and few such persons are likely to be employees of the NSF. Possibly this work could be done by consultant panels working directly for the NSF. Alternatively, it might be done for the NSF by the National Academy of Sciences. Such information should be considered in planning NSF research support.

5. From the standpoint of objectives, program content, and management, which of NSF's programs do you consider to be the best, and which do you consider to be the least effective?

(a) What are NSF's notable weaknesses or deficiencies, and how may they be corrected?

5. I am not familiar enough with all of the NSF programs to be qualified to compare the various programs, but I believe that the behavorial sciences, chemistry, mathematics, educational research, and the engineering programs are inadequate. I also believe that the NSF needs to expand its scientific and management staffs. Possibly it should attract more scientists to temporary assignments with the Foundation as is done in the DOD.

(b) In your judgment what more could the Foundation do to promote the progress of science?

I believe that the NSF budget is not adequate to permit it to fulfill its responsibilities adequately. It received approximately $420 million in 1965 to support many different activities. Approximately $200 million was spent for supporting basic research, while a great variety of educational activities, including the granting of fellowships, support-

ing developing institutions, upgrading teachers and teaching facilities in high schools and colleges received approximately $120 million. About $11 million was spent on improving the dissemination of scientific information. Substantial sums were also spent on facilitating international cooperation and supporting several national scientific centers. In contrast, NASA gets more than 10 times as much money for space activities alone.

6. You indicated in your testimony that the Foundation should exercise a balance wheel function at a time when Federal funding for science and technology is changing. Can you expand on how this might be done?

6. Several of the mission-oriented agencies have found it necessary, or desirable, to restrict the growth of their basic research support so that fields which they have traditionally supported are pinched. As examples, the Navy has not been able to meet growing needs of oceanographic research, and the AEC has leveled its support for chemistry. Whenever this happens, the NSF should be directed to assume the responsibility for providing that margin of funding needed to insure that support for the particular branch of science is adequate. As part of the budget process, the OST and the BOB prepare a summary of Government support planned for the various scientific disciplines. These figures could be compared with the NSF estimate of the overall need in each area, and then the NSF could be charged with the responsibility of insuring that adequate funds were availbale for each.

7. How much basic research of interest to mission-oriented departments and agencies should be financed by the Foundation? What would be the appropriate departmental and interagency responsibilities for planning and funding and selection of fields of science and individual projects?

7. I don't think one can generalize about this. If the field of basic research is of general interest and importance, the Science Foundation should support it vigorously. If, on the other hand, the work is of little general interest and does not appear to contribute significantly to our understanding of the universe or living things in it, it is probably all right for support of the area to be the sole responsibility of a mission-oriented agency. It is extremely desirable to have more than one agency in a position to support basic research in any field. Consequently, the NSF should, in principle, stand ready to support an outstanding proposal in any field if the cognizant mission-oriented agency does not want to do so for some reason.

While it is obviously hard to defend any specific ratio, the Science Foundation portion of an important field should be sufficiently large that its policies can play a role in shaping the development of the discipline. I believe that providing half of the support for a given area would probably accomplish this.

The planning of the funding should be done by a cooperative effort involving the OST, Bureau of the Budget and NSF.

8. Considering the change in budget trends for research and development reflected in the fiscal year 1966 budget, does the President's Science Advisory Committee's manpower goal of 7,500 Ph. D.'s and 30,000 masters' degrees annually by 1970 need revision?

8. I don't believe that the PSAC goal of 7,500 Ph. D.'s and 30,000 masters' degrees by 1970 needs revision. These numbers were deter-

mined from the estimated maximum educational capability, not from a projection of need. In 1963, when the PSAC goals were set, the need appeared to be substantially larger than the targets that were established. Quite apart from the requirement for more scientists and engineers, there is a need to provide better educated people for many jobs currently filled by someone. Too many teaching positions in colleges and engineering schools are inadequately prepared, and too many important development projects are staffed and managed by inadequately trained personnel. Furthermore, I believe that it would be desirable for scientific or engineering educations to be used as the basic education for a substantial number of persons who ultimately will work in nontechnical professions.

9. What examples can you draw from your experience to show contributions by the Foundation to the shaping of national science policy within the executive branch?

9. The NSF made a major contribution to the studies which led to the PSAC scientific and technical manpower objectives discussed above. The NSF has financed many national academy studies of the scientific potential of specific disciplines, and these have been essential in the planning of science policy within the Government. In fact, NSF statistical studies have provided the basis for much of the planning that has occurred to date. Also, NSF studies of Soviet and Chinese science have played an important role in our understanding of the research efforts in these countries.

10. Do you believe that, in attempting to spread its research supporting budget over as wide an area as possible, the Foundation is spreading its resources too thin? In other words, would it be more effective to have fewer research grants funded more heavily and for longer periods of time?

10. I believe that NSF resources are spread too thin and that this does result in short-term and inadequate funding of many research projects. But given the volume of good work that needs support, I think that the NSF has done the right thing in allocating funds as they have. The money available to the Foundation for the support of basic research is grossly inadequate to support properly the wide range of activities which they must cover.

If the sole purpose of the NSF research grants was to insure performance of a maximum amount of high-quality research in the near term, it might prove appropriate to distribute the funds differently, giving more to the outstanding groups and not supporting the barely adequate groups. This would obviously be contrary to the present trend in which long-term needs, education, institution building, and geographic well-being are increasingly considered to be important.

11. How can the relatively low science education budget of the Foundation act as a balance wheel against the large sums spent in institutions of higher learning by mission-oriented agencies? Should not the NSF have a say in how all Federal basic research funds are allocated?

11. The best way for the NSF to play a more important role in determining the character of Federal support in universities is for it to support a larger fraction of the research and teaching activities that are Government financed. I believe that NSF should have responsibility for between 25 and 50 percent of the Federal support of such

activities. This goal can only be accomplished by allowing the NSF budget to grow more rapidly than that of the other agencies.

I don't believe that the NSF should have detailed control of all basic research funds, because I believe that the advantages which flow from diversity of support should be preserved, but by a combination of the integrated planning of the level of support for individual disciplines and operational coordination between agencies, coherence should be provided. Effective operation and use of the science information exchange could help greatly in this aspect of the problem.

12. How should the role of the Scientific Information Services of NSF be fitted into the total Federal scheme for collecting and disseminating scientific information?

(a) Do you believe the coordination of all scientific and technical information gathering should be the responsibility of the Office of Science and Technology? If not, what share should accrue to NSF?

12. I believe that it should be the OST's responsibility to insure that the Nation has an adequate science information system and consequently OST should assume primary responsibility for policymaking. Actual operations should be delegated to the operating agencies for work in fields where they have unique competence such as NASA for space, the AEC for atomic energy or HEW for health research. In areas where no single major competence exists, it would be appropriate to assign responsibility to the NSF.

(b) How should NSF make use of the Science Information Exchange?

The purpose of the Science Information Exchange (SIE) is to make available information on individual research projects. When I last had contact with it, its files covered the life sciences adequately, but not the physical sciences, so that it was of limited usefulness in science planning. Assuming that it can be brought up to an adequate level of coverage, it can be used by the NSF in judging the adequacy of research efforts in various disciplines, in making judgments about relative levels of support between areas and between institutions. Information stored in the SIE can also be useful in making decisions about individual grants. The information is also useful for working scientists and research supervisors.

(c) In forming the Committee of Scientific Information (COSI), the predecessor of the Committee on Scientific and Technical Information (COSATI), in May 1962, did the Federal Council for Science and Technology actually remove the coordinating responsibilities from the Foundation?

As I recall, the Committee on Scientific and Technical Information was established under the jurisdiction of the Federal Council for Science and Technology in accordance with the Executive order creating the Council. It was not necessary to remove any science information coordinating responsibilities from the NSF because they had not been assumed. Reorganization Act No. 2 of 1962 clarified the division of responsibility between NSF and OST.

13. Since it appears that the biological sciences are ready for a great expansion, what should be the respective responsibilities of the Foundation, the National Institutes of Health, the Department of Agriculture, and departments with marine biology interests for spon-

soring basic biological research and education of students in the biological sciences?

13. I don't have sufficient knowledge of the individual programs to comment on the proper division among the agencies supporting basic research in the biological sciences. NIH should continue to have a major role, but NSF should also be encouraged to have an active, growing program in this area. The Department of Agriculture has not had an enlightened approach to the support of basic research and should be compelled to develop adequate objectives and standards before it is permitted to have a substantial role in the support of basic research in academic institutions.

14. While the Foundation began as an agency to sponsor basic research, it now operates four national laboratories, directs the Mohole project, and provides major services relating to scientific and technical manpower and to technical information. What would be the advantages and disadvantages of divesting the Foundation of all operating and service functions so that it could concentrate upon basic research?

14. I believe that there is a misunderstanding here. The NSF does not operate four national laboratories; it provides funds to support research centers that are managed by nonprofit associations of universities whose faculties are interested in using the facilities. In these cases the facilities in question—for example, the National Center for Atmospheric Research—are too large and expensive to be available to individual universities and cooperative enterprises are necessary if adequate facilities are to be provided for anyone. I believe that it is proper and desirable for the NSF to support such institutions provided that it can be demonstrated that the scientific need justifies the special arrangement and, in addition, provided that a responsible management scheme can be devised.

Totally inadequate attention was paid to the preceding matters when the Mohole project was initiated. I believe that the NSF should not become directly involved in the management of research projects, as it did in this case.

If the NSF were divested of responsibility for national centers for doing basic research, this function would have to be assigned to another agency, or possibly distributed among a number of agencies. I don't believe that this would be a desirable step because it would create an artificial division between fields of academic research which required large facilities and those that did not. Such a move would certainly make the planning and coordination functions more difficult. The only motive for such a move that I know of is to make more funds available for individual project grants. Since the cost of supporting the national centers would still fall on the Federal Government, fiscal opportunism hardly seems to be an adequate reason for trading a good administrative arrangement for a poor one.

I don't have strong views on the matter of the service functions performed by the NSF and relating to technical manpower and technical information. Past efforts in both of these fields have been inadequate, and there have been numerous attempts through the years to improve and enlarge upon them.

It is now generally agreed that the NSF should not attempt to coordinate the science information programs of the Federal Government and this responsibility is now, as noted earlier, lodged in the OST. The NSF has and should continue to have an active and effective program to support translation of foreign scientific publications. Finally, I believe that the information retrieval, information processing and communication research and development programs are on too small a scale to solve the problems. Logically, the activity belongs in the Science Foundation, but if funding limitations make it impossible to support an adequate program in the information processing field without an undesirable impact on the basic research effort, the responsibility could be given to another agency.

15. Considering recent attention to the role of smaller colleges in higher education, what responsibility should the Foundation have for possibly changing the present structure of higher education by selectively directing support to smaller colleges for basic research and for education and training of scientists and engineers?

15. I believe that it is necessary to provide assistance to most of the smaller colleges if they are to develop adequate science teaching programs. The assistance must include financial assistance for salaries, for equipment, and for some research. Since most of these colleges do not and, in most cases, should not have graduate programs, the research efforts should be on a much smaller scale than in a school that has a substantial graduate training program.

It would take a major effort to properly solve the small college science program. In my opinion it is necessary to make an organizational invention to attract an adequate number of good faculty to these colleges. Several things are needed—better salaries, an arrangement that provides an association with vigorous research effort, a similar association with curriculum development activities and funds to obtain and maintain adequate laboratory and other teaching equipment.

Possibly a science corps, whose members were supported in part by the NSF and in part by the institution which they serve, could be established. Members of the science corps could spend some years teaching and others working in university research centers, in Government activities or on curriculum development programs. In this way they would be helped to retain a professional orientation. Incidentally, your questions seem to imply that the major reason for improving science teaching in the smaller colleges is to improve the education of future scientists and engineers. I believe that it is equally important to provide equally good, though not necessarily the same science education for the nonscience majors who comprise the bulk of students in the smaller colleges.

RESPONSE BY DR. NYLE C. BRADY, DIRECTOR OF SCIENCE AND EDUCATION, DEPARTMENT OF AGRICULTURE, TO QUESTIONS OF THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

---

1. Earlier this summer, in a statement to the Subcommittee on Employment and Manpower of the Senate Committee on Labor and Public Works, you said that the Department of Agriculture believed it would benefit from, and would seek, broader authority and increased funds to expand its project grants.

(a) Does this imply dissatisfaction in the use of institutional grants which have been the backbone of Agriculture's support system?

(b) What disadvantages of institutional grants have you experienced that the National Science Foundation should keep in mind when planning increased institutional support?

(c) Just how should the Foundation select universities and colleges for institutional support?

(d) What factors should be evaluated besides educational merit? For example, should consideration be given to such things as geographical location; to climate, or population density or political status?

1. (*a*) The Department has sought broader research grant authority. This does not imply dissatisfaction with the statutory grants to State agricultural experiment stations, which has been the backbone of Agriculture's research support system for 75 years. It is rather a recognition of the fact that the Department's mission can best be served by a combination of research grant authorities. This has been attained recently with the enactment of Public Law 89-106.

(*b*) The disadvantages of institutional grants, particularly true when they are largely distributed by formulas as provided under the Hatch Act, is the inability to concentrate support for research on major problems in sufficient depth and intensity to attain rapid progress.

(*c*) Criteria for selecting universities and colleges for institutional support by National Science Foundation should be primarily the research training potential adjudged to exist among the institutions being considered. There should be existing competence of a relatively high degree and plans for developing and sustaining high competence. There should also be provisions for some cost sharing by the institutions.

(*d*) We believe that this Department's experience provides a good case study in the merits of providing a widely dispersed base of research institutions. Geography and population density are relevant factors in determining this base. Political status as reflecting support of local community and local or State governments also is important. This might be summarized as a philosophy which provides

for the establishment and support of research centers which nurture talent rather than simply to seek research talent and support it.

2. The subcommittee has heard arguments that the level of basic research financed by the Foundation should increase 15 percent annually to compensate for increasing enrollment and increasing costs of equipment. In your experience, has a constantly increasing research budget been necessary to achieve your goals?

2. Since the research program of the Department is strongly mission oriented, its rate of growth has been determined by the urgency of problems rather than by the increase in college enrollment and increasing cost of equipment. The annual rate of increase in funds support during the past 10 years has been of the general magnitude of 10 to 12 percent. A substantial part of such increase has been absorbed in rising costs.

3. As one of the members of the Federal Council for Science and Technology, do you feel that the Foundation should exercise a larger, or a coequal role with other agencies, in the development of national science policy? In your opinion, how has the Foundation assisted in the development of national science policy?

3. We believe that the National Science Foundation should exercise a major role in the development of national science policy, and that in general it probably should be coequal with other agencies such as the USDA. The Foundation undoubtedly has assisted materially in the development of national science policy, particularly in assuring a strong program of non-mission-oriented basic research. Its fellowship programs and the strong program of scientific information also are noteworthy.

4. The Department of Agriculture is unique in that some 20 percent of its research staff is located at State experiment stations or facilities operated by State stations. This is one approach to research and education that has not been explored by the Foundation. What does your experience with this off-site research by your staff indicate as to its value as a way to strengthen teaching of science in smaller colleges and universities that are finding it difficult to retain good science faculties?

4. The 20 percent of the Department's research staff located in land-grant college facilities are full-time research workers and have had very limited opportunity to participate in teaching programs. Teaching time with State workers is gained only by exchange of tour arrangement or teaching outside regular tour of duty. The most effective contribution is the supervision of graduate students serving as research assistants.

5. Supplementing your statement submitted to the committee on July 29, what are the long-range projections for future growth of basic scientific research activities within the Department of Agriculture?

(a) To what extent do you foresee the Foundation exercising a "balance wheel" role in regard to future research requirements of your Department?

(b) As a senior Federal scientist, how feasible do you think it is for the Foundation to attempt a "balance wheel" function in the Federal support of different fields of science?

(c) Has it succeeded in biology?

5. (a) Funds provided by the National Science Foundation have materially stimulated basic research and permitted a rate of growth

which would not have occurred otherwise. This can to some extent be viewed as the rim of a "balance wheel," in which our mission-oriented research program needs is the hub of the wheel.

(*b*) We do not view the primary function of the Foundation as essentially a "balance wheel" rather it is one of insuring an adequate total research program with major emphasis on non-mission-oriented basic research.

(*c*) Experience in the biological field tends to substantiate the above point.

6. Although the Department of Agriculture lacks authority to make training grants or to award fellowships, it has succeeded in training many young people in the agricultural sciences. How has this been done? What conclusions would you draw from this experience which are relevant to the Foundation's educational programs?

6. Research grants made by this Department have assisted in graduate training mainly because State experiment stations and other grantees make extensive use of graduate students as research assistants. Recent estimates show close to 2,000 graduate students being employed as research assistants under the match grant. This amounts to 8 or 10 percent out of the total grant. A fellowship program to bring the graduate student through the novice stage would greatly enhance the research assistantship program.

7. How does the Department coordinate its educational support with the National Institutes of Health, NASA, the Atomic Energy Commission, the Office of Education, and other Federal agencies that are concerned?

7. Since the procedure described in No. 6 constitutes the only educational support in USDA, it has not created a serious problem in coordination with other Federal agencies providing extensive support for higher education.

8. In supporting science education over the humanities or one field of science more than another, does the Federal Government incur an implied obligation to provide employment in the future for those graduates which it has supported? Do the students incur any implied obligation to stay in the field or to work on federally funded programs?

8. In our judgment the fact that the Federal Government provides support for science education ought not imply an obligation to providing employment in the future for graduates which it has supported. We strongly suspect, however, that students incur an implied obligation to stay in the field from which they receive Federal educational assistance. It is for this reason that the Department feels handicapped for the lack of any authority for fellowships and traineeships.

9. The original land-grant colleges were intended to foster both the agricultural and the mechanical arts. What would be the advantages and disadvantages of institutional grants, similar to those for agricultural research, to land-grant colleges to strengthen them as centers of modern technology? How could such a function be linked to the establishment of technical information centers under the pending State Technical Services Act?

9. With the rapid growth in the total support for research in the past 15 years, we question the need for specific support of centers of

modern technology through statutory institutional grants if a way can be found to assure that there will be a desirably wide geographic distribution of research grants under existing authority. Perhaps new authority in this area is the only way to meet the have-not situation and assure the desirable spread in geographic base.

10. To what extent does the Department of Agriculture furnish information on its research to the Science Information Exchange? What use does the Department make of the information collected by the Exchange? What has been the quality of this experience?

10. This Department provides full information on its research, both in-house and extramural, to Science Information Exchange. The Department has made only limited use of the information collected by the Exchange but is pleased with the quality of responses to our requests, particularly in biological fields.

11. In terms of upgrading the research understanding and capabilities of faculty of smaller colleges, do you think it feasible for the Foundation to consider an extension service through which competent scientists could visit, counsel, and assist other scientists in planning and carrying out their work and, in doing so, to also upgrade the quality of scientific research?

11. We foresee a need to assist in the upgrading of the quality of scientific research among the faculty of smaller colleges through counseling service, institutes and by other means. We seriously question the desirability of naming this function "an extension service."

12. The subcommittee has heard convincing testimony that the coming years will open a new age for applied biology. Assuming this is so, what should be the future relationships and responsibilities of the Foundation, the National Institutes of Health, and the Department of Agriculture for the support of biological research?

12. We foresee an increasing need for a close working relationship with the National Science Foundation and other Federal agencies engaged in biological research, particularly National Institutes of Health but including U.S. Department of the Interior, Atomic Energy Commission, Department of Defense, and National Aeronautics and Space Administration. The Office of Science and Technology can be very helpful in the establishing of interagency committees and task forces as mutuality of interest indicates to be necessary. Frequently the agencies concerned will formally establish work groups as illustrated by our present Interdepartmental Committee on Pesticides. Other current problem areas involving good interdepartmental cooperation include aflatoxin, leukemia, tobacco, and health, and water pollution. By appropriate use of interagency planning bodies, the mission-oriented agencies and the National Science Foundation each can delineate its appropriate role in the overall effort.

13. The point has been brought during the hearings that certain research projects are referred to NSF by other Government agencies. This raises the question of how one determines if a certain research project should be funded, say, by agency X, agency Y, or both. Specifically:

(a) What guidelines or criteria has Agriculture established to aid contract or grant administrators in determining if a certain research project is, or is not, within the purview or scope of the

Department's jurisdiction and, therefore, should, or should not, be supported?

(b) If written criteria have been established by the Department, please submit a copy thereof to the committee.

13. This Department does not have written criteria to be used in determining whether research proposals are, or are not, within the scope of the Department's jurisdiction. We do, however, give careful consideration to any given proposal to determine Department consensus, or jurisdiction based on the general mission of the Department. More specific criteria are being developed as part of a long-range study of agricultural research in which we currently are engaged.

APPENDIX 3

PREPARED STATEMENTS

STATEMENT SUBMITTED TO THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT OF THE COMMITTEE ON SCIENCE AND ASTRONAUTICS, HOUSE OF REPRESENTATIVES, BY LEE A. DUBRIDGE, PRESIDENT OF THE CALIFORNIA INSTITUTE OF TECHNOLOGY, JUNE 22, 1965

Gentlemen, I welcome this opportunity of submitting a statement to the Subcommittee on Science, Research, and Development relating to the work of the National Science Foundation.

I speak on this subject with a background of two kinds of experience:

(*a*) I served as a member of the National Science Board for 10 years—from 1950 to 1954, and from 1958 to 1964. I was Vice Chairman of the Board from 1962 to 1964.

(*b*) I am president of the California Institute of Technology, an institution which has many scientific research projects supported by the National Science Foundation and which has been the educational home of many students who completed their undergraduate work here and then went on to other institutions with NSF fellowships—as well as being the chosen institution for the residence of many NSF predoctoral and postdoctoral fellows.

I should like to begin by expressing my opinion that the National Science Foundation is one of the most important agencies ever created by the Congress of the United States. It is hard to see how the United States could have risen to and maintained its present position of world leadership in the field of science without the National Science Foundation. It seems clear that maintaining this position in the future will be even more dependent upon the work of NSF and its understanding support by the Congress.

Although a number of Government agencies participate in the support of scientific and engineering research in universities throughout the country, the NSF still occupies a unique position in this area. The other science-supporting agencies are "mission oriented" and are charged with supporting those areas of research which are either in the near or long term related to various missions.

However, the broad field of science is not covered by mission-oriented support since many important areas of research cannot be clearly identified with these various missions. It has been precisely one of the great values of NSF that it has been able to support basic

research on a broad front without regard to visible or immediate practical applications. Nevertheless, many practical applications have emerged from the work of NSF, and its research support includes many areas of great value to the national interest.

In addition to its research support, NSF has played a critical role in advancing our programs of higher education for scientists and engineers. Without the NSF fellowship programs, the number of scientists and engineers trained in this country in recent years would have been very much smaller, and our scientific leadership thereby would have been impaired. The excellence of our educational programs has been substantially enhanced both by aiding the universities to enlarge their facilities and their research activities in which graduate students participate, and also by making it possible for many graduate students to pursue advanced educational programs which would have been beyond their financial means had NSF fellowships not been available.

The basic policy which has guided all of the activities of the NSF, and which should never be abandoned in its future work, is that of the support of excellence. The NSF seeks to support excellence wherever it may be found. It supports those research projects judged by committees of experts to be of the very greatest promise in producing new knowledge, and it awards fellowships to those students (predoctoral and postdoctoral) whose records and achievements indicate high promise that they will become productive scientists in the future.

It is of the greatest importance that the Congress impose no limitations on the activities of the NSF which will interefere with its policy of the support of excellence. The great advances in science come not from the mass efforts of large groups of mediocre people, but from the imaginative leadership and ideas of a relatively small number of individuals. The NSF should seek out these highly competent individuals wherever they may be found and provide them with the facilities and staff to pursue their productive work.

As we look to the future, there are several areas of NSF activity and policy which I should like to discuss which will require full understanding and support by the Congress:

1. BASIC RESEARCH IN UNIVERSITIES

In spite of the rather large and widely advertised expenditures under Government grants and contracts for certain areas of research (space, defense, biomedicine, atomic energy, etc.), the fact remains that the total funds available for basic scientific and engineering research in universities are still inadequate. Many important fields are still hard pressed for adequate support. The rising costs and need for facilities in optical and radio astronomy justify very substantial increases in support during the coming years. Similarly, in chemistry, in solid state and low-temperature physics, in geophysics, and in a number of areas of basic research in applied science substantial additional funding will be needed over the coming years. The NSF funds for basic research grants to universities should be doubled in not more than 5 years.

2. NATIONAL RESEARCH CENTERS

The continued support of the national research centers in astronomy, radio astronomy, atmospheric science, plus the continuing support of special projects, such as those in oceanography, the Mohole project, etc., should not be confused with the general support of university research. These national projects should continue to receive the increasing support required to maintain their excellence and viability. But this should not be at the expense of the research grant budget. Some of these special enterprises, such as the NCAR Laboratory at Boulder, are just getting underway and will need considerably increased support during coming years to reach the level of activity and effectiveness originally visualized. Large capital expenditures will also be needed at the astronomy and radio astronomy centers at Kitt Peak and Green Bank, respectively. Every effort should be made to meet the required budgets of these important national activities during the coming years.

3. PREDOCTORAL AND POSTDOCTORAL FELLOWSHIP PROGRAM

This has been one of the most valuable of all NSF activities. It has helped greatly to encourage able scientists and engineers to pursue their graduate and postdoctoral studies. It has enhanced the ability of universities to accommodate more students and to improve the quality of their education. These programs are well established and face only two problems during the coming years:

(*a*) To increase the total fellowship funds as educational costs rise and as the total graduate student population rises. It would be desirable to maintain NSF fellowships for approximately the same proportion of all graduate students as at present.

(*b*) To impose no restrictions which would preclude the award of all fellowships on a straight merit basis. Artificial and unrealistic geographic restrictions are not in consonace with the national interest, which should seek to support the best and most promising students wherever they are found. This policy has already resulted in a most equitable national distribution, and restrictions imposed for political reasons would be damaging to the program and against the national interest.

4. THE PAYMENT OF "FULL" COSTS OF UNIVERSITY RESEARCH PROJECTS

It is encouraging to note that the Congress is apparently eliminating the unrealistic limitation in the payment of "indirect" costs to a maximum of 20 percent of direct costs. These indirect costs are just as real as the direct costs, and the failure of Congress to allow the indirect costs to be fully covered in university grants has resulted in heavy burdens on colleges and universities throughout the country who are energetically seeking to enhance and improve their research activities because of their contribution to the national interest. It is hoped that all agencies administering research grants will be freed to pay full audited indirect costs in accordance with polices and procedures which have already been established in connection with research contracts by the Bureau of the Budget.

In connection with this matter, there has, however, been a misunderstanding about the desirability of a university "participating" in the support of research. Of course, the university should "participate"; but what is often overlooked is that the university inevitably and automatically participates. To be a center for basic research at all, a university must have built its plant and acquired the staff for both its educational and research enterprises. No university research project exists in a vacuum. It must be a part of an on-going institution which has graduate and undergraduate students, which has a physical plant, library facilities and a well-rounded faculty covering all appropriate academic fields of knowledge.

Even when the identifiable direct and indirect costs of a particular research project are covered by a Government grant or contract, this project still depends upon the total university environment in order to exist and be effective. Only a very few American universities which have given great emphasis to research find that their Government support of research equals as much as half of their total annual budget. For most institutions the percentage is very much less. And yet the total activities of the institution contribute to every single research project—even including those expenses directed primarily at instruction, since education and research are so intimately tied together in a university, each supporting and improving the other. All universities are hard pressed to maintain their total programs and to maintain the strength required to support those research activities which are deemed worthy of Government assistance. Hence, in identifying the university "participation" one must examine the entire program of a university and note what a very large fraction of this total program comes from the university's own private (or State) sources. The policy of the Government should be to enhance the strength of the total university operation and not insist on the diversion of funds from hard-pressed budgets to pay out-of-pocket costs connected with research projects which, in the judgment of the particular Government agency, are deemed worthy of support.

I very much trust that the Subcommittee on Science, Research, and Development will set forth, most emphatically, the enormous value of the National Science Foundation to the national interest and to the progress of our civilization, and will strongly advocate continued understanding and financial support of the National Science Foundation programs.

STATEMENT OF THE AMERICAN INSTITUTE OF ARCHITECTS BEFORE THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT, COMMITTEE ON SCIENCE AND ASTRONAUTICS, HOUSE OF REPRESENTATIVES, JULY 28, 1965

I am Benjamin H. Evans, AIA, an architect and director of research programs for the American Institute of Architects. This testimony was to have been presented by Mr. William H. Scheick, FAIA, executive director of the institute, who could not be present due to an unavoidable commitment.

Before assuming my position with the institute, I was head of the architectural research group at Texas A. & M. University and associate professor of architecture. My experience includes teaching, research, private practice, and consulting work for over 150 architectural and industrial firms. My advice to the American Institute of Architects on building research is based on this experience. Nevertheless, the following statement is not personal, but reflects the attitude of the American Institute of Architects Committee on Research for Architecture, and the institute.

I appreciate the opportunity to appear before you to discuss the National Science Foundation and its relationship to what I call the building construction sciences.

The National Science Foundation has, of course, played a vital role in developments in science and technology in this country during the past 15 years. However, its involvement in the building sciences specifically has been limited. The American Institute of Architects and the National Science Foundation have had excellent relationships through the years and several fundamental projects in the architectural field specifically have been supported by the Foundation. Admittedly, the number of projects supported in architecture, building science, and the related areas has been comparatively small. But it is our hope and expectation that projects in these areas can be increased considerably in the ensuing years. Let me explain briefly why we think there is a serious need for greater National Science Foundation activity in these areas, and describe the kinds of projects with which we are concerned.

It has been said that more buildings and structures will be built in the United States in the next 40 years than have been built since the beginning of our country. Such an expansion of construction will be necessary to meet the needs of the rapidly expanding population. The problems of planning, constructing, coordinating, and administrating our rapidly expanding urban areas are well known to most of us. The problems of blight, poverty, and ugliness, of the serious lack of open spaces, recreational areas, and transportation, are known to most of us. Such conclusions indicate that considerable intelligence and effi-

ciency will be required in solving these expanding problems—economic, social, and technological.

There are many areas of fundamental knowledge in each of these fields that have yet to be thoroughly explored. At our current rate of attack on these problems, the answers will come too late. They are too late already. If we are to be prepared for the job that lies ahead, more attention must be applied.

Much research is being done and has been done, of course, which will contribute significantly to the solution of these problems, but the concern here is with the rate at which problems are being attacked.

There are three aspects of the situation that need attention. First, there is the need for more concern by the Government for assuming a vital role in an area which needs attention and which promises such significant benefits for the public. Second, there is the need for more highly qualified people to do research in these areas. Under the present state of conditions, our brightest young men are not being attracted to the building science areas, but to areas of science which are more exotic, such as in the physical science (electronics, space exploration) and where there are more significant programs of science with greater and more stable financial support. Third, there is the need for more extensive research programs at the universities which deal with the problems of man's built environment, particularly in architecture, planning, landscape architecture, and the allied engineering fields. There is a need for stimulation of a greater emphasis on building research in the professional curriculums and on building research programs at the graduate level.

This leads to the conclusion that NSF, as the cornerstone for scientific development in this country, should increase its efforts in the development of institutions and programs for the building sciences, in addition to increasing its support of specific scientific questions related to the building sciences and the problems of the urban society.

I suspect that the definition of science as used by NSF tends to be too restrictive. There should be greater concern with the science of people and their behavior, with the interaction of people with their environment, and with society and the problems of providing adequate and appropriate shelter, transportation, communications, disposal systems, power supplies, and so forth.

These problems are not uniquely the province of the architects or of the others intimately involved in the building sciences. It is in many respects, the problem of all disciplines and every citizen. However, the architect, the planner, the landscape architect, the allied engineering specialists, all have fundamental and unique contributions to make and certainly will add breadth and depth to the development of knowledge about communities, cities, and their people.

So, then, new ways must be developed to stimulate and support research into scientific problems that underlie the human, technological, and environmental areas of the urban society. These studies can most logically be carried on at the universities, where qualified personnel are most likely to be found and where students will be attracted to the field. But stimulation of activities here will require not only a more intensive effort within the National Science Foundation, but it will also require leadership from NSF, since there are too few people working in these areas now to keep up with the demand for new knowledge.

In 1959, the National Science Foundation, through a grant to the AIA supported a Conference on Basic Research in Architecture at Ann Arbor, Mich., to which scientists from many disciplines were invited. For 2 days and nights they explored areas of concern.

Among the types of problems which that conference pointed out as essential for exploration—and which the AIA feels are appropriate for NSF support—are the following: studies to determine more completely the effects of environment on human beings; the reactions of people to sound, heat, odor, color, texture, light, the geometry of space, and so forth—the psychological reactions as well as physiological reactions; studies of the economics of land acquisitions, systems of building construction, land utilization, labor utilization, space design, mechanical systems, and so forth; studies to develop technological innovations in structural systems, power supply systems, environmental controls, space enclosures, communications systems, and so forth. This does not, of course, include the development of products and materials that have proprietary interests.

Such a list could be extended almost indefinitely, but these few points indicate the broad scope of activities in the building sciences which might legitimately receive NSF support, and which under present conditions are developing much too slowly.

Another pressing concern has to do with the proposed National Foundation for the Arts and the Humanities. While I have discussed here the building construction field as it is related to scientific activities, there is also that side which deals with the arts and humanities. The AIA supports the development of the Foundation for the Arts and the Humanities and sees it as helping to balance Federal support in science and technology. It is important to recognize the need for activities in both areas, since building is both an art and a science. This also points up the need for some clarification of the respective roles of the Foundations and the need for cooperation between them. We take cognizance of the letter, which is attached to this statement, from Prof. Burnham Kelly, AIA, dean of the College of Architecture at Cornell University and a member of the Commission of Fine Arts, to the Honorable Adam C. Powell, regarding the importance of good relations between the Foundations.

In conclusion I reiterate the urgent need for more fundamental research dealing with the many and broad aspects of architecture and building science. Such research activities must be stimulated by a greater awareness of the need for further scientific study, by the development of more institutions to conduct scientific research, by the encouragement and development of more scientific personnel, and through the application of more funds to such studies. We believe the National Science Foundation is the logical and appropriate place for such activity and leadership.

COMMISSION OF FINE ARTS.

HON. ADAM C. POWELL,
House of Representatives,
Washington, D.C.

DEAR MR. POWELL: As a member of the Fine Arts Commission and as dean, College of Architecture of Cornell University, I feel compelled to address this letter to you.

It has been the intention of Congress to establish new foundations to serve the areas of the humanities and the arts which have been notably neglected in the past in favor of such disciplines as medicine and the sciences. As Congress

deliberates this move it is its intention to avoid duplication in the functions of such foundations. This is understandable; however, it is important to recognize that broad disciplines cannot be easily assigned to one or another of such foundations, and that particularly some of the most important professions such as architecture may very well be completely neglected because of the tendency of each of the foundations to say it properly belongs to one of the other.

In the healthy development of the profession of architecture, it may not only be possible but absolutely necessary to have in simultaneous operation a study of some aspect of science and technology under the Science Foundation; a study of some aspect of human social relations under the Humanities Foundation; and a study of some aspect of design and the arts under the Arts Foundation. Architecture cannot fulfill its function and its public mission if it cannot operate in all three areas at the same time. In fact, of course, it does.

The experience of the profession of architecture has been that foundations and other sources of support tend to regard it as an anomaly and not easily classified and therefore it tends to be excluded from each office to which it applies. If this is done in the new foundations, the Government is unduly penalizing the architectural profession because of its comprehensive point of view. The reverse should be true. The interest of the public is very strong in having a profession which does attempt to synthesize and analyze the scientific, humanistic, and artistic disciplines for the enhancement of the natural and manmade environment of our citizens.

Sincerely,

BURNHAM KELLY, *Vice Chairman.*

STATEMENT PREPARED IN THE DEPARTMENT OF AGRICULTURE IN RESPONSE TO THE JUNE 9 MEMORANDUM FROM CONGRESSMAN EMILIO Q. DADDARIO, CHAIRMAN, SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT, IN CONNECTION WITH ITS REVIEW OF THE NATIONAL SCIENCE FOUNDATION, BY DR. NYLE C. BRADY, JULY 29, 1965

INTRODUCTION

On behalf of the Secretary of Agriculture and his staff, I express our appreciation for the opportunity afforded for us to participate in the comprehensive review of the National Science Foundation.

During the 15-year history of this well-conceived institution, it has grown steadily in stature and has established itself as an essential element in the science structure of the Nation.

The Department of Agriculture, being strongly mission oriented, has encouraged, sponsored, and supported basic research to the limit of its capability. At the same time, it is completely sympathetic to the goals of the National Science Foundation, recognizing that it has and will continue to play a unique role in giving greater purpose and direction to the Nation's total basic research effort. In so doing, we see no curtailment of opportunity for the support of basic research in our Department, or in other mission-oriented scientific establishments, in or outside of Government.

BENEFIT TO ALL GOVERNMENT AGENCIES

The Department in common with other departments and agencies of Federal Government has benefited from the outset by the programs carried out by the National Science Foundation. Its program for support of basic research and supporting facilities has greatly stimulated the program of basic research beyond that which would have been accomplished through the regular programs of the mission-oriented agencies.

Nonprofit agricultural research institutions have shared in National Science Foundation grants for basic research from the beginning of its research grant program. Scientists at the State agricultural experiment stations have consistently been awarded 2 or 3 percent of the total grants for the basic research made each year by the Foundation. Also the Foundation's support for research facilities at many of the land-grant universities, particularly those for biological research, have been of great value in permitting a more comprehensive research program in this area.

The Foundation's support of science education programs also has become a major factor in stimulating a continuing supply of well trained young scientists. This Department, lacking any legal authority for fellowship or trainingship programs, has particularly looked

to the National Science Foundation to provide the incentives and the financial assistance so essential to encouraging graduate training in the many disciplines essential to the continuing sound program of agricultural research.

This Department views with some concern the lack of uniformity among the major research agencies of Government to the support for science education. We suggest that authority in this field be extended to all interested mission oriented research agencies or that it be centralized in the National Science Foundation.

Other aids to education, particularly the institute programs, have had a major impact on improving the quality of science instruction in the Nation's secondary schools. We have viewed with interest the recent efforts to expand the institutional science programs supported by the National Science Foundation. This Department is highly sympathetic to this objective since our long history of institutional support for agricultural research in the land-grant colleges and universities and the resulting growth of centers of recognized merit in every State gives support to the soundness of this program. The direct support to enhance science facilities for graduate training in many institutions is also proving its worth.

The Department also strongly endorses the support for science information services which in recent years has become a major part of the Foundation's program. The National Agricultural Library has worked closely with the Office of Science Information of the National Science Foundation since 1958 when NSF began its expanded interest in governmental activities in the science information field.

The National Defense Education Act of 1958 which established the Science Information Service included a "Science Information Council" to be composed of leaders in the fields of librarianship, scientific documentation, the sciences and the lay public. The Director of the National Agricultural Library has served as an ex officio member of the Council since its establishment. Members of the library staff have served on various committees set up by OSIS in the field of librarianship, documentation and coordination of library activities.

Direct support was furnished by the National Science Foundation to the National Agricultural Library in 1961 for the study and evaluation of the need for an oriental division in the library. Support was provided on a 2-year basis and enabled the library to assess its oriental holdings which had been built up over a period of a hundred years. The study indicated an urgent need for special attention on the part of the library to its oriental materials. A section was established by the library to handle these publications and this is now being carried on as a regular library activity.

There have been no areas of joint support for research, although the library has provided advice on various programs which were under consideration by NSF. In addition, research studies conducted by or through NSF have been of value to us. An example is the current study of journal literature.

From close working relationship with NSF we are convinced that it does perform a very important function in coordinating activities in the science information field and in providing a base for research in the documentation and science information area. There is a need for further clarification of the responsibilities of NSF in the science

information field. During the past 7 years there have been many changes in the programs and objectives as well as the responsibilities of the Science Information Service. It would be helpful to all Government agencies if a long-term policy could be established for the Office of Science Information Services.

We have followed with a great deal of interest the evaluation of the mechanism for science policy planning in the Federal Government. We recognize that responsibility originally assigned to the Foundation in its basic legislation "to develop and encourage the pursuit of a national policy for the promotion of basic research and education in the sciences," posed a very difficult problem for an agency which also had major operating responsibilities. In our judgment, the transfer of much of the national policy and coordinating responsibility to the Office of Science and Technology has made the Foundation much more effective in its major areas of activity as discussed above.

We particularly commend the Foundation for the comprehensive surveys which it makes of the research and development effort of colleges and universities and other nonprofit institutions and of industry. Also, we have been an enthusiastic supporter and user of the annual summary of Federal funds for science. The flow of information from these surveys by the Foundation is of inestimable value in sound research planning for the Nation.

NSF–DEPARTMENT OF AGRICULTURE RELATIONSHIPS

The Department agencies having a major responsibility for agricultural research have shared many problems with and derived many direct benefits from the NSF.

Cooperative relations between the Forest Service and the National Science Foundation are largely associated with a program of study, research, and evaluation in the field of weather modification. Since 1960, NSF has given direct support amounting to $344,000 to our Forest Fire Laboratory, Missoula, Mont., to carry out investigations in the general area of weather modification as related to forest fire control. In addition, our Director of Forest Fire Research participates in the NSF Interagency Committee on Weather Modification. The Forest Service also prepares information annually for the NSF report on weather modification. At the request of NSF, forest fire research scientists assist in the review and prepare recommendations on proposals for basic fire research. At the invitation of NSF, forest fire research scientists participate in special symposiums and conferences on atmospheric sciences. Three examples of such participation during the current year are the NSF symposium on mathematical models and statistics in weather modification; NSF symposium on the economic and social aspects of weather modification; and the Conference of the NSF Weather Modification Commission. The Foundation has done a good job in monitoring and coordinating national research efforts in the areas of atmospheric science and weather modification research and has given excellent support to this program.

Cooperation in other areas of forestry research has been somewhat more limited. The Division of Watershed, Range, Wildlife Habitat and Recreation research has provided specialists for reviewing and evaluating grant proposals for both the Regulatory Biology and the

51-204—65—vol. II——36

Environmental Biology Branches of NSF. This is to continue at the request of NSF.

Of considerable significance is the NSF support of basic forestry grants at institutions of higher learning amounting to $1.4 million in fiscal year 1965. This may be compared to the Forest Service grants program, including both Whitten Act (Public Law 84–473) and basic research (Public Law 85–394), amounting to about $1 million in fiscal year 1965. It is apparent that the NSF grants add strength to the Nation's forestry research program at various universities.

The Agricultural Research Service has shared with the Foundation the sponsorship, planning, and joint financing of many interesting projects over the years. These include such undertakings as:

Symposium on Radioisotopes in the Biosphere.
Fifth International Congress on Nutrition.
Symposium on Mutation and Plant Breeding.
Symposium on Statistical Genetics and Plant Breeding.
Symposium on Plant Pathogens in Soil.
XVIth International Congress on Zoology.
31st Meeting and Congress of the International Federation of Documentation.

The Department is cooperating with the Foundation on the translation of scientific articles and books originating in Russia, Poland and Yugoslavia. To facilitate this program, the Department has transferred to the Foundation during each of the last 2 years the equivalent of $100,000 in Israeli pounds. This program is authorized under Public Law 480, section 104K. The foreign currency available to the Department appropriations comes from the sale of surplus agricultural commodities for the currency of the country. The special foreign currency funds available to the Department are appropriated by Congress. Under this program many useful East European articles dealing with agricultural research have become available for our scientists.

Based on cooperative experiences the administration of the Agricultural Research Service has placed particular emphasis on two major purposes which the NSF has served in Government:

(1) To provide an avenue of support of the scientific disciplines in American science without regard to the missions of the other Government departments. This has contributed in a major way to increasing the fund of knowledge and the pool of competent scientists from which Agriculture, among others, draws for its personnel.

(2) To function in effect as a "national science contingency fund" to assure prompt attention to important emerging problems in science prior to the time that the "line" agencies of Government can provide appropriate attention to these problems through the budget process. The capacity of the NSF to perform vital functions of this type should not be impaired.

The Cooperative State Research Service, the Department agency charged with the administration of the statutory grants to State experiment stations and related research grants, has cooperated closely with the Foundation in strengthening the programs of these nonprofit research institutions. The support made by the Foundation to programs of basic research in these institutions has strengthened

the base for the total program of agricultural research and at the same time has attracted many graduate students, serving as research assistants to training in those disciplines so essential to a sound program of agricultural research.

In this connection, the special development programs of NSF is particularly noteworthy. This program to identify and support the development of centers of excellence in science in all areas of the United States has great potential and inevitable impact on the mission-oriented research of the Agricultural Experiment Stations, themselves centers of excellence in agricultural research in varying degrees. We shall try to be fully informed of status of this program and seek in appropriate ways to enhance the capacity of the land-grant universities of which the respective SAES are a part, to qualify as centers of excellence in areas of science relevant to agriculture, especially in the social sciences which are inadequately supported.

In conclusion, we wish to reiterate our belief that NSF is filling and should continue to fill a highly important role in the development and presentation of a national science program. We look forward to further effective cooperation with the Foundation in the strengthening of this program.

STATEMENT OF DR. JOHN W. GARDNER, PRESIDENT, CARNEGIE FOUNDATION, BEFORE THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT OF THE COMMITTEE ON SCIENCE AND ASTRONAUTICS. AUGUST 3, 1965

I want to talk about the relationship between the National Science Foundation and the universities.

When Representative Daddario asked me to testify, he suggested that I might wish to comment on "the relationship, current and potential, between the National Science Foundation and private foundations." I have given a good deal of thought to the matter, but I must say candidly that in my judgment that relationship will not shed much light on the problems of the National Science Foundation and its future. At the time the National Science Foundation was created, the great private philanthropies of this country provided an important model for the new agency. The very word "Foundation" in its title reflects that fact. The relationship the National Science Foundation maintains with its grantees, and many of its other procedures and policies were pioneered years earlier by private philanthropy.

But, generally speaking, the time when the National Science Foundation had major lessons to learn from private philanthropy is past. The National Science Foundation has done its own pioneer work in the field of giving, and many of the private foundations would profit by closer examination of that work.

The other question of interest is whether we should look toward some division of labor between public and private programs in support of research and teaching. One hears it said that when public money comes into a field, private money leaves that field. This suggests to some people that public money should stay out of certain fields altogether. I would have difficulty accepting any such solution, but I cannot deny that the problem is real. The best that can be said is that we are all still groping toward an answer—and, of course, there may be no tidy answer.

So now, Mr. Chairman, with your permission, perhaps we may turn to a matter on which I can express more definite views—the relationship of the National Science Foundation to the universities. To state the problem more broadly, I'm concerned about the relationships of all Federal agencies with non-Federal educational and research organizations (private and public colleges and universities, independent research organizations, libraries, and so forth).

This is a part of the larger question of the role that Government is to play in our society. It is a question that every intelligent citizen has worried about. One hears it said that Government is gaining increasing dominance in our lives and that the private sector is losing ground. Is that true? One hears it said that the Federal Establish-

ment is becoming all-powerful, at the expense not only of the private sector but of the State governments. Is that true?

One encounters extreme proponents of one outcome or the other. Some are pathologically afraid of big government and would like to diminish the governmental role almost without limit. Others are just as extreme in their advocacy of doing everything through the Federal Government. For my part, I believe that the vitality and creativity of our society will best be served by maintaining the vigor of both governmental and nongovernmental sectors. I certainly do not wish to see excessive centralization of power. But some of our shared purposes can be advanced only through action of the Federal Government.

We face an array of pressing problems. In many cases the old methods and instrumentalities for solving those problems are no longer adequate. We Americans are nothing if not purposeful, and when we can't solve our problems by the old methods we are going to try new methods. Despite the fact that few of us really want to enlarge government, we have seen, in recent years, the emergence of many governmental functions which one would not have dreamed of a generation or two ago.

I was greatly encouraged by the fact that the Federal Government, beginning with World War II, and continuing through the 1950's, developed an enormous range of contractual relationships with nongovernmental organizations and agencies. These encompassed not only defense contracts with industry but relationships with universities and independent research laboratories. It seemed to me that in the great flexibility of the contract and grant relationship, the Government had hit upon a significant way to accomplish public purposes without the endless enlargement of the Federal Establishment. It was clear that such contracts and grants, properly used, could further the shared purposes of the American people. And at the same time they could strengthen the nongovernmental institutions that have contributed so greatly to the richness and diversity of our social processes.

Of course, we all know now how very complicated those contract and grant relationships can be. In the case of the industrial contracts, some Government people honestly believe that industry has grown fat at the Government's expense. In contrast, many in industry today are saying that the screws have been so severely tightened on contract relationships that the industrial contractor has become, for all practical purposes, an arm of the Federal Government. According to a third view, gloomier perhaps than either of the others, industry is not bilking Government nor is Government dictating to industry, but the two have entered into an unholy alliance at the expense of all the rest of us.

I take still another view. I believe that the Government-industry contract presents inherent difficulties but also great benefits for both sides; and I believe that with patience, imagination, and statesmanship, the benefits can be maximized and the difficulties reduced (though never to zero).

I take the same view of the relationship between Government and the universities. The partnership can be an exceedingly fruitful one despite its complexities.

An understanding of the complexities cannot be arrived at if we insist on clinging to old cliches and categories. In this connection I should like to quote from a speech I gave on the subject last year.

Do the emerging relationships with the universities and with industry represent an increase in Government power or a decerease? A centralizing trend or a decentralizing trend? When one considers that many industrial concerns and universities are now, in some measure, dependent on Government support, one is inclined to see the new trend as a growth in Government power. But to the old-line Federal official, used to a world in which Government funds were spent for purposes defined by Government and administered by hierarchically organized departments under complete Government control, the new trend looks like a grievous loss of Government power. He can't appraise what it is doing to industry and the universities, but he knows that it is having a profound effect on Government. Wherever he looks, he sees lay advisory bodies recommending how Government money should be spent, and nongovernmental organizations spending it. Both industry and the universities spend their Government contract money to outbid Government in hiring of scarce personnel. The universities, particularly, insist that the money be spent in ways that they themselves define, and they do not welcome the advice of well-meaning Government officials. It is difficult for the Federal official to observe all this and feel that his power is growing.

The new partnerships cut across the old public-private categories as well as the old centralization-decentralization categories. A new sort of relationship has been created and we are going to have to judge it by new criteria. Furthermore, it is a relationship that it still evolving, so we still have a chance to shape its future course.

In the same speech I commented on the nature of the tensions between Government and the universities:

When Government agencies and universities work together, there are predictable sources of difficulty. The agency tends to surround the relationship with more and more defining conditions, until the university's freedom of decision is undermined. This does not reflect a sinister desire to diminish anyone's freedom. It stems from the nature of Government responsibilities and habits of mind. The remarkable thing is not that all agencies show these tendencies, which they do, but that some agencies have had the wisdom to curb them.

Just as the Government agency tends to tighten the defining conditions of the relationship, so university people seek to loosen them. They tend to push all contracts and grants in the direction of the general support grant—fewer conditions, more freedom to define objectives, and greater continuity of support.

Underlying these differing approaches is a fundamental difference of outlook on the issue of accountability. The accountability of the university varies, of course, with the various kinds of contracts and grants. In basic research grants it may be limited to the barest minimum of fiscal reporting, but in contracts it may be more complicated. It is not easy for university people to understand that the Government lives by accountability (and no one would wish it otherwise)—accountability to the taxpayer, to Congress, to the General Accounting Office, and to the White House. In most contract procedures, the Government agency has delegated some of its powers to a private organization. Naturally it tends to want to impose on that organization the same accountability it requires of itself. What it fails to understand, of course, is that excessive zeal in demanding accountability may create intolerable conditions for the universities with which it is dealing.

Just as the Government agency is often too rigid in demanding accountability, so the university is sometimes too careless. The university should sympathize with the Government's basic problem and should focus its criticism on those forms of accountability that are clearly inappropriate to a university. When it can serve the Government's requirements without damaging its own position, it should do so.

Now let me return to the National Science Foundation. Perhaps more than any other agency of Government it has sought to deal wisely and farsightedly with the universities. No one would pretend that it has escaped the complexities of the relationship or that it has been without fault; but it can be proud of its record. And it can serve as a

valuable model in the years ahead. A fruitful relationship between Government and the universities is essential to the continued creativity of our society. I say that with all the emphasis that I can bring to it. All departments of Government are going to have to deal eventually with the universities, independent research laboratories, and other nonprofit institutions. No department can any longer afford to be wholly cut off from the sources of new talent and innovative research. Some Government departments, having had little experience with the relationship, are fumbling badly in their dealings with the universities.

We are still in the process of discovering the forms and modes of relationship that will make creative partners of Government and the universities. No agency of Government is in a better position than the National Science Foundation to advance that process of discovery.

The aim is to give Government agencies access to the creative potentialities of the universities, and the universities access to the resources of Government. Conditions of the relationship must be so defined that irresponsible (or careless) elements in the university community will not show a wanton disregard for the taxpayer's dollar and, at the same time, that the responsible elements in the university community will not be paralyzed by Government redtape. The two objectives sometimes seem wholly incompatible. The faithful Government accountant builds a network of regulations to protect the taxpayer, and the university is imprisoned therein. We are far from having arrived at a stable and workable philosophy to govern the relationship. There have been regrettable examples of carelessness with Government money. But at the same time we must establish some limit beyond which the chasing of dimes in behalf of the taxpayer yields to a respect for university autonomy and the requirements of creative work. Innovative work is rarely done in the presence of an overeager accountant. The future is rarely shaped by men who are busy devising (or abiding by) foolproof regulations.

The National Science Foundation, like the National Institutes of Health, has come increasingly to view our educational system and our great universities as national resources to be preserved, strengthened, and developed. Increasingly, it has looked beyond the urgencies of the moment to the longer term needs of these institutions.

But though one must give the Foundation great credit for what it has done to date, it seems to me that it has barely scratched the surface. Our great universities are national resources of a very special kind. They are the creative sources of a complex technological society. The Foundation should think more systematically and more boldly about the long-term implications of that fact and the long-term strengthening of those institutions. And it must discover how to do this in such a way that the universities preserve their heritage of freedom. If it succeeds in this, it will have done the Nation an unprecedented service in planting the seeds of future greatness.

We are not in the habit of thinking nationally. We are not really a very planful people. But our society is now so intricately organized and interconnected, and the pace of history has so drastically quickened, that we have little choice but to look ahead more systematically than we have to date. If we do so, we shall see that there are great and exciting tasks to be accomplished. Through a wise and imaginative strengthening of the universities, we could begin today to create the foundations for a greater America for our grandchildren.

STATEMENT BY DR. ARTHUR F. SCOTT, PROFESSOR OF CHEMISTRY, REED COLLEGE, PORTLAND, OREG., TO THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT, HOUSE OF REPRESENTATIVES, AUGUST 4, 1965

The training of U.S. scientists at all levels of our educational system is currently under review and study. It is imperative that all facets of this exceedingly complex problem be illuminated and scrutinized because the conclusions to be drawn and the decisions to be made are crucial to the future development of science and technology in this country.

This memorandum is intended to throw light on certain aspects of the education and training of scientists at the undergraduate or college level. It presents a specific recommendation which, it is believed, will strengthen the training of scientists at the undergraduate level.

Specifically, this memorandum is concerned with three basic factors which, conceivably, may have some bearing on the accomplishments of an institution's baccalaureates. These basic factors are—

Type of control of institution (private-public).
Size of institution (large-small).
Resources or "strength" of institution.

HISTORICAL NOTE

For roughly 200 years, higher education in this country was the responsibility of private institutions, many of them church related. Around the middle of the last century, the traditional system began to change as the result of various social and economic pressures: instruction in science began to be accepted as a part of the undergraduate curriculum; certain institutions introduced graduate instruction and so became universities; and institutions supported by public funds appeared on the academic scene. By 1900 the system of higher education in this country had begun to take on the pattern that we know today.

In any review of this country's academic establishment it is important to keep in mind that the establishment is by no means a static one. During the past 60 years many changes have taken place. The notes to be presented in this memorandum will be limited to a discussion of the present status of undergraduate institutions which are responsible for the basic training of U.S. scientists.

SOURCES OF INFORMATION

The data to be presented in this memorandum come from a study by the writer, entitled "Education and Training of Chemists in the U.S.A." which was published as a four-part series this past spring in Chemical and Engineering News (C. & E. N.). The published data apply specifically to the 884 institutions that awarded a bachelor's degree in chemistry in 1962. However, since these same institutions are the ones that educate and train this country's other scientists (mathematicians, physicists, biologists, etc.), the picture derived for the training of chemists must be generally valid for the training of all scientists.

A further advantage in basing this presentation on information available for chemists is that the American Chemical Society has a committee on professional training which has the responsibility of identifying undergraduate institutions that have the resources (staff, curriculum, library, laboratories, and equipment) deemed desirable for the training of chemists. It is not unreasonable to assume that most of the institutions having resources adequate for the training of chemists also have the necessary resources for the training of other scientists. Accordingly, we shall hereafter refer to those institutions that satisfy the ACS criteria as "strong" and those that do not as "weak," intending these adjectives to refer only to the resources of an institution with respect to training in science.

CONTROL OF INSTITUTION

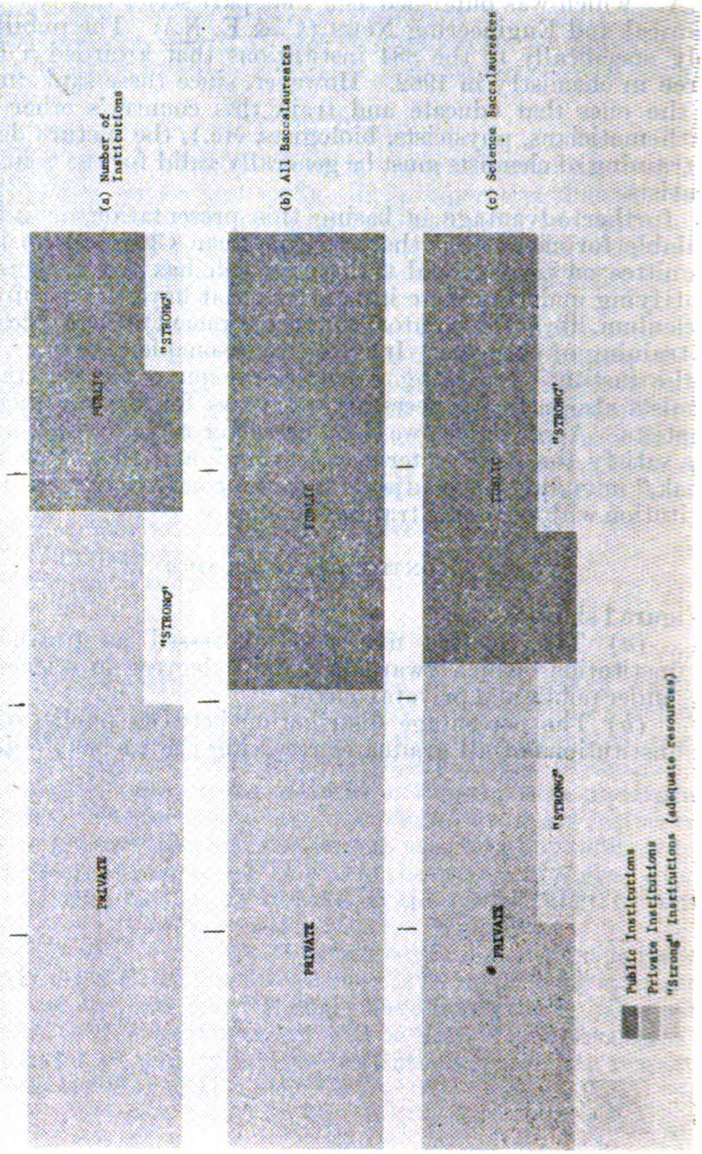
Figure 1 shows:

(*a*) The relative numbers (expressed as percentages) of institutions which award bachelor's degrees in science that are under public and private control.

(*b*) The percentage distribution between public and private institutions of all graduates receiving the bachelor's degree.

Fig. 1

Percentage Distribution, According to Control (Public and Private), of U.S. Colleges and Universities that Award Science Baccalaureates.



(*c*) The percentage distribution between public and private institutions of those students who were awarded the bachelor's degree in science (chemistry).

The data in figure 1 show clearly that, in spite of the tremendous growth of public institutions, the privately controlled institutions are responsible for about one-half of all bachelor's degrees and for slightly more than one-half of bachelor's degrees in science (chemistry).

One cannot compare directly the resources of public and private institutions because, as is evident from figure 1, both categories include "strong" and "weak" institutions.

One can, however, make a useful comparison of "strong" and "weak" institutions, disregarding the type of control.

From figure 1 we see that about 40 percent of all science (chemistry) baccalaureates are awarded by the "weak" group of schools, public and private combined.

It has also been shown (C. & E.N. article) that the fraction of the science (chemistry) graduates that continue their education in graduate school is essentially the same for the "strong" and "weak" groups of colleges.

Figure 2 presents information for academic institutions compared on the basis of size ("large" equals total enrollment greater than 2,000; "small" equals total enrollment less than 2,000). It shows—

(*a*) The relative numbers (expressed as percentages) of large and small institutions.

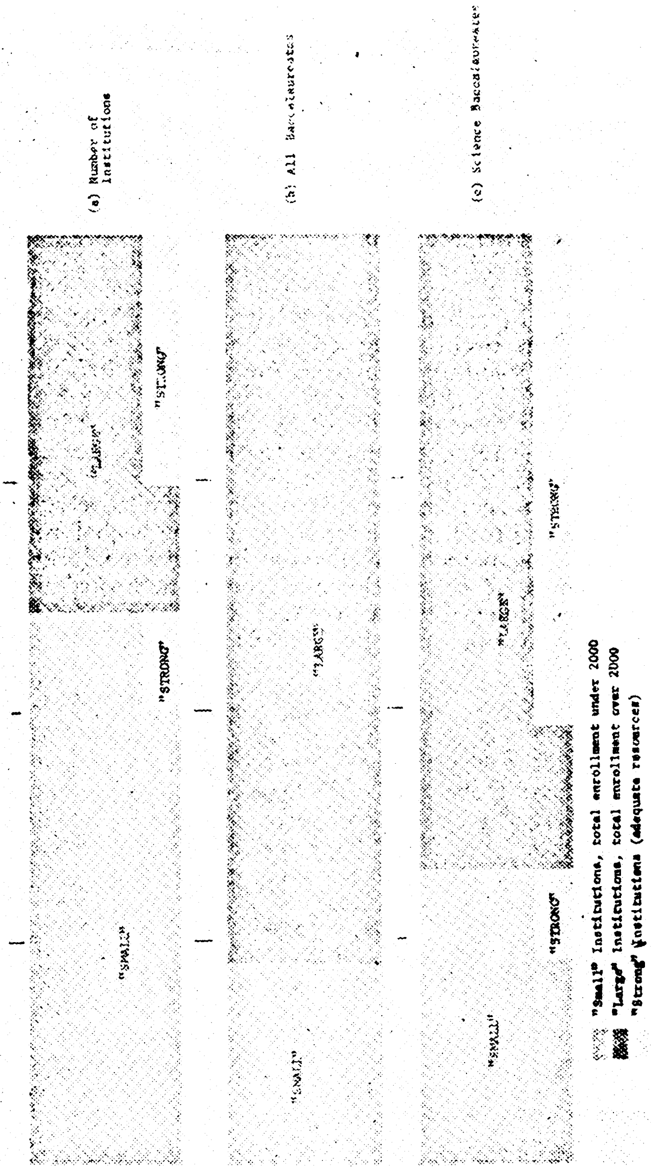
(*b*) The percentage distribution between large and small institutions of all graduates receiving the bachelor's degree.

(*c*) The percentage distribution between large and small institutions of those students who were awarded the bachelor's degree in science (chemistry).

As is at once apparent from figure 2:

Fig. 2

Percentage Distribution, According to Size of U. S. Colleges and Universities that Award Science Baccalaureates.



The percentage of small institutions is considerably greater than that of large institutions.

The percentage of all baccalaureates from large institutions overshadows that from small institutions.

The percentage of science (chemistry) baccalaureates from large institutions is just about double that from small institutions. It is to be noted, however, that the proportion of all graduates who take their degrees with a major in science is significantly greater for the small institutions than for the large institutions.

With regard to "strong" and "weak" institutions in relation to their size, figure 2 shows:

That a high percentage (66 percent) of the large institutions are in the "strong" class. This would seem to be a natural consequence of the fact that most large institutions are universities and one would expect them to be "strong."

That only a small percentage (17 percent) of the small schools are in the "strong" class.

That the small "weak" institutions provide about twice as many science (chemistry) graduates as the large "weak" institutions.

FURTHER NOTE ON RESOURCES OF U.S. COLLEGES AND UNIVERSITIES

In the preceding two sections, reference has been made to "strong" and "weak" institutions as determined by criteria set for college chemistry instruction. It is reasonable to suppose that the basic cause of the difference between "strong" and "weak" institutions is a difference in financial resources. In this section, attention will be directed to some dollar figures that lend strong support to this supposition.

The per-student educational budget of an institution can be calculated from published figures for "educational and general" expenses and the total enrollment of the institution. The per-student budget figures computed in this way cover an extraordinary range, from about $300 to $6,000, for both public and private institutions. A partial analysis of these per-student budget figures is presented in the following tabulation which shows the median figure for the specified categories.

Median per-student educational budget

	Private institutions	Public institutions
Classification of institution:		
Strong	$1,400-$1,600	$1,200-$1,400
Weak	800- 1,000	600- 800

This analysis could be improved if it were possible, in the case of universities, to distinguish between costs for undergraduate and graduate instruction. This is practically impossible and, therefore, the per-student budget figures for universities are the average for all students, undergraduate and graduate alike. Although it is recognized that the per-student budget figures for colleges and universities are not strictly comparable, they have been treated as if they are on the same basis in deriving the median figures given in the tabulation.

SUMMARY AND RECOMMENDATIONS

Summary

The salient points made in this memorandum, with certain supplementary comments, are the following:

> The small undergraduate college is still a significant part of the U.S. educational system. The continued strength of the small institution rests on two factors: the special character and appeal which derives from the small size of the institution; and the location of the institution near the home of the student. The fact that the great majority of these small colleges are privately supported and controlled attests to the value placed on them.
>
> Only a small percentage of these small institutions have the staff, facilities, and the instructional equipment deemed desirable for the best instruction in science.
>
> Yet, in spite of this handicap, the small undergraduate college is still the source of perhaps 35 to 40 percent of our young scientists—at all levels of training.
>
> Furthermore, the percentage of all baccalaureates who choose science as a career is apparently greater for the small colleges than for large institutions.

Recommendations

If, as a matter of national policy, this country must now plan for the education and training of increasing numbers of scientists, the facts presented in this memorandum point clearly to the importance of helping the small institutions strengthen their offerings in science. A program designed to help the small institutions should direct its attention, first, to the teaching staff, and second, to facilities and equipment. Were the staff and facilities of small institutions strengthened, even to a small degree, certain important consequences can be anticipated:

> (1) The science majors now attending these small institutions would receive better training.
>
> (2) The small institutions would be able to attract and hold young scientists who now find the prospect of teaching in such institutions unattractive in comparison to the opportunities open to them in the research laboratories of industry, government, or universities.
>
> (3) In the long run, the fraction of students in a small institution who became interested in science would almost certainly increase.

With respect to the kind of support that would be of significant benefit to science teachers in small "weak" colleges the following suggestion is offered:

> The establishment by a Federal agency of a program under which grants equal to 15 percent of annual academic salary can be made to science faculty members in purely undergraduate, 4-year institutions to permit and encourage these faculty members to devote 2 months of their summer vacation period full time to study and work related to their responsibilities as college teachers. For want of a better name we shall refer to this program as the faculty support program.
>
> Grants made under the faculty support program should not be prejudicial to a recipient's making application for support

for other purposes which can also contribute to his qualifications as a teacher; e.g., support for research projects (with or without students), summer institutes, travel to meetings, etc. It is to be understood, of course, that only support supplementary to the salary grant could be requested; that is, the total compensation which a teacher would receive for a summer period would be the 15 percent of his normal academic salary.

Administration of the suggested program could be carried out most simply by leaving it to the administration of a college to request support for its faculty members, a step which would give the administration some responsibility for the operation of the program locally. The paperwork involved in the "request" and the unavoidable "report" should be kept to a minimum, perhaps less than one page per faculty participant.

The foregoing plan should provide both the necessary incentive and flexibility. Its last element is essential because the needs of college teachers are manifold, depending as they do in each individual case on the teacher's background and the history of his department. It is inconceivable that any agency, desirous of helping teachers in small colleges, could design and establish all the programs which would be required to meet the individual needs.

The annual cost of the proposed faculty support program would be well under 1 percent of the annual support given by Federal agencies to scientific research.

STATEMENT SUBMITTED TO THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT OF THE COMMITTEE ON SCIENCE AND ASTRONAUTICS, HOUSE OF REPRESENTATIVES, BY THEODORE R. SIZER, DEAN, HARVARD UNIVERSITY, GRADUATE SCHOOL OF EDUCATION

Over the last 10 years, tremendous strides have been made in the improvement of mathematics and science instruction in secondary schools. National curriculums have been developed. Institutes for experienced teachers have been established. Substantial sums have been made available for laboratory equipment and instructional aids. Salaries of teachers have been increased.

There are two areas in which comparable advances have not been made: (1) graduates of liberal arts colleges have not been attracted to careers in science or mathematics education in anywhere near the numbers needed; (2) in general, the quality of undergraduate programs designed to prepare teachers of mathematics and science leaves much to be desired.

Those universities which offer a fifth-year program of preparation for teaching mathematics and science in the schools (master of arts in teaching programs) have been able to attract a number of graduates of strong liberal arts colleges. These young people typically have completed their undergraduate work with distinction in a demanding program of mathematics and science; they possess intellectual power comparable to those electing other professional endeavors; they enter teaching with a high degree of commitment and enthusiasm. Though few in number, their impact on the schools has been significant. A dramatic increase in the number of students entering teaching with such qualifications could be made. The crucial need is a program of fellowships which would provide financial support for students during their year of preparation for teaching. Harvard's success to date in attracting highly talented students in mathematics and science is in large part due to grants for scholarships from the Sloan Foundation. These funds are no longer available. Other universities are in a similar situation.

With reference to the second problem, undergraduate preparation of mathematics and science teachers, it is clear that radical changes must be made in the conditions which affect the quality of these programs. Standards of admission must be raised; quality of course offerings must be improved; the design of the programs must be reexamined. This is easier said than done. There are over 1,000 institutions of higher education offering undergraduate programs.[1] Even

[1] Though there are over 1,000 institutions engaged in teacher training, we estimate that only 25 percent produce 70 percent of the 20,000 undergraduates licensed to teach mathematics or science in the secondary schools each year. Staffing 250 institutions is a feasible objective. For example, if the universities could graduate 80 doctoral candidates in mathematics education each year (4 in each of 20 universities), in 3 years time we could add 1 highly trained person to each of the 250 institutions which prepare the vast majority of teachers.

if there were agencies—government or private—empowered to mandate change (and there aren't), little change would take place. The real changes must come from within each institution. More specifically, improvements will depend on the quality of mind and the quality of preparation of the member or members of the faculty in such institutions who are directly concerned with mathematics or science education.

The extent to which new staff members possess these qualities in sufficient measure depends ultimately on the universities which prepare instructors in these fields. Such universities must insist on the most demanding admission standards and offer a highly sophisticated program of training both in mathematics (or science) and in pedagogical matters. To recruit the kind of doctoral student who can meet these standards, the universities must have fellowship funds.

In the midfifties, the National Science Foundation launched a bold program of yearlong and summer institutes to increase the competence of experienced high school teachers of mathematics and science. By any gage, this has been an extremely successful program. However, this effort was not aimed at opening up fresh sources of highly talented teachers for the schools. Nor was it directed at the even more difficult task of preparing instructors for the teacher training institutions. The cost of those two endeavors would be relatively modest compared to the outlays needed to upgrade the existing crops of teachers. Indeed, it is not inconceivable that success in the two efforts suggested here could make possible a tapering off of institute programs in the next few years. We strongly urge, therefore, that the National Science Foundation extend its efforts in mathematics and science education to include fellowship programs (1) for graduates of liberal arts colleges who wish to prepare for teaching in the schools, and (2) for doctoral students who are looking toward a career in the teacher-preparing institutions.

STATEMENTS OF CERTAIN MEMBERS OF THE NATIONAL SCIENCE BOARD

AUGUST 16, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development,
House of Representatives, Washington, D.C.

MY DEAR MR. DADDARIO: This letter contains my answers to some of the questions forwarded to Dr. Eric Walker by the Subcommittee on Science, Research, and Development. Since Dr. Walker felt that the subcommittee might be interested in the views of other board members than himself, he has provided us with copies of the questions and has suggested that we reply individually. In order to keep this letter as brief as possible, I am omitting a number of the questions because they involve matters of fact which can best be dealt with in other ways.

1. The National Science Board was characterized by Dr. Waterman in his testimony as "a unique body for dealing with policy matters," and he advocated more use of it within the executive branch by such agencies as the Office of Science and Technology, the Federal Council for Science and Technology and the President's Science Advisory Committee. What is your comment?

I agree with Dr. Waterman that the National Science Board is "a unique body for dealing with policy matters." So far as I know, however, it has never been seriously consulted on matters of scientific policy other than those involved with the operations of the Foundation itself. It might be worthwhile to experiment with using the Board more extensively in setting the national policy toward science. Some of the reasons for feeling that the Board may have special competence in this area are the following:

(*a*) The Board is broadly representative and contains "working scientists," scientific administrators, representatives of the scientifically based professions, and men of affairs.

(*b*) It appears to be rather more detached from specific missions or specialized fields than most other Government boards and committees dealing with scientific matters.

(*c*) It has access to a large and competent staff covering all of basic and much of applied science. Steps are being taken to increase the number and quality of the staff dealing specifically with the gathering of data about science and the formulation of policy.

2. As you know, Reorganization Plan No. 5 would abolish the statutory divisional committees. In his appearance before the Executive and Legislative Reorganization Subcommittee, Dr. Haworth stated that the number of Divisional Committees has proved cumbersome; and he cited as an example that under the National Science Foundation Act three committees were now required to deal with scientific personnel and education matters, whereas one committee was all that was necessary.

(*a*) Rather than abolish all eight divisional committees, why didn't the National Science Foundation just reorganize the three committees concerned with scientific personnel and education?

(*b*) Have the divisional committees really fulfilled their original purpose?

It is my understanding that the request for changing the status of the divisional committees was based largely on the desirability of making it possible for the Director to arrange these high level advisory groups in as useful a way as possible in relation to the organization of the full-time staff of the Foundation. Since the latter must necessarily change with changing needs, it would be unfortunate if the advisory groups related to it could not be changed at the same time.

4. What science policy function does the Board now serve that is not adequately provided for by existing organizational arrangements within the Executive Office of the President?

In practice there is necessarily a good deal of overlap between the National Science Board and the Executive Office of the President. In theory one may say that the President's office is primarily concerned with seeing to it that the scientific establishment is properly prepared for and responsive to specific national needs. Indeed, a good part of the present activities in the executive office arose

from the acute consciousness of the need for expert advice in science as related to National Defense and the exploration of outer space.

On the other hand, the National Science Board was established to represent the needs of science as conceived by the scientific community itself and by the civilian public.

Obviously, there can be no sharp separation between what is "good for science" and what is "good for the Nation." Nor can one be very clear about a distinction between "national needs" and the needs of the general public. Nevertheless, I believe that the shades of emphasis represented by these various terms should be given separate consideration in the formulation of policy and that the present division of responsiiblity between the National Science Board and the Executive Office is good and useful.

5. In your judgment, should NSF be given greater operational authority? Why, or why not?

It is my belief that the NSF has sufficient operational authority if by this is meant the authority to operate programs such as that dealing with research in the Antarctic, atmospheric research, and so on. It is more difficult to say whether the NSF should exercise this authority more fully, either by taking a greater management role in programs now under contract or in developing new operations. There is some question whether the Foundation is adequately staffed and organized for discharging some of the management responsibilities it already has. Fortunately, the problem is recognized within the Foundation and is under active study.

My own views on whether the operational role should be expanded are not completely formed, but I would incline in that direction for the following reasons:

(*a*) Certain types of research must be conducted on a national or international basis and with a considerable degree of coordination. Universities and conventional research institutes have not proven themselves fully competent instruments for investigations of this character. On the other hand, some private foundations have had striking successes. Most notable, perhaps, is the Rockefeller Foundation with its worldwide study of the epidemiology of certain important diseases—hookworm, yellow fever, and malaria—and its more recent work on improving food production in underdeveloped countries. The current success of the antarctic program, and the promise of the National Laboratories established by the NSF suggest that it can do what is necessary if it attacks a problem of this kind wholeheartedly.

(*b*) The presence of an active and successful operating program would increase the prestige and influence of the NSF in the scientific community generally. Furthermore, it would probably be helpful to the present staff to be more closely associated with a group of operating scientists.

(*c*) Experience has shown, especially perhaps at the NIH that the group of investigators in the institute laboratories provides an excellent source of personnel for the executive staff.

6. Do you consider the social sciences as positively within the purview of the Foundation? How does the Board define NSF's role for support of research in the social sciences? Is this role likely to increase or decrease?

I do consider the social sciences as positively within the purview of the Foundation. So far the Board has perhaps given special emphasis to those aspects of social science which can be most clearly related to the more conventional natural sciences, but the definition has been steadily broadened as experience has been gained. I would expect the Foundation's role to increase depending in part on what is done by other Government agencies with responsibilities in this area.

7. The budget of NSF has increased from about $15 to $480 million, and some witnesses have suggested that it become as large as $1 billion in the foreseeable future. With this tremendous growth, is it in the best interest of science to maintain this dual (Board and Director) authority over NSF, or would it perhaps be better to have the Director solely responsible for the management and operation of the Foundation, and have the Board serve in an advisory capacity to the Director (a National Science Advisory Board)?

The present sharing of authority between the Board and the Director is certainly unusual and for various reasons seems unlikely to survive for very long. In its original form, the NSF was, of course, modeled closely on the pattern which had been found successful in the major private foundations. As matters have developed, however, several crucial differences between a private and a Government foundation have come into clear view. The first is that in a private foundation the Board holds title to the assets, and controls both the income and the expenditures. In a public foundation the income results from a series of decisions in the executive and legislative branches.

The second difference is that no single private foundation is large enough to have a controlling effect on the direction of science. The National Science Foundation is not only large enough, it is in fact charged with making decisions and allocations which determine major shifts in direction not only of scientific research but a large part of scientific education as well.

It has proven impossible for the executive and legislative branches of Government to delegate decisions of this magnitude completely to an independent board. The legislation of 1960 making the Director more immediately responsible to the President rather than only to the Board clarified the situation of the Director but increased the ambiguity of the Board's position. Although I have not discussed the matter with enough other people to be sure of my own position, I am beginning to feel—to use the words of your question—that. "it would perhaps be better to have the Director solely responsible for the management and operation of the Foundation, and have the Board serve in an advisory capacity to the Director." Certainly, such a change would result in a clearer more understandable flow of decision making. It might also make it possible for the members of the Board to speak with more freedom about the needs of the NSF to the general public, and at legislative or budgetary hearings.

In my judgment, it would be essential to make sure that the advice of the Board be regularly sought both on questions of policy and on a significant range of day-to-day operations, and it is equally important that the Board continue to feel that its advice is taken seriously both inside and outside the Foundation. Otherwise, it will be difficult to attract people of appropriate calibre to membership on the Board or command their attention once they are there.

Whaever one may feel about the exact legal status of the Board, there can be no doubt of the importance of having such a group of individuals representing both the scientific community and the general public, closely coupled with the policymaking process.

8. What is the Board's fundamental policy with respect to NSF fellowships and grants to universities and colleges? Is your policy aimed primarily at supporting scientific research on the campus, and secondarily at the education of students and the training of science teachers; or is it vice versa?

I doubt if it is very useful to try to draw a distinction between scientific research and scientific education at the university level.

9. What is the Board's view regarding the stationary level of the NSF staff over several years when its own funding and that of Government has sharply grown? Is the staff assistance provided for the Board satisfactory?

I believe that the number and quality of the staff is one of the most important problems facing the Foundation. The present staff, especially at the higher levels, strikes me as very good in quality, but it is seriously overworked. Recent improvements in salaries have helped to retain staff, but the national pool of people who understand both science and administration is very small. Paradoxically, the success of the NSF and the NIH in establishing satisfactory working conditions for scientists in universities and research institutes makes it increasingly difficult to attract the right people into Government office. Everything possible should be done to enable the Foundation to attract more able people. Salaries are important, but perhaps most important of all is the assurance that anyone who joins the staff will have a real opportunity to achieve what he wants for the advancement of science.

10. In what areas should NSF exercise its existing authority further? What new roles do you foresee for the Foundation over the next 10 years and what new authority seems warranted, as for example in areas of applied research and engineering?

I would like to see the Foundation play a more significant role in the international development of science. At least four different roles may be distinguished, in all of which the Foundation already has some experience.

(*a*) The support of international scientific communication—meetings, travel of individual scientists, and support of international programs of investigation, such as the International Geophysical Year. These activities are well understood and supported.

(*b*) Participation in the national program of aid to underdeveloped countries. The Foundation's capability has been demonstrated in a few pilot programs of technical assistance and scientific education, but in spite of marked success it has not been encouraged to develop a program of sufficient size to have real impact. Since technical assistance is not part of the National Science Foundation's regular mission, it might be most appropriately financed by contracts with the AID organization.

(*c*) Support of science in other advanced countries as part of its mission to look after the welfare of science in general. The Foundation has long had a small program of this kind and the principle is well established. Other Government agencies also support investigations in foreign laboratories. In the judgment of many people who have looked into the matter, it appears that if the United States is to have a program of support for science overseas it would be appropriate for the National Science Foundation to play a more significant role. The present situation in which some branches of the Department of Defense are more conspicuous than our civilian agencies in the support of basic science abroad is hard for observers both here and in other countries to understand.

(*d*) Support of science in countries of intermediate status. There is likely to be an increasing number of countries which have passed the first stage of development and no longer need extensive economic assistance, but which have not yet reached fully satisfactory standards in scientific research and higher education. The National Science Foundation is ideally fitted to aid such countries in the establishment of such scientific institutions. Such a program might not have immediate impact but in the long run it would be almost sure to return fine results in the advancement of science and the improvement of international understanding.

The present staff for international work, though excellent in quality, is wholly inadequate in numbers for any but the first of the four activities outlined. A considerable increase would have to be authorized if it were decided to expand in any of the suggested directions.

Others are better qualified than I to discuss the role of the National Science Foundation in relation to applied science, especially engineering. My personal views are conservative. In my opinion, the Foundation has a big job to do in looking after the health of basic science, and it should scrutinize very carefully any suggestion that it take on responsibility for the solution of specific practical problems, such as, for example, the control of air traffic, the desalting of water, or the breeding of more productive strains of wheat. Such problems may more appropriately be attacked with help from the relevant Government agencies—the Departments of Commerce, Interior, and Agriculture, for example. Not only is the specific goal more likely to be kept clearly in mind than it would be if the work were wholly supported by an agency with a more general mission, it is also an excellent thing for any agency with a practical mission to have close contact with an active research program.

Finally, it should be pointed out that National Science Foundation already has a far more active program in the support of engineering activities, both in research and teaching as these are found in universities, than is generally recognized. This program should be continued and expanded as opportunity offers.

13. Are too many Federal agencies today involved in supporting basic science grants and science education? Might not the Foundation assume a more central, or perhaps an exclusive role in this regard?

There are good reasons for encouraging other Federal agencies to support basic scientific investigations and education. Science benefits from multiple support, and conversely it is healthy for most Government agencies to have an active contact with the academic world. The desirability of more coordination and exchange of information among Government agencies is increasingly recognized, and the National Science Foundation has, fortunately, shown a willingness to play a more central role. This tendency should be encouraged.

15. A dropout problem exists for students of science and engineering as well as other subjects. What should the National Science Foundation do to study the reasons for dropouts in secondary schools and colleges? Should it take a mission interest and actively seek to interest investigators in such studies, or should it wait and hope that some scientists will become interested on their own and submit suitable proposals?

The dropout problem as it exists at all levels is an appropriate subject to study with the techniques of social science. The Social Science Division of the National Science Foundation might well search for opportunities to support such investigations.

16. Should the Foundation's national laboratories and, for that matter, the large laboratories of other departments, such as the AEC's Argonne National Laboratory, be treated as permanent national scientific assets to be indefinitely maintained, or should their continued existence depend upon the current vitality and importance of the fields of science in which they excel? Should they have an indefinite mortgage upon future resources for science? If so, what should be their role as efforts and attention of scientists change to new fields?

Support for the national laboratories should, of course, be conditioned by the vitality and importance of the fields in which they excel. It should be recognized, however, that most of the existing laboratories were established in fields about which relatively little is understood and which give promise of producing important information for a long time. They should receive support on the assumption that such support will be needed on an expanding scale for many years.

17. What is your opinion about the proposal that annual funding for National Science Foundation supported basic research be increased by 15 percent annually to accommodate entry of new scientists into independent research and to cover the increased cost of equipment? Do you see graduate schools capable of accommodating a continually growing graduate student body in the sciences? Can the undergraduate colleges be expected to produce more students each year for graduate study in the sciences?

The proposal that the annual funding of the National Science Foundation for the support of basic research increase by 15 percent annually seems to me to have been based on accurate information and sound judgment as applied to the next 5 or 10 years. The question of how long undergraduate colleges and universities can go on producing an increasing number of scientists cannot be precisely answered, but it would appear that we are still considerably short of our maximum potential.

Thank you for giving me this opportunity to comment on this very interesting set of questions. Whether or not the subcommittee finds anything helpful in the answers, I am sure I will be a better Board member for having had to think about them.

Very truly yours,

ROBERT S. MORISON, M.D.,
Member of National Science Board, Director of the Division of Biological Sciences, Cornell University, Ithaca, N.Y.

RICE UNIVERSITY,
Houston, Tex., August 16, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development, House Committee on Science and Astronautics, Washington, D.C.

DEAR MR. DADDARIO: Dr. Eric Walker, Chairman of the National Science Board, has sent to the members of the Board copies of your letter of August 9 enclosing the 19 questions your committee submitted to him after his testimony on July 27. Since it appeared impracticable to convene the Board, or to get a significant consensus, he suggested that some of us might be willing to write you our personal views on some of the questions.

I must especially emphasize that the views expressed below are mine alone, but they are views based on almost 12 years as a member of this Board. The comments are numbered to correspond with your questions to Dr. Walker.

1. The National Science Board is, I believe, unique in that a certain limited amount of authority is conferred on it by statute. It is possible that this authority has not been exercised as vigorously as might have been, but in any case such authority can extend only to the activities of the National Science Foundation itself. The Board can influence other agencies only through persuasion or through the Office of the President.

2. The rather rigid connection between the system of divisional committees and the internal organization of the Foundation staff, although provided in the original act, possibly went somewhat beyond the conscious intent of the authors. The suggested reorganization provides a flexibility such that the divisional committee structure, as well as the staff organization, can be rapidly adjusted to the changing obligations of the Foundation.

3. I doubt if the Foundation should have greater operational authority. Its peculiar function, and the area in which I believe it has been the most valuable, is in the support of small-scale basic research in a wide variety of places and institutions.

I can remember that during the 1930's the Government operated scientific laboratories, at least in the physical sciences, were not highly regarded by the scientific community in the field of basic research. Among the reasons for this was that, in the field of basic research, originality is more important than experience. A research laboratory starts out with an enthusiastic staff and they all grow old together. In a university, the continuing influx of new students can produce a steady stream of new ideas. Most of them are bad, but they can

be evaluated by the senior people. Government and industrial laboratories are now attempting to provide similar conditions, but it is not easy.

During the Second World War the idea of contract research in universities was developed to remedy the deficiencies felt in the Government laboratories. At the end of the war, efforts were made to perpetuate the scheme through the Office of Naval Research, the Research and Development Board, and then through the National Science Foundation. The Foundation has been most effective in this aspect of its work.

It must be emphasized again, that the above comments refer only to basic research. Work in applied research and engineering may very well be done in institutions devoted to such research and engineering only.

7. I believe it is important that the National Science Board retain its present authority. One reason is that it gives the members of the Board a feeling of greater responsibility than would a purely advisory capacity. It permits the President to appoint members of greater stature and it gives the scientific community a feeling that the Board, which to some extent represents them, can have some significant influence upon the policies, at least of the Foundation itself.

9. The staff of the Foundation is quite small when one considers the amount of money they must disburse, in relatively small packages.

On the other hand, the National Science Board has no professional staff at all. The Director has always been most helpful in providing members of his staff to do work for the Board, but the fact that their permanent assignments are on the Director's staff makes it difficult for points of view to be developed apart from those of the Director. Since the two Directors of the Foundation have been men for whom the Board has had the greatest respect, relations have been most amicable, but possible alternative policies may not always have come to the attention of the Board but have been resolved in the staff instead.

In conclusion may I express the gratitude which I feel as a member of the Board for the effective way in which your committee is studying our operations.

Very truly yours,

W. V. HOUSTON,
Member of the National Science Board.

NATIONAL SCIENCE FOUNDATION,
NATIONAL SCIENCE BOARD,
Washington, D.C., August 27, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development, Committee on Science and Astronautics, House of Representatives, Washington, D.C.

DEAR MR. DADDARIO: Dr. Eric A. Walker, Chairman of the National Science Board, has invited the Board to contribute statements concerning the list of questions, addressed to him, in your letter of August 9, 1965. As he noted in his letter to us, several questions are essentially matters of fact to which quite specific factual replies should be supplied. It is my understanding that Dr. Walker will provide these in good course. In the statements below, I have attempted to summarize my own reaction to several of the cogent questions which you have put to Dr. Walker.

Question 1. The President's Science Advisory Committee is appointed with the substantive nature of various aspects of science and their specific relationship to the diverse but highly specific missions of many Federal agencies in view. Because of the general flow of information to PSAC and its clear relationship to the special assistant to the President for science and technology, this committee attempts to remain cognizant of the total commitment of the Federal Establishment in science and technology, the manner in which the funds for these purposes are distributed through the specific agency budgets, the impact of such techniques of funding on universities, the civilian economy, and the Federal Establishment. These are broad charges indeed and the part-time PSAC finds it a full-time task to gather the necessary comprehensive view which would permit a firm grasp of the many relationships involved. As you know, a substantial portion of PSAC is spending the summer at Woods Hole grappling with just these problems.

In contrast, the National Science Board represents a wider cross-section of background an dexperience than does PSAC. Accordingly, it is in better position to recognize the impact on, and contributions to, Federal policies for science on the part of industrial organizations, small liberal arts colleges, the great uni-

versities, and the scientific community generally. It is precisely because of this diverse composition that the Board can serve the National Science Foundation well in a policymaking role. On the other hand, the Board long ago adjured the larger role for national science policymaking originally envisioned for it in the act. In retrospect, this early position of the Board was a wise decision and the original reasoning retains its validity. No board which exists in a unique relationship to a single operating agency should be asked also to serve in a broader policymaking capacity. Such a broader policymaking organization is indeed required and it is this role which is presently assigned to PSAC which can serve in this capacity by virtue of the very fact that it bears no specific responsibility for any specific agency of Government.

PSAC–OST and the National Science Board are not in conflict nor do they overlap significantly in function. Rather can they maintain a useful dialog. As the Board and Director with their responsibilities and concern for basic science establish the role of the Foundation in support of specific scientific disciplines, it is to PSAC–OST that this information is communicated so that the total Federal program may be shaped and balanced.

Accordingly, I endorse the statement made by Dr. Waterman with respect to the Board.

Question 2. Those of us who are "alumni" of the divisionel committees of the Foundation are quite divided in our views with respect to the usefulness of the divisional committees. The act placed upon the Board responsibility for policymaking as well as the direct awarding of grants, etc. The program panels are composed of experts in specific scientific disciplines and are in best position to render judgment on the scientific merits of proposals which come to the Foundation. But no really specific role was created for divisional committees. Some of the latter have felt that they contributed significantly to the vigor and integrity of the Foundation's programing; others have felt that their committees were essentially useless. In retrospect one may wonder as to whether these committees have been adequately exploited on behalf of the Foundation.

In the most significant sense, the divisional committees should have been the means of assuring the coupling between the scientific community and the Foundation, a problem to which Dr. Walker referred in his testimony. To some degree this has surely been the case. But it now seems to me that these committees were not asked to work sufficiently hard. For example, it might well have been these committees which undertook the task of generating the studies of science, by particular fields and discipline, which have more recently been undertaken by specific subcommittees of the Committee on Science and Public Policy of the National Academy of Sciences. Perhaps it should have been these committees which should have signaled in sufficient time the needs of astronomy or the fact that, for lack of a natural home among the mission-oriented agencies of Government, the science of chemistry has been supported in a fashion which is not commensurate with the role of this science in the national economy or its significance in health, agriculture, or defense.

I do not think the question of the precise number or composition of the divisional committees is a significant issue in the life of the Foundation. However, the role of these divisional committees is a significant issue and that role should be more clearly defined at an early date.

Question 4. It is the function of the Board to generate policy with respect to the operations of the National Science Foundation—not for the totality of science or technology in the Federal Establishment. To be sure, in order to do so effectively, the Board must be quite cognizant of the programs of other agencies. But the Board is in far better position than is PSAC, for example, to estimate the need for and magnitude of the program of course content improvement or the magnitude of Foundation support of molecular biology. At the same time, the Board serves in a general sense as overseer of the national laboratories and programs which have become the responsibility of the Foundation. In contrast, while PSAC must concern itself with these problems in the most general way, its involvement with various aspects of the Defense Establishment, civilian technology, high energy physics, earthquake prediction, national manpower needs, etc., is of such intensive nature that the details of policy for the National Science Foundation—even though it be a one-half-billion-dollar-a-year enterprise—are simply beyond the capabilities of the PSAC. And there is no other external committee anywhere in Government which could accept the functions of the National Science Board.

Clearly there is required a hierarchy of decision and policymaking. At each level, scientists and representatives of the public, external to the Federal Establishment, can usefully contribute. These various layers are not necessarily

subservient to those above; rather, as one proceeds up the ladder, one is concerned with problems of ever-broadening nature. Although this system may not be perfect, it is working remarkably effectively.

Question 5. In my years of service on the National Science Board I have become ambivalent with respect to the desirability of a broadened operational authority for the National Science Foundation. Conceived entirely as a granting agency, by virtue of its very responsibilities for insuring the vitality and integrity of the entire national effort in basic research, the Foundation has accepted responsibility for a series of what may be termed "wholly owned subsidiaries." These include the Kitt Peak National Observatory, the National Radio Astronomy Observatory, the National Center for Atmospheric Research, and the Mohole project as well as programs in the Arctic and Antarctic. In each instance, the Foundation has entered into a contractual relationship with another organization, usually a synthetic corporation which is a consortium of universities. Nevertheless, the rest of Government, including the Congress, looks to the Foundation for the policies which shall obtain and the conduct of these national facilities and programs. And it is the Foundation and its Board which, together with congressional approbation, establishes the level of funding of each such operation. The Foundation has responsibility, yet the current arrangements deprive it of authority for the actual management of these facilities. One might readily suggest that, were each laboratory and facility directed by a management group which in turn is directly responsible to the Director of the Foundation, the Foundation and hence the Congress and executive branches could be more certainly assured that the original purposes which underlay the creation of these facilities would continue to be served. The necessary scientific advice with respect to program details could continue to derive from an external scientific advisory body for each such facility. But in practice the current, seemingly contrived, arrangements have worked quite adequately. And the scientists and universities have a sense of "belonging" to Kitt Peak, NCAR, or Greenbank which they would certainly otherwise lack. The fiscal control exerted by the Foundation appears sufficient as a means of assuring that the Government's purpose in creating these laboratories is safeguarded.

Accordingly, although there may one day appear some opportunity which could not be grasped for lack of direct operating authority, there seems to be no compelling requirement for such authority today.

Question 6. I share the view of the Board that the social sciences quite definitely fall within the purview of this Foundation. However, the Foundation has taken a restriced view of what constitutes social science. This view has served to protect the Foundation from involvements in controversial issues since it relates the Foundation to quantifiable aspects of the social sciences and divorces the Foundation from matters which might be called opinion.

But it is increasingly clear that man has learned to develop science and technology with greater skill than he has learned to manage human interrelationships either at the individual or societal level. Since much of the social ferment of our time is a consequence of the scientific and technological revolution, it certainly behooves the Foundation to be increasingly aware of the social implications of science as a very minimum of its interest in research and education in the social sciences. In the long run, however, this is clearly insufficient. Hence, I cannot help but feel that the role of the Foundation in the development and support of social sciences in our country will expand significantly in the future.

Question 7. My views with respect to the relationship between the Board and the Foundation were offered in an earlier letter addressed to Dr. Haworth in commentary upon the testimony of Dr. Walker. Increasingly, the role of the Board must be restricted to the formulation of policy and advice in only the larger, overall matters which come before the Foundation. I share the view that the budget of the Foundation should continue to grow rapidly for the next 10 years and would be happy to document this on another occasion. But at that level of activity, a part-time Board cannot expect to accept responsibility for the award of grants. It must be kept informed with respect to grant awards to that it can remain in as intimate relation to the affairs of the Foundation as possible. Policy in the abstract is without meaning. The Board must decreasingly serve as a monitor over the actual granting process yet it must remain highly informed with respect to the grants program so as to be aware of problems, of changes in the role of the Foundation in our society, of changes in the nature of requests brought to the Foundation, of changes in the practices of universities, of the needs of individual scientists, of scientific disciplines, of research and educational institutions, etc.

In point of fact, however, I hold no brief for the legal arrangements whereby this is accomplished. Whether the Board is legally stripped of its authority and placed in a strictly advisory policymaking role, or whether it surrenders its authority by delegation to the Director as has been increasingly the practice in the last several years, is to me a matter of little concern. As long as the appointments to the Board continue to be prestigious scientists, university administrators, and public figures, I am confident that the Director neither would nor could ignore firm recommendations to him from such a body. On the whole I prefer the status, de jure, of the Board to reflect its de facto role. And, increasingly, that role is advisory with respect to policy.

My concern in this regard derives only from the alarm which such a statutory change might arouse in the academic and scientific communities. But as long as the membership of the Board is appointed by the President and confirmed by the Senate, a practice which should be continued, this impact should be relatively slight.

In considering the role of the National Science Board, no analogy to the board of a corporation, university or private foundation is really valid. The board of a private foundation is answerable only to itself, within the broad constraints imposed by the law. But the National Science Foundation is responsible to the President and to the Congress. Its policies must be compatible with the total policy for science created by Congress and by the White House. It does not generate its own funds; these are sought from the Congress which is, in a real sense, the Board of Trustees of the Foundation. Accordingly, the legal position of the National Science Board is anomalous at best.

Question 9. I have no complaint with respect to the nature or magnitude of the staff assistants provided for the Board. But I should not that any knowlegeable individual who spends a significant amount of time at the Foundation soon becomes aware of the fact that, at the professional levels, the Foundation staff is diligent, dedicated, and overworked. The administrative costs in the operation of this Foundation represent a small fraction of those which could be expended by a private foundation similarly engaged.

Question 10. There is little doubt in my mind that there will be brought to the Foundation at frequent intervals suggestions for the development of new national facilities and programs in various areas of science. It is difficult to be certain which of these will offer sufficient promise as to warrant support viewed from this prospect.

I am insufficiently informed with respect to the nature of the engineering sciences to be certain of the lines which separate research in enginering science from the practice of engineering itself. I am completely comfortable with vigorous support of programs in engineering science by the Foundation and such authority already exists. In practice, support is given only to those projects addressed to problems of rather broad significance or application. Nor have I objection in principle to the direct support of engineering research per se. But such research must be directed to specific and practical goals. And it is difficult to imagine such engineering projects which do not appear to fall within the purview of some other agency of government and have direct relevance to its mission. Should the Department of Commerce or the NSF be concerned with improvemnts in techniques of surface transportation or of underground power transmission? Should Commerce or NSF concern itself with improved construction techniques for schools, residences, and offices? This line of reasoning seems to extend to all specific projects which have come to my attention and whereas I agree that in many instances the appropriate Government agency appear to have been laggard, my reaction is to suggest that such agencies be prodded to more vigorous pursuit of their missions rather than to have the National Science Foundation undertake their tasks. Nevertheless, I have no objection in principle and, indeed, rather favor a program of carefully selected engineering projects supported by the Foundation.

Question 13. The case against a monolithic Federal Department of Science has been made many times, and I can only associate myself with this position. Science and technology pervade all aspects of human affairs and accordingly are relevant to virtually all agencies of Government. To assure that each of these agencies pursues its own mission with maximum effectiveness, it is imperative that its own scientists remain in constant and mutually fruitful relationship with basic scientists and particularly those in the universities. By the same token, this network of relationships insures that there will be competent and knowledgeable scientists in the universities aware of the specific problems which confront their counterparts in the Federal agencies. Such relationships do not warp

the structure of freely undertaken university science. Rather does it awaken the university scientist to possibilities and opportunities of which he might otherwise have been totally unaware. At the same time, as he seeks funds in support of his own university-based endeavors, he is assured of more than one jury which will provide a hearing for his ideas. The current multiagency support of science, which is more a historical accident than the consequence of purposeful policy, has demonstrated its enormous strengths and should not be disturbed in principle unless there is a profound conviction that some other system will work as well.

On the other hand, it is also true that the National Science Foundation, quite uniquely, is the agency of Government created expressly to assure a balanced, vigorous national program in science in all of its aspects. Clearly this is not possible unless the Foundation has operating funds of sufficient magnitude to permit it to fulfill this heavy and broad responsibility. It is difficult to establish some magic formula by which one can calculate the exact fraction of the total Federal support of science which should be provided through the Foundation. Surely, 12 percent of the total support of university-based fundamental research is insufficient. Quite as surely, 75 percent of such support would be more than is required for the general purposes of the Foundation and would not permit the mission-oriented agencies the advantages which presently accrue to them in consequence of the current support pattern. Thus it would appear that perhaps 25 to 40 percent of the total Federal support of science should be made available through appropriations to the National Science Foundation. And this can be accomplished by a growth rate in the total Federal support of science which, for a few years, is skewed in favor of the appropriation for NSF.

Question 16. The national laboratories sponsored by the Foundation are great national assets. At least two of these, those at Kitt Peak and at Greenbank, were created to provide large and expensive, highly specialized scientific instrumentation which are then made available to the entire national community of scientists. These laboratories should remain in existence and be supported by the Foundation as long as their facilities make possible significant contributions to science. It is entirely conceivable that, one day, their expensive apparatus will be outmoded and that newer instrumentation providing yet greater capabilities will have been designed. Since, in all likelihood, such newer instrumentation will be costly and complex, it will again appear to be wise to place them in national laboratories. But should this projection fail to materialize, should current equipment not be succeeded by another generation of optical and radio telescopes and should the current instrumentation fall into disuse, the Foundation should not hesitate to close these laboratories.

The second portion of this question raises a problem which has deeply troubled many of us on the Board. The programs of these laboratories, as well as their equipage require considerable leadtime. Plans are made years in advance, contingent upon subsequent funding. At a time when the general grants program is not growing at the rate which had been hoped for by the scientific community, the Foundation staff and by the Board, the national laboratories represent a standing commitment against Foundation funds. These laboratories acquire the status of a preferred customer although this was clearly not the intention of the Board when preferred customer although this was clearly not the intention of the Board when the laboratories were created. To fail to fund the national laboratories at a level commensurate with their potential seems unwise, but no more so than is the failure to fund other meritorious projects which arise spontaneously within the scientific community and are brought to the Foundation for funding in the same year. The Foundation has no alternative but to fund the national laboratories at a level adequate to keep them in operation under such circumstances but even this concept has been extremely troublesome. This painful choice was apparent in the distribution of funds in the fiscal year 1964 and fiscal year 1965 budgets. Since the Board continues in its belief that optical astronomy, radio astronomy, and atmospheric science are among the most exciting of current scientific ventures, this decision was not quite as painful as otherwise it might have been.

Question 17. This series of questions can be rephrased as "How large should the national scientific enterprise be?" I know of no simple a priori grounds or set of first principles which permits a quantitative answer to this question. As a nation, we are aware that science and its offspring, technology, have remodeled our land, that they assure our defense, improve our health,

provide a sense of adventure, and each day make our lives more comfortable if not happier.

The magnitude of the scientific enterprise which has made this possible has, to be sure, reflected our national purpose. But more simply, the level of funding has been determined by the "state of the art" in each scientific discipline and the available supply of practitioners of those disciplines.

In the last analysis, therefore, our expenditures on science reflect the number of scientists in being and the number in training.

Despite the great publicity given to science and its accomplishments, the proportion of high school and college graduates who choose careers in science has not been rising significantly. But since the total number of students continues to rise as a consequence of our increase in population and the fortunate circumstances which make it possible for increased numbers of high school graduates to go to college and of college graduates to undertake graduate education, the total number of potential scientists continues to rise.

The scientific frontiers are by no means closed. Each scientific venture raises more problems than it answers and this trend will continue for many years to come. Those who share the belief that science and its derivative technology will continue to expand our wealth, increase our health, and assure our safety, see no objection to an ever-increasing scientific force until such time as the scientific enterprise grows to such proportion that it becomes too expensive for our Nation to maintain. I cannot state with any conviction what the level of effort—relative to the gross national product—may be. But I am convinced that it is an effort vastly larger than that which we currently manage. Accordingly, I believe that projections for the support of science over the next 10 years or so should be based on the numbers of graduate students which may be anticipated, the size of the scientific force which will be so created, and the costs of their investigations. The estimate that this program can be maintained if the funds provided increase at a rate of approximately 15 percent per year has been validated by a series of approaches. The 15-percent figure is not a magic number but rests on rather sound grounds including the number of academic scientists currently active, the rate of attrition from this force, the number of new graduate students to be expected from among those currently in college, the increased sophistication of scientific research, and a conservative estimate of inflationary trends.

Meanwhile, our colleges and graduate schools simply must expand their activity so as to assure future college graduates of the kind of education to which they aspire. This will require investment in physical plant, and continuing expansion of the university faculties by retention of substantial numbers of their own products. But this pattern does not differ dramatically from which we have witnessed in the last 10 years. Only the scale of the enterprise is to be expanded and that in proportion to our growing national population and national wealth.

Finally, a few concluding remarks.

1. There is a subtle value to the role of the Foundation within the total Federal support of science which is difficult to document. But it is nevertheless true that it is the Foundation which gives "tone" and dignity to this enterprise. Science, supported through the Foundation, is clearly one of the most highly civilized of human activities and the understanding of man and the universe in which he finds himself is among the noblest of human aspirations. The manner and attitudes of the Foundation in the support of science increasingly serve as a model for other agencies, both public and private.

2. Quite frequently, the programs of the Foundation have been justified as "science for science's sake." And whereas this attitude may be relatively widespread among scientists working at the bench, those of us who serve on the Board and on the Foundation staff are ever mindful of the social purposes of science. In viewing applications for research support and in constructing the annual budget, there is full awareness of those aspects of chemistry which will contribute ultimately to the growth of our national chemistry industry, of those aspects of biology which will contribute to improvement in human health, in agriculture, and in the quality of life, of those aspects of physics which will one day make possible improved communications, transportation, and utilization of power. Science, supported by the Foundation, is not simply an exercise in the construction of a gigantic intellectual edifice, it is preliminary to continual improvement of the human condition.

Sincerely yours,

PHILIP HANDLER,
Vice Chairman, National Science Board.

APPENDIX 4

CURRICULUM STUDY GROUPS*

A wide variety of educational projects including curriculum studies are supported by the National Science Foundation in its course content improvement programs. According to an NSF status report on the subject prepared in March 1965, almost no two of these are alike. They include, for example, NSF-sponsored conferences on course content, small-scale student experimental projects in the use of materials, NSF support of college-level commissions on various scientific subjects, and instructional equipment development.

In addition, and most prominent of all, are the so-called materials development projects—like the biological sciences curriculum study underway at the University of Colorado—which are designed to develop, try out and eventually make available a battery of instructional materials for classroom use. These include textbooks, student manuals and teachers' guides similar to those displayed to the Committee. Subjects covered at various institutions in 18 States include, besides biology, the following: physics, mathematics, social sciences, engineering, chemistry, earth sciences, elementary, and junior high school science.

The major projects of this nature supported by NSF are listed below in two groups, including those handled by (A) the Division of Pre-College Education in Science, and (B) the Division of Undergraduate Education in Science:

COURSE CONTENT IMPROVEMENT PROGRAM

TABLE A.—*Division of pre-college education in science*

Institution and project title	Director	Address of director
K-12 MATHEMATICS AND HIGH SCHOOL SCIENCE		
Stanford University, Math in Elementary Schools.	Patrick Suppes	Institute for Mathematical Studies, Stanford University, Stanford, Calif.
University of California, Chemical Education Materials Study.	George C. Pimentel	Department of Chemistry, University of California, Berkeley, Calif.
Commission on Engineering Education, Engineering Concepts Curriculum Project.	E. E. David, Jr	Bell Telephone Laboratories, Murray Hill, N.J.
Educational Services Inc., Cambridge Conference on School Mathematics.	William T. Martin	Department of Mathematics, Massachusetts Institute of Technology, Cambridge, Mass.
University of Illinois, University of Illinois Committee on School Mathematics.	Max Beberman	University of Illinois Committee on School Mathematics, University of Illinois, Urbana, Ill.
Webster College, Madison Project	Robert B. Davis	Department of Mathematics, Syracuse University, Syracuse, N.Y.
Wesleyan University, Coordinate Geometry.	Robert Rosenbaum	Dean of the Sciences, Wesleyan University, Middletown, Conn.
Educational Services Inc., Elementary Films.	David A. Page	Educational Services Inc., 164 Main St., Watertown, Mass.

*Information provided by the National Science Foundation.

Institution and project title	Director	Address of director
Stanford University, School Mathematics Study Group.	E. G. Begle	School Mathematics Study Group, Stanford University, Stanford, Calif.
Earlham College, Chemical Bond Approach.	Laurence E. Strong	Department of Chemistry, Earlham College, Richmond, Ind.
Educational Services Inc., Physical Sciences Study Committee.	Jerrold Zacharias	Educational Services Inc., 164 Main St., Watertown, Mass.
ELEMENTARY AND JUNIOR HIGH SCHOOL SCIENCE		
American Association for the Advancement of Science, Commission on Science Education.	John R. Mayor	American Association for the Advancement of Science, 1515 Massachusetts Ave., NW., Washington, D.C.
Educational Services Inc., Elementary Science Study.	Charles Walcott	Elementary Science Study, Educational Services Inc., 108 Water St., Watertown, Mass.
University of Minnesota, Math and Science Teaching Project.	James Werntz	Institute of Technology, University of Minnesota, Minneapolis, Minn.
Princeton University, Secondary School Science Project.	Frederick Ferris	Department of Geology, Princeton University, Princeton, N.J.
University of California, Science Curriculum Improvement Project.	Robert Karplus	Department of Physics, University of California, Berkeley, Calif.
University of Illinois, School Science Curruculum Project.	Richard Salinger	School Science Curriculum Project, 805 West Pennsylvania, Urbana, Ill.
Educational Services Inc., Physical Science for Junior High School.	Uri Haber-Schaim	Educational Services Inc., 164 Main Street, Watertown, Mass.
University of Illinois, Elementary School Science Project.	J. Myron Atkin, Stanley P. Wyatt.	Elementary School Science Project, University of Illinois, Urbana, Ill.
SOCIAL, BIOLOGICAL, AND EARTH SCIENCES		
Educational Services Inc., Social Science Project.	Elting Morison	Department of History, Massachusetts Institute of Technology, Cambridge, Mass.
American Geological Institute, Earth Science Curriculum Project.	Robert Heller	Earth Science Curriculum Project, Post Office Box 1559, Boulder, Colo.
American Meteorological Society, Meteorology Films.	Kenneth Spengler	Executive Secretary, American meteorological Society, 45 Beacon Street, Boston, Mass.
Association of American Geographers, High School Geography Project.	Nicholas Helburn	Department of Earth Sciences, Montana State College, Bozeman, Mont.
American Sociological Association, Sociological Resources in Secondary Schools.	Neal Gross	Graduate School of Education, Harvard University, Cambridge, Mass.
University of Colorado, Biological Sciences Curriculum Study.	Arnold Grobman	Biological Sciences Curriculum Study, University of Colorado, Boulder, Colo.

TABLE B.—*Division of undergraduate education in science*

Institution and project title	Director	Address of director
SCIENCE EDUCATION COMMISSIONS		
American Association for the Advancement of Science, Commission on Science Education.	Paul B. Sears	Department of Botany, Yale University, New Haven, Conn.
National Academy of Sciences, Commission on Educational Policy in Agriculture.	A. E. Darlow	Dean of Agriculture, Oklahoma State University, Stillwater, Okla.
George Washington University, Commission on Undergraduate Education in the Biological Sciences.	Thomas S. Hall	Department of Zoology, Washington University, St. Louis, Mo.
University of Pennsylvania, Advisory Council on College Chemistry.	Charles C. Price	Department of Chemistry, University of Pennsylvania, Philadelphia, Pa.
Commission on Engineering, Education.	William Everitt	Dean, College of Engineering, University of Illinois, Urbana, Ill.
Association of American Geographers, Commission on College Geography.	Arthur H. Robinson	Department of Geography, University of Wisconsin, Madison, Wis.
American Geological Institute, Council on Education in the Geological Sciences.	Oliver T. Hayward	Department of Geology, Baylor University, Waco, Tex.
Mathematical Association of America, Committee on the Undergraduate Program in Mathematics	W. L. Duren, Jr.	221A Thornton Hall, University of Virginia, Charlottesville, Va.
University of Michigan, Commission on College Physics.	Matthew Sands	Stanford Linear Accelerator Center, Stanford, Calif.
MATHEMATICS		
Mathematical Association of America, Films and Other Teaching Materials for College Mathematics.	Carl B. Allendoerfer	Department of Mathematics, University of Washington, Seattle, Wash.
PHYSICS		
University of Washington, Materials for Undergraduate Curriculums in Physics.	Ernest Henley	Department of Physics, University of Washington, Seattle, Wash.
ENGINEERING		
Educational Services, Inc., Motion Pictures to Improve Instruction in Fluid Dynamics.	Arthur Bryson	Educational Services, Inc., 108 Water St., Watertown, Mass.

The NSF status report of March 1965 includes a description of publication procedure, as follows:

It is desirable that the end products—textbooks, guides, films, etc.—be made available for purchase by schools for regular usage. The Foundation authorizes the grantee to enter into a contract with a publishing firm for the publication and sale of the materials. In the case of films, contracts for film rental as well as sales are permitted. The grantee is required to solicit proposals widely from the publishing industry. Each proposal is studied by the grantee and evaluated against criteria approved by the Foundation. The criteria include consideration of design, binding, and printing of the materials; proposed sales program, selling price, return of royalties; and other financial considerations. The grantee subsequently chooses one. The Foundation approves when it is satisfied that the competition has been fair and the choice of publisher made on satisfactory grounds. The grantee and the publisher then negotiate a contract. The Foundation requires that, as a minimum, the contract provides a fair return in royalties to the grantee, that the publisher may not effect a revision without prior approval, that foreign rights are controlled and that there is an adequate Government-use clause. No fixed royalty rate is required. Control of the copyright remains with the grantee.

The status report also includes a tabulation of published instructional materials, mainly textbooks, developed with NSF support. These include the 12 biology curriculum books, pamphlets, and teachers' guides displayed to the committee by Dr. Arnold B. Grobman, director of the biological sciences curriculum study located at Boulder, Colo. Other instructional materials have been developed with NSF

support on the subjects of chemistry, physics, mathematics, and elementary science. The list follows:

PUBLISHED INSTRUCTIONAL MATERIALS DEVELOPED WITH FINANCIAL SUPPORT OF THE NATIONAL SCIENCE FOUNDATION

This list is limited largely to definitive versions of printed materials (textbooks, laboratory guides, teachers' guides, supplementay readings) now available to any who wish to obtain them. Preliminary experimental versions, special reports, films, other audiovisual aids, and equipment are not listed here.

I. Biological sciences curriculum study (BSCS)

1. Blue version: "Biological Sciences: Molecules to Man," Houghton Mifflin Co., 2 Park Street, Boston, Mass., 02107. (Molecular and evolutionary approach.) Includes text, students' manual, teachers' guide.
2. Green version: "High School Biology, BSCS Green Version," Rand McNally Co., Post Office Box 7600, Chicago, Ill., 60680. (Ecological and evolutionary approach.) Includes text, students' manual, teachers' guide.
3. Yellow version: Biological Science: An Inquiry Into Life," Harcourt Brace & World Co., 757 Third Avenue, New York, N.Y., 10017. (General and cellular approach.) Includes student laboratory guide, teachers' manual for student laboratory guide, teachers' guide.
4. "BSCS Version Quarterly Tests" (version publishers).
5. "BSCS Comprehensive Final Exam," Psychological Corp., 304 East 45th Street, New York, N.Y., 10017.
6. Laboratory Blocks, D. C. Heath & Co., 285 Columbus Ave., Boston, Mass., 02116:
   "Plant Growth and Development."
   "Animal Growth and Development."
   "Microbes: Their Growth, Nutrition and Interaction."
   "Interdependence of Structure and Function."
   "Genetic Continuity."
   "Life in the Soil."
   "Metabolism."
   "Physiological Adapability in Animals."
   "Field Ecology."
7. "Innovations in Equipment and Techniques for the Biology Teaching Laboratory," D. C. Heath & Co.
8. "Biology Teachers' Handbook," John Wiley & Sons, Inc., 605 Third Avenue, New York, N.Y., 10016.
9. "Research Problems in Biology: Investigations for Students," series 1 and series 2, Doubleday & Co., Inc., 501 Franklin Avenue, Garden City, N.Y., 11530.
10. BSCS pamphlet series, D. C. Heath & Co. (16 titles; more coming).
11. BSCS bulletin series, BSCS, University of Colorado, Boulder, Colo., 80304:
    "Biological Education in American Secondary Schools, 1890–1960" (Hurd).
    "Teaching High School Biology: A Guide to Working with Potential Biologists" (Brandwein, Metzner, Morholt, Roe, Rosen).
    "BSCS Biology: Implementation in the Schools" (Grobman, Hurd, Klinge, Lawler, Palmer).
12. BSCS special publication series, BSCS:
    "BSCS Biology Guidelines for Preparation of In-Service Teachers," No. 1 (Klinckmann).
    "Patterns for the Preparation of BSCS Biology Teachers," No. 2 (Cox).
    "BSCS Materials for Preparation of In-Service Teachers of Biology," No. 3 (Andrews).

II. Chemical bond approach project (CBA)

"Chemical Systems," McGraw-Hill Book Co., Inc., 330 West 42d Street, New York, N.Y., 10036; also teacher's guide.

"Investigating Chemical Systems" (McGraw-Hill); also teacher's guide.

"Supplementary Readings for Chemical Bond Approach," reprinted from "Scientific American," W. H. Freeman & Co., 660 Market Street, San Francisco, Calif., 94104.

"Supplementary Readings for Chemical Bond Approach," reprinted from "Journal of Chemical Education," Chemical Education Publishing Co., 20th and Northampton Streets, Easton, Pa., 18042.

III. Chemical education material (Chems)

1. Available from W. H. Freeman & Co., CHEM Study, 660 Market Street. San Francisco, Calif., 94104.
   "Chemistry: An Experimental Science."
   Laboratory Manual: "Chemistry: An Experimental Science."
   "Teacher's Guide for Chemistry: An Experimental Science," 2 volumes.
   "CHEM Study Achievement Examinations."
   Programed Instruction Pamphlets: "Use of Exponential Notation, Use of the Slide Rule."

IV. Physical science study committee (PSSC)

"Physics," D. C. Heath & Co., 285 Columbus Avenue, Boston, Mass., 02116.

"P.S.S.C. Physics. Teacher's Resource Book," parts 1, 2, 3, 4, D. C. Heath & Co., 285 Columbus Avenue, Boston, Mass., 02116.

"Physics Laboratory Guide," D. C. Heath & Co.

"Tests of the Physical Science Study Committee," Educational Testing Service, Princeton, N.J., 08540.

"Teacher's Guide to the PSSC Films," Modern Learning Aids, 3 East 54th Street, New York, N.Y., 10022.

Science study series, paperback books (38 titles), Doubleday & Co., Inc., 501 Franklin Avenue, Garden City, N.Y., 11530.

V. School mathematics study group (SMSG)

1. Published by Yale University Press, School Mathematics Study Group, 92A Yale Station, New Haven, Conn., 06520. Each item includes a student text and a teacher's commentary:
   "Mathematics for the Elementary School," spearate for grades 4, 5, 6.
   "Mathematics for Junior High School," volume 1 and volume 2.
   "Introduction to Secondary School Mathematics," volume 1 and volume 2.
   "Introduction to Algebra."
   "First Course in Algebra."
   "Geometry."
   "Geometry with Coordinates."
   "Intermediate Mathematics."
   "Elementary Functions."
   "Introduction to Matrix Algebra."
2. Available from A. C. Vroman, Inc., 367 South Pasadena Avenue, Pasadena, Calif., 91105.
   a. Studies in mathematics (for teachers):
      "Euclidean Geometry Based on Ruler and Protractor Axioms."
      "Structure of Elementary Algebra."
      "Geometry."
      "Concepts of Informal Geometry."
      "Number Systems."
      "Intuitive Geometry."
      "Concepts of Algebra."
   b. "Mathematics for the Elementary School," separate for grades K, 1, 2, 3.
   c. Mathematics through science:
      "Measurement and Graphing."
      "Graphing, Equations and Linear Functions."
      "An Experimental Approach to Functions."
   d. "Programed First Course in Algebra" (3 versions).
   e. "Analytic Geometry."
   f. "Very Short Course in Mathematics for Parents."
   g. Conference reports:
      "Conference on Elementary School Mathematics."
      "Orientation Conference for SMSG Experimental Centers."
      "Orientation Conference for SMSG Elementary School Experimental Centers."
      "Orientation Conference for Geometry With Coordinates."
      "Conference on Future Responsibilities for School Mathematics."
   h. Junior high school mathematics units:
      "Number Systems."
      "Geometry" (separate text and commentary).
      "Applications" (separate text and commentary).
   i. "Study Guides in Mathematics" (for teachers—algebra, geometry, number theory, probability, and statistics).

j. "Study Guides in Calculus."

k. Supplementary units:

"Junior High School Supplementary Unit" (separate text and commentary).

"Essays on Number Theory," I and II.

"Development of the Real Number System."

l. Supplementary and enrichment series.

"Functions."

"Circular Functions."

"Functions, Circular Functions" (teacher's commentary).

"The Complex Number System" (separate text and commentary).

"The System of Vectors" (separate text and commentary).

"Non-Metric Geometry" (separate text and commentary).

"Plane Coordinate Geometry" (separate text and commentary).

"Inequalities" (separate text and commentary).

m. Spanish translations:

"Matemáticas Para el Primer Ciclo Secundario," volume 1.

"Matemáticas Para el Primer Ciclo Secundario," volume 2.

"Matemática Para la Escuela Scundaria, Primer Curso de Algebra."

"Matemática Para la Escuela Secundaria, Geometria."

3. Available from New Mathematical Library, L. W. Singer Co., Inc., 249–259 West Erie Boulevard, Syracuse, N.Y., 13202:

"Numbers—Rational and Irrational" (Niven).

"What is Calculus About?" (Sawyer).

"An Introduction to Inequalities" (Beckenbach, Bellman).

"Geometric Inequalities" (Kazarinoff).

"The Lore of Large Numbers" (Davis).

"The Contest Problem Book."

"Uses of Infinity" (Zippin).

"Geometric Transformations" (Yaglom, Shields).

"Continued Fractions" (Olds).

"Graphs and Their Uses" (Ore).

'Hungarian Problem Book," volume 1 and volume 2 (Rapaport).

'Episodes From the Early History of Mathematics" (Aaboe).

VI. Some other publications of interest

1. Survey of recent East European literature on school and college mathematics: List of books, pamphlets, etc. (over 50 titles) available in English translation may be requested of Dr. Alfred L. Putnam (project director), department of mathematics, University of Chicago, Chicago, Ill., 60637.

2. Topics in mathematics, D. C. Heath & Co., 285 Columbus Avenue, Boston, Mass., 02116:

"Algorithms and Automatic Computing Machines" (Trakhtenbrot).

"Areas and Logarithms" (Markushevich).

"Computation of Areas of Oriented Figures" (Lopshits).

"Configuration Theorems" (Argunov, Skornyakov).

"Equivalent and Equidecomposable Figures" (Boltyanskii).

"The Fibonacci Numbers" (Vorobyov).

"How To Construct Graphs" (Shilov) with "Simplest Maxima and Minima Problems" (Natanson).

"Hyperbolic Functions" (Shervatov).

"Induction in Geometry" (Golovina, Yaglom).

"Introduction to the Theory of Games" (Venttsel').

"The Method of Mathematical Induction" (Sominskii).

"Mistakes in Geometric Proofs" (Dubnov).

"Proof in Geometry" (Fetisov).

"Summation of Infinitely Small Quantities" (Natanson).

"What Is Linear Programing?" (Barsov).

3. Published by the School Mathematics Study Group (as vol. IV of "Studies in Mathematics") and available from A. C. Vroman, Inc., 367 South Pasadena Avenue, Pasadena, Calif., 91105.

"Geometry" (Kutuzov).

4. Published by D. C. Heath & Co.

"Convex Figures and Polyhedra" (Lyusternik).

"Eight Lectures on Mathematical Analysis" (Khinchin).

"Geometric Construction in the Plane" (Argunov, Balk).

"Geometry of the Straightedge and Geometry of the Compass" (Zetel').

"Infinite Series" (Markushevich).

"Isoperimetry: Maximal and Minimal Properties of Geometric Figures" (Kryzhanovskii).
"Multicolor Problems" (Dynkin, Uspenskii).
"Probability and Information" (Yaglom and Yaglom).
"Problems in the Theory of Numbers" (Dynkin, Uspenskii).
"Random Walks" (Dynkin, Uspenskii).

5. Published by Holden-Day, Inc., 728 Montgomery Street, San Francisco, Calif., 94111:
"Challenging Mathematical Problems with Elementary Solutions," vol. I: "Combinatorial Analysis" (Yaglom and Yaglom).
"Challenging Mathematical Problems with Elementary Solutions," vol. II: "Various Branches of Mathematics" (Yaglom and Yaglom).

6. Published by Pergamon Press, Inc., New York-London, available from The Macmillan Co., 60 Fifth Avenue, New York, N.Y., 10011:
"Envelopes" (Boltyanskii).
"Shortest Paths" (Lyusternik).
"Successive Approximation" (Vilenkin).
"Systems of Linear Equations" (Margulis).

7. American Geological Institute: "Geology and Earth Sciences Sourcebook for Elementary and Secondary Schools," Holt, Rinehart & Winston, Inc., 383 Madison Avenue, New York, N.Y., 10017.

8. Committee on the Undergraduate Program in Mathematics, Mathematical Association of America, Post Office Box 1024, Berkeley, Calif., 94701:
"Course Guides for the Training of Teachers of Junior High and High School Mathematics."
"Recommendations for the Training of Teachers of Mathematics, A Summary."

9. "Laboratory and Field Studies in Biology, a Source Book for Secondary School," Teacher and student eds., Holt, Rinehart & Winston.

10. "Goals for School Mathematics, the Report of the Cambridge Conference on School Mathematics," Houghton Mifflin Co., 2 Park Street, Boston, Mass., 02107.

11. "The Teaching of Anthropology" (Mandelbaum, Lasker, Albert), University of California Press, Berkeley, Calif., 94720.

12. "Resources for the Teaching of Anthropology" (Mandelbaum, Lasker, Albert), University of California Press.

13. "Laboratory Experiments in General Physiology," American Physiological Society, 9650 Wisconsin Avenue, Washington, D.C., 20014.

14. "Laboratory Experiments in Elementary Human Physiology," American Physiological Society.

15. "Twenty-Six Afternoons of Biology" (Wald, Albersheim, Dowling, Hopkins, Lacks), Addison-Wesley Publishing Co., Inc., Reading, Mass., 01867 (college level).

16. "Novel Experiments in Physics," Committee on Apparatus for Educational Institutions of the American Association of Physics Teachers, American Institute of Physics, 335 East 45th Street, New York, N.Y., 10017.

17. "Berkeley Physics Course," McGraw-Hill Book Co., Inc., 330 West 42d Street, New York, N.Y., 10036:
"Berkeley Physics Course," text, vol. 1.
"Laboratory Physics, Part A: Berkeley Physics Laboratory."

18. Semiconductor Electronics Education Committee Books, Johy Wiley & Sons, Inc., 605 Third Avenue, New York, N.Y., 10016:
"Introduction to Semiconductor Physics" (Adler, Smith, Longini), vol. 1.
"Physical Electronics and Circuit Models of Transistors" (Gray, DeWitt, Boothroyd, Gibbons), vol. 2.
"Elementary Circuit Properties of Transistors" (Searle, Boothroyd, Angelo, Pederson), vol. 3.

19. Elementary Science Study (Educational Services Inc.), Houghton Mifflin Co., 2 Park Street, Boston, Mass., 02107. Inspection packages available February 1965 on:
"Growing Seeds," grades 1–3.
"Behavior of Meal Worms," grades 5–8.
"Kitchen Physics—A Look at Some Properties of Physics," grades 5–8.
"Gases and Airs," grades 5–8.
"Small Things—An Introduction to the Microscopic World," grades 4–6.

APPENDIX 5

SURVEY OF MEMBERS OF THE NATIONAL ACADEMY OF SCIENCES

LIBRARY OF CONGRESS,
LEGISLATIVE REFERENCE SERVICE,
Washington, D.C., August 2, 1965.

To: P. B. Yeager, House Science and Astronautics Committee, Subcommittee on Science, Research and Development.
From: W. H. Donnelly, Science Policy Research Division.
Subject: Information about NAS members.

At our meeting on July 23 you requested information about the colleges where members of the National Academy of Sciences (those elected since 1960) did their undergraduate study.

There is attached a list of the members of the Academy showing the baccalaureate institution for each—except where foreign colleges were involved—and also the current enrollment of these colleges and the type of degree given. This latter information on enrollment and education comes from the Education Directory, 1963–64 on Higher Education published by the Office of Education of DHEW in 1964.

In summary form, one finds the following distribution of these colleges, in terms of their present student body:

Enrollment	NAS members	Percent
Up to 2,000 students	24	12.0
2,000 to 5,000 students	24	12.0
5,000 to 10,000 students	21	10.6
10,000 and over students	88	44.4
Educated abroad	41	20.7
Total	198	

The second added column indicates the highest degree awarded by each institution: (1) is less than a 4-year degree; (2) is a 4-year degree; (3) is 1 year's graduate study; (4) is a Ph. D. degree. The letters indicate type of institution: (b) is liberal arts and general; (c) liberal arts and general and terminal-occupational; (e) and (f) are liberal arts with business or teacher education; (g) is professional only; (h) is professional and teacher preparatory; (j) is liberal arts with one to two professional schools; (k) is liberal arts with more than two professional schools.

Name	Year elected	Baccalaureate institution	Enrollment	Classification
Robert Arnold Alberty	1965	University of Nebraska	10,401	4(k)
Lawrence Hugh Aller	1962	University of California	91,045	4(k)
Herbert Lawrence Anderson	1960	Columbia College	849	2(b)
Thomas Foxen Anderson	1964	California Institute of Technology	1,339	4(g)
Christian Boehmer Anfinsen	1963	Swarthmore	977	3(b)
James Richard Arnold	1964	Princeton	4,196	4(k)
William Archibald Arnold	1962	California Institute of Technology	1,339	4(g)
Daniel Israel Arnon	1961	University of California	91,045	4(k)
Allen Varley Astin	1960	University of Utah	13,448	4(k)
James Gilbert Baker	1965	University of Louisville	6,652	4(k)

APPENDIX 6

Staff Survey of Nonprofit Research Institutes[1]

Coincident with the National Science Foundation hearings, the committee explored the nature and extent of scientific research performed by the various nonprofit research institutes in the United States. A poll of 12 such institutes was taken, asking 2 questions:

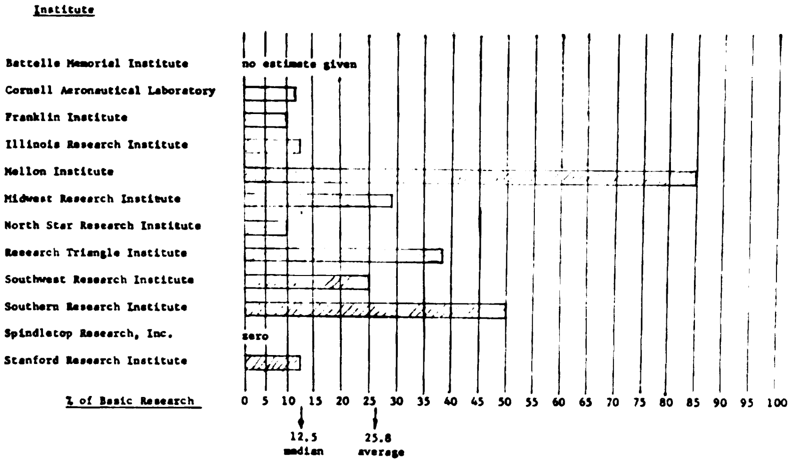
1. What percentage of your research activity do you consider to be basic research?
2. Does your institute at this time have any contract with or does it have a research grant from the National Science Foundation? If so, of what nature and amount? (If you have had such assistance in the past, the same data on it would be useful.)

The results are tabulated in three accompanying charts. Chart No. 1 shows that the proportion of basic research performed by the private institutes varies from 0 to 85 percent of their total research activity, with an average in the vicinity of 25 percent. It is apparent that the institutes operate primarily as contract laboratories in applied research.

Chart No. 1

PERCENTAGE OF BASIC RESEARCH

of the Total Research Activity of 12 Institutes



[1] Staff of the Subcommittee on Science, Research, and Development of the Committee on Science and Astronautics.

Although no uniform precise definition of "basic research" evolved from the inquiry, a generally acceptable interpretation might be that basic research is any research yielding completely new scientific knowledge of lasting value. Many institute directors noted that there is wide latitude among scientists in their concept of basic research as against applied or developmental research. Some preferred to call it fundamental or exploratory research. Battelle Institute declined as a matter of policy to offer a percentage estimate.

The highest estimate—85 percent by the Mellon Institute—is a calculated average of a total program, including independent research supported by endowment funds, reported as 100 percent basic; research supported by Government, 90 percent basic; and research supported by industry, 75 percent basic.

Chart No. 2 shows that 7 of the 12 institutes have received NSF assistance, 5 with current contracts or grants. The NSF criteria for support of nonprofit institutions have been stated by Director Leland J. Haworth, in his reply to committee questions, as follows:

> The Foundation's present policy is to emphasize support of research which also contributes to graduate and postdoctoral education in the sciences. Hence, grants will normally be made to nonprofit institutions only when they can demonstrate a close relationship to such education. However, special consideration will be given when the proposed research is judged to be of exceptional significance or where the institution has unique capabilities.

CHART NO. 2.—*National Science Foundation contracts and grants*

Institute	National Science Foundation funding	Number of projects	Years
Battelle Memorial Institute	$396,191	9	1954–65.
Cornell Aeronautical Laboratory	59,295	1	Current.
Franklin Institute	494,540	9	Current.[1]
Illinois Research Institute	None		
Mellon Institute	570,155	9	Current.[2]
Midwest Research Institute	23,570	4	1958–61.
North Star Research Institute	None		
Research Triangle Institute	52,000	1	1959.
Southwest Research Institute	None		
Southern Research Institute	None		
Spindletop Research, Inc	None		
Stanford Research Institute	162,100	3	1963–65.

[1] Franklin Institute for the past 5 years has received an average of about $225,000 annually in National Science Foundation assistance.

[2] Mellon Institute's annual rate of new National Science Foundation grants and contracts is approximately $95,000.

Chart No. 3 compares each institute's overall proportion of basic research with the degree of National Science Foundation funding. It reveals no direct relationship. For example, the two institutes reporting the largest sums of National Science Foundation con-

tracts and grants—Mellon and Franklin, each around $500,000—estimate their basic research respectively at 85 percent and 10 percent of their total workloads. And the institute reporting the second highest proportion of basic research—Southern at 50 percent—has received no National Science Foundation help at all.

CHART NO. 3.—*Relationship of National Science Foundation support to proportion of institute's basic research program*

Institute	National Science Foundation funding	Percentage of total workload considered to be basic research
Battelle Memorial Institute	$396, 191	No estimate given.
Cornell Aeronautical Laboratory	59, 295	12 percent.
Franklin Institute	494, 540	Average of 10 percent.
Illinois Research Institute	None	10 to 15 percent.
Mellon Institute	570, 155	Average of 85 percent.
Midwest Research Institute	23, 570	25 to 33 percent.
North Star Research Institute	None	10 percent.
Research Triangle Institute	52, 000	38 percent.
Southwest Research Institute	None	25 percent.
Southern Research Institute	None	50 percent.
Spindletop Research, Inc	None	Zero.
Stanford Research Institute	162, 100	10 to 15 percent.

Despite this wide variation in comparison of total programs, the survey confirmed that all of the institute support that comes from National Science Foundation is, in fact, devoted to projects that can be legitimately justified as basic research. This is shown at Franklin Institute where, as already noted, only 10 percent of an annual budget of $13 million is considered to be basic research. Nevertheless, over 90 percent of its National Science Foundation grants—that is, $460,000 out of $494,000—are assigned to the Bartol Research Foundation, which is a Franklin laboratory that is engaged solely in basic research.

The institutional applied research contracts, which comprise their principal workload, are financed wholly from sources other than National Science Foundation.

APPENDIX 7

COMMUNICATIONS TO THE SUBCOMMITTEE ON SCIENCE, RESEARCH, AND DEVELOPMENT

BETHESDA, MD., *April 27, 1965.*

Hon. E. Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development,
House of Representatives, Washington, D.C.

DEAR SIR: I have learned with interest of your subcommittee's control measures, as they are applied to the activities of the U.S. National Science Foundation. Kindly permit me some remarks:

They don't have an ax to grind with anyone in this Foundation. I would like to point out the apparent fact that appropriations and grants have been virtually abolished for private individuals, who intend to approach the Foundation for support of their proposed projects. It looks as if applications from individuals are summarily rejected, unless perhaps the applicant is among the fortunate winners of the Nobel Prize or other financially doted awards. There, additional funds from the Foundation would seem to be quite superfluous.

This situation is obviously infested with discrimination, particularly so, if one considers the origin of the Foundation's financial means: tax money, supplied by industry and citizens, but hardly anything from the often-exempted universities.

Yet, there is frequent evidence that unaffiliated individuals contribute in a much more economic way to the evolution of science (there, the "lone wolf" theory is applicable), than the organized follower of team policy in a university-managed laboratory or in a nonprofit research foundation (here, Parkinson's laws apply).

One source of supporting arguments for the individuals and their projects, for example, provides the correspondence section of the Proceedings of the IRE (now IEEE) of the last 10 years, where scientific and technical papers are printed from both groups of contributors.

It is important to add that individualistic petitioners for grants in most cases are well-qualified scientists. But they may be in circumstantial situations that just don't permit them to join an institution on the favored-son-list of the National Science Foundation in order to get financial support for the pursuance of a scientific idea, which they even might have conceived while working on a project of their profit-eager employer corporation.

An interesting sideline that may help improving this matter can be followed by redefining and by extending the so-called postdoctoral fellowship awards of the NSF to all individuals who can prove to be scientists. One should exercise great care, that this is not done by flashing diplomas, but rather by securing mentor sponsors of the individual's own choice, and who already have contributed their own share to science.

In my own career—I must mention as a supporting argument—I have met Ph. D.'s of long standing who turned out to be more ignorant than a candidate who just passed his bachelor's examinations.

I would appreciate very much to receive your comments.

Sincerely yours,

REINHOLD GERHARZ.

UNIVERSITY OF FLORIDA,
COLLEGE OF ARTS & SCIENCES,
Gainesville, May 3, 1965.

Hon. EMILIO Q. DADDARIO,
House of Representatives,
Washington, D.C.

DEAR MR. DADDARIO: It is with keen interest that many of us look forward to the conclusions of your subcommittee in its consideration of the affairs of the National Science Foundation.

Since there has been, for some time, a rather unfortunate misunderstanding of the role which research plays in universities, it would be the hope of many of us that your subcommittee might, in its conclusions, set matters aright in this context.

To put this in the most succinct possible way, the problem is that of "research versus teaching" as compared to "research and teaching."

Now it is true, of course, that a relatively small number of persons within the general framework of academic activities spend a disproportionate amount of energy and time on research to the detriment of teaching. It is, moreover, true that the young academician is a great deal more loyal to his discipline than to his university today. But in the first instance the number is much smaller than is reputed to be and in the second instance universities today are not comparable in size to what they once were. The academic village of yesterday is the academic metropolis of today. Whether this is good or bad is not very important, and what is really germane is the fact of the situation.

The fact that "teaching loads" are smaller than they were 20 years ago does not mean that "workloads" are lighter. The situation is that most professors (particularly those active in research) have many more duties and a larger share of them than they had earlier.

1. They have a larger number of students to counsel and advise.
2. There are more graduate students whose work they must direct.
3. They are more deeply and frequently concerned with preuniversity curriculums and, at the other end of the spectrum, with postdoctoral "students."
4. Because of the increase in the size of departments, they are more involved in administrative work than earlier.

It is a popular fallacy that the "blame" for this is laid to a surfeit of research funds and vigorous competition for these funds. In some small number of instances this may be so, but colleges of medicine were never more affluent researchwise and health service was never better than is now the case.

To put it mildly, students never had it better. Their teachers are better trained (and this is improving), they are more than ever devoted to their disciplines and they have never had a greater urge to do as well as possible in faculty competition to attract students to their disciplines. Now, at least in the sciences (and hopefully, when there is a National Humanities Foundation), this best of all possible educational situations is due precisely to the fact that funds are available for research for faculty and students.

There has also been a resurgence of criticism against too much teaching by graduate students. The fact of the matter is that if all professors did nothing but teach undergraduate courses then several things would happen: (*a*) there would be no university professor being prepared for the future; (*b*) half of the undergraduates, at least, would have no teachers at all; and (*c*) progress in basic knowledge would come to a disastrously screeching halt.

Now graduate students have been teaching, both here and abroad, almost from the beginning of academic time. This is the way they make a living and this is the way universities have been getting teaching. As a matter of fact, this "practice teaching" is being required for the doctorate in more and more universities. It is not courses in "education" that matter, but the actual business of being faced with a class and being faced with the results of the final grades that counts in making teachers. I could only wish that, at my age and with my experience, I had nearly so much devotion and enthusiasm for spreading the gospel of mathematics as my young colleagues have, who are also my students in graduate courses. They have the passion for doing it, and the vigor to do it with, that many full professors with more experience and more training do not have.

It is clear as the nose on your face, that if graduate students did not teach then there would be no graduate students and, shortly, no professors.

But this is not enough—what the graduate student also needs is some free time for his training as a researcher—this is a part of the job of becoming a professor—and what his professor also needs, time to direct his research and to keep his (the professor's) research going.

At least in the sciences, this is what NSF has been able to do for universities and what would not have been done without NSF.

Taking another right turn, it does not seem to be readily apparent that mathematics and mathematicians move in interstate commerce, and the latter to a smaller extent in international commerce. The State of Florida is quite obviously concerned with the training of citrus agronomists and the State of New Jersey is not. But Florida is not vitally concerned with training petroleum geologists and Texas is greatly concerned. However, every State uses professors of mathematics and it does not make much difference in what State they are trained, if they are well trained. The point here is that the Federal Government is concerned (or should be) to a greater extent than any State (or every State) in training mathematicians. Thus far, it is to the greatest extent that NSF has been so helpful. This is not to say that other Federal agencies have not helped, but within a rather limited and specialized part of mathematics—mainly what is useful to the agency concerned. Mathematics and the training of mathematicians is a Federal concern and NSF has done an excellent job. Looking at it another way, the expected 1970 student boom is unexpected in the sense that it seems now likely to be far larger than first anticipated. Clearly, the individual States cannot possibly undertake to prepare all of the needed college teachers and university teachers of mathematics, and without NSF, neither can the Federal Government.

To put the above in its most practical and immediate fashion, perhaps your subcommittee could ascertain the origin of each Ph. D. mathematician now in academic life in Connecticut.

Aside from the English language, mathematics is the most used and the most useful of all disciplines in the sciences, and this is coming to be so in the humanities. No field, from agronomy to zoology (and including economics, genetics, psychology, and so on) fails to use some part of mathematics. In the vast majority of instances, almost all of the mathematics that is learned is taught in departments of mathematics. This is where the engineering student and the business administration student both learn mathematics. Here, the department of mathematics has the largest student load and the largest faculty of any department in the college of arts and sciences (probably in the university). Yet (and I do not think this unreasonable) the legislators in the State are a great deal more concerned with agriculture and dairy farming, and these areas are far better funded. Actually, I think that the cost per student credit is less in mathematics than in any other discipline at this university. This would not seem peculiar to this State and is probably so in general in State institutions. However, we must have more and better trained mathematicians, and more and better mathematics, and it seems clear that this situation can only be brought about by Federal assistance. And if this is to get to mathematics the initial grant must be made to mathematics.

The Congress and the administration are both very wisely concerned with the immediate practical goals of scientific research. I think, and I hope that your subcommittee might agree, that the most important of these is the preparation of scientists, because, whatever we may have now in scientific and technological know-how, it will not be worth having if we are unable to continue it and to exploit it a decade hence. While making NSF the immediate university source of research funds as a means of accomplishing this end may not, at first, seem to be the best way; it seems to be a fact that over the past 15 years this is how it has happened, particularly for mathematics. And foremost among the reasons for the effectiveness of NSF is the point just made, that mathematics and mathematicians move in interstate commerce. It is the Federal Government that can best ascertain the needs and make the allotments, via NSF.

As long as this letter is, it is merely a brief account, and Dr. Milton Rose of NSF (MPE) can give you a far better account than is contained here.

Very cordially yours,

ALEXANDER DONIPHAN WALLACE.

HIGHLAND PARK, N.J., *May 7, 1965.*

Senator CLIFFORD P. CASE,
Senate Office Building,
Washington, D.C.

DEAR SENATOR CASE: The removal of some science support from the decision-making power of Federal agencies and its replacement by block institutional grants is a critical requirement for the advance and competitive position of American research as well as education.

In our graduate schools of engineering we feel, and we know that our colleagues in the science schools feel, that—

(1) Action on research ideas, and therefore the transmittal of the resultant body of knowledge to the graduate student, is delayed and, in two-thirds of the cases suppressed by the needs to translate them into formal research projects subject to the approval of agencies with the delaying, but necessary circulation through committees.

(2) Guidance of research, faculty, and graduate body is disastrously removed from the authority of the school, resulting in disjointed and exaggerated authority of individuals proficient or lucky in project funding promotion.

(3) We find ourselves distracted and occupied by constant project generating, defending, and supervising activities which are badly encroaching on our teaching and searching life.

(4) The topics selected are unrealistically removed from and unmanageably disjointed in the body of knowledge and common search germane to a live number of persons with specific gifts in teaching and research.

I respectfully urge you to investigate and, if you find our feelings substantiated, strongly pursue changes in support policy, as advocated by the Purdue speech of the new president of the academy, Dr. F. Seitz. The new, unusual, and fortuitous availability of such a man in a full-time long term should be welcomed by active listening to his advice.

As engineers we wish, however, to stress two points implied in the address that—

(1) The project system should not be abandoned, only reduced in favor of block grants. The reason for this is the need for the university to remain formally aware of frontiers of requirements related to national welfare in the broadest sense, including defense. These needs have led to the present system and should not be disregarded in spite of the described shortcomings.

(2) The grant system should extend to the humanities. We are not entitled to prejudge the relative merits of engineering, the physical sciences, and the humanities in the light of the desires and wants of the future.

Sincerely,

NORBERT J. KREIDL,
Professor of Ceramics, Rutgers University.

UNIVERSITY OF SOUTHWESTERN LOUISIANA,
Lafayette, La., May 11, 1965.

Re review of the National Science Foundation by the Subcommittee on Science, Research, and Development.

Representative EMILIO Q. DADDARIO,
U.S. House of Representatives,
Washington, D.C.

DEAR MR. DADDARIO: I am interested in an area of higher education which is being neglected by the National Science Foundation; specifically the master of science program. The graduate trainee program, in particular, is limited to schools with Ph. D. programs. Other agencies follow a similar policy and as a result master of science programs are, for all practical purposes, being put out of business. This is happening because, without funds, we cannot compete with the Ph. D. schools for graduate students.

Failure to support master of science programs is producing such results as:

1. More schools than we need are starting Ph. D. programs in order to obtain funds. This is true particularly in chemistry where there are insufficient students to staff at least 135 Ph. D.-granting institutions.

2. College teacher training programs are best done at the master of science level. If the schools are not supported the training will cease for the Ph. D.-granting institutions have neither the time nor the interest to engage in such work.

3. If a large institution of about 2,000 to 3,000 students as a minimum figure cannot offer the M.S. degree it cannot staff its faculty with Ph. D.'s. Many candidates will not accept positions in which their full time must be devoted to elementary work, such as general chemistry, unless they are offered compensatory work at an advanced (M.S.) level.

I hope that this information will be of some value to you.

If I can be of any further information let me know. However, there is no need to add to the work of your office by acknowledging this letter.

Sincerely yours,

C. A. McKenzie,
Head, Chemistry Department.

Loma Linda University,
Laboratory of Neurological Research,
Los Angeles, Calif., May 24, 1965.

Representative E. Q. Daddario,
Subcommittee on Science, Research, and Development,
House of Representatives, Washington, D.C.

Dear Representative Daddario: As a teacher and research director in one of the smaller medical institutions in our country I wish to go on record as a strong supporter of the methods employed by the National Science Foundation in the consideration, review, and awarding of grants for research in biology and medicine.

As one who has some knowledge of the manner in which Federal funds are spent through the various granting agencies, I suggest that the National Science Foundation has consistently shown a better record for its budget than many of the other Federal granting agencies. I feel this has come about because of the Foundation's reviewing system, which tends to use a greater number of individual specialists for the subject under consideration, rather than committees (which admittedly are made up of exceedingly competent scholars, but which often tend to become "clubs" frequently composed of a sampling from a restricted number of our more learned institutions).

I have always found the reviews of the National Science Foundation in my particular area of interest to be very fair, and more dependent upon scholarship and production than the reviews by many other Federal granting agencies.

Sincerely yours,

Findlay E. Russell,
Director of Laboratory.

Pittsburgh, Pa., *May 25, 1965.*

Hon. Emilio Daddario,
House Office Building,
Washington, D.C.

Dear Congressman Daddario: The Chemical and Engineering News issue of May 3, 1965, contained an article in which it was stated that your House Subcommittee on Science, Research, and Technology will shortly probe the National Science Foundation.

This was of great interest to me both as an individual translator and as president pro tem of the newly formed American Society of Scientific & Engineering Translators (ASSET).

It is a known fact that the National Science Foundation has been getting its scientific and technical translation work done in Israel, Poland, and Yugoslavia. It is my understanding that one of the reasons given for having this material translated in the above-mentioned countries is that there is not enough competent translation talent available in the United States to satisfy NSF's requirements.

I have exchanged many letters with other translators in the United States during the past year or so and most of them informed me that they had no knowledge of the fact that the National Science Foundation was engaged in translation activities. On the other hand, I have received letters from translators who have written to the NSF about doing translation work for them with the end result that they were referred to me and other translators. As far as I know, none of them ever received any translation assignments from NSF.

This may not be important in itself, but I am of the considered opinion that it would be rather difficult to dispute the statement that research and translation activities go hand in hand. If this is true, then it is equally true that the exporting of translation work to foreign countries is detrimental to the best interests of the United States and to the practicing translators who earn their livelihood in this country.

One of the purposes of ASSET is the training of competent scientific and technical translators. ASSET believes that our Nation should at all times have a ready supply of translators who can satisfy the requirements of both Government and industry. It is rather difficult to sell a person on a translation career when so much work is leaving the country to be done abroad.

I am quite certain that there are enough competent translators in the United States who would be willing and able to handle any type of translation assignment that NSF would require.

I should be deeply grateful if you could furnish me with a final report of your investigation.

Needless to say, ASSET stands ready to cooperate with your committee in any way.

Very truly yours,

A. J. ORLUK.

OBERLIN COLLEGE,
May 25, 1965.

Interoffice to: Fred Foreman.
From: William Athony Gordon.
Subject: Letter from Representative Mosher regarding NSF.

The training of new generations of scientists is an important area where NSF has been able to exert a strong and beneficial influence. I should like to see this influence extended, particularly with reference to undergraduate training. In contrast to graduate training of scientists, which seems to be well supported in a number of direct and indirect ways, undergraduate training offers many opportunities for increased support. We have been successful ourselves in gaining help from NSF, but my impression from talking to NSF personnel and from published reports is that are too many good undergraduate education programs which cannot be supported by NSF purely because of lack of funding for the undergraduate level. The undergraduate education in the Sciences Section of NSF has two programs from which our department is at present gaining strength and I should like to see this kind of support given to many more institutions than can now be offered it. The two programs that I have in mind are the undergraduate research participation program and the undergraduate instructional scientific equipment program. These programs are being of great help to us in our role of producing graduates who will go on to advanced training in science at other institutions.

AMERICAN INSTITUTE OF PHYSICS,
New York N.Y., May 28, 1965.

Hon. EMILIO Q. DADDARIO,
Longworth House Office Building,
Washington, D.C.

DEAR SIR: Your remarks after the luncheon meeting for science writers, April 27, have raised some questions that interest the American Institute of Physics. We take this opportunity to present our thought on the relations of international scientific activities to the purpose of the National Science Foundation, but we realize that our comments here do not reflect full knowledge of the discussions that have already taken place or of the conclusions reached.

The National Science Foundation is devoted to the support of "U.S. science." We believe that what is good for U.S. science is often indistinguishable from what is good for international science, as the participation of two NSF programs so eloquently demonstrates—the International Indian Ocean Expedition and the International Year of the Quiet Sun.

Many persons acknowledge the foreign origins of much of U.S. science, but we believe that the continued growth of our science needs a continued exchange of ideas between our country and others, and increased opportunities for those who work outside their own country to retain their professional standing. We strongly endorse the visiting scientist programs such as those under the

Fulbright-Hays Act and under NSF. These programs involve individuals for only a year or so.

Our correspondence with U.S. physicists on long-term appointments in developing countries shows that they may have seriously endangered their positions on the academic ladder at home. We believe both U.S. and world science would benefit from measures that encourage qualified scientists to enter foreign service and that help them to retain their professional standing. We endorse programs that link research programs at foreign universities to those in the United States.

The provision of travel grants to attend scientific conferences in nearby countries is useful. NSF does provide travel grants, but we understand that it is difficult for those on long assignments to obtain awards.

As you know, a number of highly qualified alien scientists work at National or Government laboratories, such as Brookhaven or the Bureau of Standards, or at universities. These organizations would greatly benefit if they were able to send qualified alien scientists to conferences abroad, because they have unique qualifications or unusual language facilities. However, we understand that travel grants for such purposes are restricted to U.S. citizens. We believe these restrictions should be reviewed.

We are not concerned that there my be an occasional overlapping of international responsibilities between the National Science Foundation and the National Academy of Sciences, but only that the closest cooperation between the two agencies serve nationally the broader interests of international science.

Our outlook from the Institute, which works in behalf of our several professional societies, cannot encompass all science, but we welcome further discussion on these or other topics if the need arises.

Sincerely yours,

VAN ZANDT WILLIAMS,
Director.
F. BEHN RIGGS, JR.,
Director, Information Center on International Physics Activities.

OBERLIN COLLEGE,
DEPARTMENT OF PSYCHOLOGY,
Oberlin, Ohio, May 30, 1965.

Hon. CHARLES A. MOSHER,
Representative to Congress,
Longworth Building, Washington, D.C.

DEAR CHUCK: Thank you for soliciting comments on the National Science Foundation in connection with the Daddario subcommittee study.

While much can be said regarding the accomplishments of NSF, let me dwell on just a few of its outcomes that have impressed me a great deal.

1. Through its undergraduate research participation program it has made it possible for colleges to provide much more meaningful training of undergraduate students majoring in the sciences. While science departments have always had the objective of imparting good training along research lines, very limited budgets made it impossible for most colleges to do more than make a gesture in the direction of sound training. Today, if a department can present evidence that it knows how to make maximum use of such funds, it can compete with other departments for the support needed to upgrade instruction in the sciences. As a result of this program our majors are today receiving very sophisticated research training compared to what Fritz was able to obtain with us just a few years ago.

2. Through its undergraduate instructional equipment program it has made it possible to obtain apparatus which gears in nicely with the current emphasis upon personal participation in meaningful research as an integral part of the instructional program. A grant from NSF, when matched with an equal sum of money by the trustees of Oberlin College, permitted us to purchase $25,000 worth of apparatus which has given us a real boost in meeting modern needs for superior education in the sciences.

3. Through grants made to certain disciplines which wish to make a comprehensive self-study of means of improving instruction at both the high school and college level a great deal has been learned about how to upgrade teaching procedures.

4. Through institutes for high school and college teachers it has helped retrain those teachers who, through no fault of their own, have become somewhat rusty. Although it is difficult to measure the impact of this kind of a program I am confident that thousands of students are receiving better instruction as a result of this kind of program.

For these reason I am persuaded that NSF has made a real difference and that the difference is all for the good.

Sincerely,

RALPH H. TURNER, *Chairman.*

OBERLIN COLLEGE,
June 1, 1965.

Interoffice to: Fred Foreman.
From: J. L. Powell.
Subject: National Science Foundation.

DEAR FRED: These remarks are in response to the letter you received from Representative Mosher asking for suggestions concerning the NSF.

The importance of the Foundation to science in the United States cannot be overemphasized. Basic research in this country depends on the continued existence and expansion of the Foundation. I feel that all too often, the importance of basic research is judged more on the titles of present research projects than on the long-range benefits of such projects. It seems to me that the basic philosophy of Government support of basic research ought to be a realization that basic research yields benefits which are very often not foreseen when the research begins. There are countless examples which prove that this is the case.

Now a word about the significance of the NSF to science departments at small liberal arts colleges such as Oberlin. Such institutions by virtue of their size and educational philosophy do not have the funds available for the support of the sciences that the large universities with graduate schools have. On the other hand, most scientists, and I include all teachers of science, are and should be interested in doing research. I believe that research and the proper teaching of science are not only compatible but that research is necessary for the best teaching of science. The small colleges, then, should be trying to attract scientists who are oriented toward research as well as teaching. Yet the costs of scientific research are mounting, and this is nowhere better shown than in our field of geology where geologists have now begun to use such instruments as mass spectrometers, electron probes, and computers. This tends to direct the best scientists toward the larger institutions where more funds for research are available. It is at this point that the Foundation becomes important, because it represents a source of funds for the support of science that is available to the large and small institution alike. Were it not for the Foundation and other Government organizations such as AEC and NIH, basic scientific research at small institutions would in my opinion rapidly dwindle away and almost become nonexistent. Certainly the small institutions would not be able to attract scientists interested in both research and teaching.

Using my own case as a rather typical example, when I left graduate school I knew quite definitely that I wanted to do research in isotope geology with a mass spectrometer, and that I liked the small college atmosphere. A person in my position at that time would probably not have come to Oberlin if there had been no possibility of financial support in research from the NSF.

All of this makes clear the importance of the Foundation to science at institutions such as Oberlin. My only criticism of the Foundation is that in the past it has perhaps tended to aid the larger and more wealthy schools proportionately more than the smaller schools, and that it may have concentrated its support on the east and west coasts. I believe it is vital that the Foundation be expanded, and that it give increasing attention to a more equal distribution of its funds, both on the basis of geography and on the basis of the size and quality of the institution seeking funds. I am aware that steps in this direction have been taken recently by the Foundation, but I urge that these steps be continued and furthered.

Sincerely yours,

JAMES L. POWELL,
Assistant Professor of Geology.

OBERLIN COLLEGE,
DEPARTMENT OF GEOLOGY,
Oberlin, Ohio, June 3, 1965.

Hon. CHARLES A. MOSHER,
House of Representatives, Washington, D.C.

DEAR CHARLES: Your letter of the 21st came at a busy time but am very pleased that you have given the staff a chance to present their views on the NSF and its importance to basic science in an undergraduate college. Enclosed are the reports of Dr. William A. Gordon, paleontologist and Dr. James L. Powell, geochemist, the other two teaching members of our staff.

Next year is my last year of teaching at Oberlin and my viewpoint may be a bit different income respects to my young colleagues.

We, Mrs. Kathryn Clisby and I, have had faculty grants from the Earth Science Division of the NSF since it started in 1956. In fact it is, I understand, through Dr. Paul B. Sears and his interest in our work on the pleistocene sediments and their pollen that the Earth Science Division was initiated. These last 2 years geology has had grants from the NSF for undergraduate research. For the next 2 years we have both an undergraduate research participation and also an undergraduate instructional scientific grant. These grants will be of great help to the students and to the geology department.

Students will be given a chance at the undergraduate level to start research under good supervision. An early introduction to research will help to eliminate those who do not have an aptitude for it and encourage and give direction and impetus to those who find it stimulating and rewarding.

The staff too will be encouraged to continue in active research and this I think and hope will help teach in the department as well as benefit those engaged in research and also add to the basic knowledge in the science itself.

There are two problems that will need to be watched. Too much emphasis on research may lead to less interest and time given to teaching. This is already a problem in the graduate schools and may become one in the colleges. If this happened it would be most unfortunate for the students, the colleges, and the country itself.

The other problem is one that has impressed itself on me this last year or so and it is relative to sophisticated instrumentation. These require a lot of attention at the technical level. Many good men who have the mental ability and push for research do not have the skills needed to keep these machines running efficiently and accurately, those that do find this work very time consuming. The universities have skilled technicians but even a relatively rich school like Oberlin does not supply such help. I do not know what the answer to this problem is but it is there.

I hope the above and the letters from my colleagues are of help to you and the Daddario subcommittee.

Sincerely,

FRED FOREMAN, *Chairman.*

ROOSEVELT UNIVERSITY,
OFFICE OF THE PRESIDENT,
Chicago, Ill., June 7, 1965.

Hon. EMILIO QUINCY DADDARIO,
Subcommittee Chairman, Committee on Science and Astronautics,
House Office Building, Washington, D.C.

DEAR MR. DADDARIO: I concur completely with Professor Guthmann's analysis of the benefits to Roosevelt University of the National Science Foundation's program. The enthusiasm generated by the grant awarded to the chemistry department has stimulated other departments of the university as well.

It is particularly in connection with schools like ours, not blessed with large endowments, that the impact of this program becomes especially significant. We would hope that your committee considers it appropriate to emphasize the undergraduate aspects of this program for the benefit of the many liberal arts colleges who turn out the majority of the students going on to graduate work in science. Stimulation afforded in this area would insure the flow of scientifically trained personnel where it is most needed on the graduate level.

Respectfully yours,

ROLF A. WEIL, *Acting President.*

ROOSEVELT UNIVERSITY,
DEPARTMENT OF CHEMISTRY,
Chicago, Ill., June 7, 1965.

Representative EMILIO Q. DADDARIO,
Subcommittee Chairman, Committee on Science and Astronautics,
New House Office Building, Washington, D.C.

DEAR CONGRESSMAN DADDARIO: It is our understanding that your committee is looking into the operation of the National Science Foundation.

It might be of interest to you to know of one of the concrete benefits Roosevelt University has realized from the National Science Foundation. I speak, in particular, of the undergraduate research project. We have had one such grant and have found that the enthusiasm that generated in the three students who participated extended to other students as well and the idea that they would be able to apply some of the chemistry that they had been learning as undergraduates was most significant to them. All three of the students involved are now accepted at graduate schools.

I think the point we would like most to make is that research not only accomplished its own ends but served as a means of sharpening the talents of the students involved prior to their commitment to graduate school. This, in itself, we believe could be a significant contribution to this program. We do hope that your committee will see fit to encourage these aspects particularly.

Another program in which we have been involved, and which we believe should also be enthusiastically supported, is the program involving the upgrading of high school teachers to institutes. We have an in-service institute and have had an opportunity to notice the great need for further training in chemistry for teachers who are currently teaching chemistry. This, too, is a program which needs support and encouragement.

Respectfully yours,

WALTER S. GUTHMANN,
Acting Chairman.

ROCHESTER, N.Y., *June 7, 1965.*

Representative EMILIO Q. DADDARIO,
Congress of the United States,
Washington, D.C.

DEAR REPRESENTATIVE DADDARIO: Because of your considerable knowledge and effort in the critical field of review looking into the relation of fundamental research and public funding I would like to submit for your consideration the copy of a letter to Senator Case, of New Jersey.

Many of us feel strongly, with deep apprehension of the impact on education and welfare, about this issue. We should greatly value your inspection and support of the ideas presented and the many people we believe are sharing these feelings of concern.

Sincerely,

NORBERT J. KREIDL,
Professor of Ceramics,
Rutgers State University.

OBERLIN COLLEGE,
DEPARTMENT OF BIOLOGY,
Oberlin, Ohio, June 9, 1965.

Hon. CHARLES A. MOSHER,
Longworth Building, Washington, D.C.

DEAR CHUCK: You may be assured I gave your letter of May 21 relating to your membership on the Daddario subcommittee and the projected investigation of the Natioinal Science Foundation the attention it deserved. We discussed the letter in staff meeting. Incidentally all were pleased that you were on this committee.

I, myself, do not have any particular wisdom to send you relating to present policies of the National Science Foundation. George Langeler mentioned that it had come to his attention that there was some feeling in the National Science Foundation that project basic research grants should be awarded on a matching basis with a cash contribution coming from the institution. This would put terrible strain on the smaller institutions who have a very difficult time meeting the academic budget to say nothing about sponsored research to benefit the scholarly development of the faculty. George promised that he would write

you in more detail about it when he was sure of his facts. This is something you might keep in mind, however.

Highest regards.

GEORGE T. SCOTT, *Chairman.*

OBERLIN COLLEGE,
DEPARTMENT OF CHEMISTRY,
Oberlin, Ohio, June 11, 1965.

Hon. CHARLES A. MOSHER,
Longworth Building, Washington, D.C.

DEAR CHUCK: Thank you for your invitation to comment on the National Science Foundation. We discussed it in a departmental meeting and have been in surprisingly good agreement.

The programs and policies of the National Science Foundation has evolved over the years in a constructive way. It has initiated and explored new programs and has shown itself responsive to changing needs. The Foundation has modified its procedures as experience indicated. It has kept its principal goals in sight and has held recipients of grants to the objectives of the grants, but it has also encouraged flexibility and experimentation in procedures for reaching goals.

The major moves of the Foundation have been appropriate ones. Some in our department might favor more rapid changes in focus of the programs but all of us agree that the moves of the Foundation have been in the right directions. Several have suggested that what the Foundation needs most is more money, since the Foundation has an impressive history of achievement.

Sincerely yours,

L. E. STEINER, *Chairman.*

[Telegrams]

GAINESVILLE, FLA., *June 22, 1965.*

EMILIO Q. DADDARIO,
Subcommittee on Science, Research, and Development,
House of Representatives, Washington, D.C.:

The National Science Foundation has been doing a very effective job in administering research funds in mathematics aimed toward the graduate education of critically needed mathematicians and applied mathematicians. I commend them for the particular way they are now operating.

JOHN E. MAXFIELD,
Chairman, Department of Mathematics,
University of Florida.

TALLAHASSEE, FLA., *June 24, 1965.*

Hon. E. Q. DADDARIO,
House of Representatives, Science and Astronautics Committee,
Washington, D.C.

Education of mathematicians and applied mathematicians sorely curtailed by lack of funds for research support.

O. G. HARROLD,
Chairman, Department of Mathematics,
Florida State University.

NEW MEXICO STATE UNIVERSITY,
COLLEGE OF ARTS AND SCIENCES,
University Park, N. Mex., June 28, 1965.

Representative E. Q. DADDARIO,
House Office Building, Washington, D.C.

DEAR SIR: I hope you do not receive this letter as if it were an ordinary petition, signed by people who like to have their names on petitions. It is, rather, a letter which we are sending to express our common concern about the relationship between the National Science Foundation and the scientific community.

In your present investigation of the Foundation, we want you to know of our confidence in that organization and in the officials who are charged with its management. And we speak from experience, for each of us has worked with the Foundation, our total experience as a group involving research contracts, fellowships, educational grants, summer and winter institutes at all levels, advisory committees to the Foundation, etc.

We wish to stress the importance of scientific research and what that research can do for our society. In education and in research, it is a necessity—not a convenience—to be able to pursue one's work with a large amount of freedom. Unduly restrictive barriers, financial or otherwise, can inhibit creative inquiry.

The National Science Foundation is managed by people who understand this. While we know that your inquiry will be conducted in all fairness, and while we understand very well the duty Congress has to regulate Government agencies, we hope that the National Science Foundation may continue to be trusted to further the cause of science without any new restrictive laws, regulations, or procedures.

Sincerely yours,

Robert J. Wisner, Associate Professor of Mathematics; Paul K. Garlick, NSF Fellow; J. Mack Adams, Assistance Professor of Mathematics; Franklin D. Rich, NSF Institute Instructor; Jack R. Porter, NSF Fellow; Carol L. Walker, Assistant Professor of Mathematics; Edward D. Gaughan, Assistant Professor of Mathematics; Louis Solomon, Associate Professor of Mathematics; Donald Cook, NSF Institute Instructor; William G. Calton, NSF Fellow; Chiev Khus, NSF Institute Instructor; Larry D. Parker, NSF Fellow; John B. Giever, Professor of Mathematics; Conrad McKnight, NSF Institute Instructor; John D. Thomas, Assistant Professor of Mathematics; Elbert A. Walker, Professor of Mathematics.

CHARLOTTESVILLE, VA., *July 12, 1965.*

Hon. EMILIO DADDARIO,
Chairman, House Science Subcommittee,
House Office Building,
Washington, D.C.

DEAR SIR: I saw several announcements recently of your interest in basic research. I was graduated many years ago from MIT and have spent most of the time since then in research and development. I have filed more than 1,000 of my inventions in the Patent Office, in many different fields. I am equally interested in basic research and I have seen many original conceptions of mine later develop into highly important and valuable discoveries. In order to be more specific I am enclosing a list of my issued patents and a partial list of various originations.

My experience with various organizations such as the National Science Foundation, Office of Naval Research, and others convinces me that something is radically wrong in our Government-sponsored research program. Some years ago a person in ONR having charge of granting basic research contracts told me that he could not give me a contract since my proposed research would have practical applications.

If the NSF policy is the same as it was several years ago it badly needs overhauling. They required that the research worker have substantial amounts of laboratory equipment and also access to funds, and other requirements which would completely eliminate many brilliant scientists from participating. Often the more brilliant the scientists the less likely it is that he can meet the hardware and other requirements of the NSF. The contracts should be awarded on the basis of the originality and industriousness of the scientists and not on the amount of bricks and mortar and other equipment which he can corral. A really capable person can do a tremendous amount of basic research with remarkably little equipment. He should be furnished the equipment regardless of whether he is operating independently or is connected with an institution.

Another great weakness of the past policy is the interminable delay between the date of filing a research proposal and the final decision may be a year later. This is due to shipping the proposal all over the country to various "experts" who, in my opinion, cannot collectively come to any wiser decision than a really capable person who could decide in a matter of weeks. It is of vital importance to select very capable people to pass on research proposals and to give them authority to make quick decisions. When one looks at the worthless and sometimes even silly contracts which frequently have been awarded I am convinced that a few well-paid and highly informed specialists in various fields can do a much better and far faster job of selecting really important research projects than has been done under the past system.

I am not now looking for research contracts for reasons which I have indicated. I would, however, like to see our sponsored research set up on a more effective basis because I am certain that it can be done. I have a very large backlog of basic research ideas recorded in my notes and, if my past experience is any guide, quite a few of them will eventually be brought out by someone else, perhaps 10 or 20 years from now. Judging from past experience some of them will be of outstanding importance, but why delay discovery when it is not at all necessary?

I have met some scientists who have developed a certain reputation sometimes based on standards which are not valid. Some of them have much more reputation than originality and the latter is the one indispensable in research. I believe that it is highly important to avoid such people and to turn over the direction of NSF, ONR, and other organizations to people who really understand the creative, highly imaginative type of research worker. There has been a decided dearth of such understanding in the past.

Very truly yours,

A. G. THOMAS.

OBERLIN COLLEGE,
DEPARTMENT OF PHYSICS,
Oberlin, Ohio, July 26, 1965.

Hon. CHARLES A. MOSHER,
House of Representatives, Washington, D.C.

DEAR CHUCK: I am sorry to have put off so long answering your letter about the NSF hearings. What follows is a somewhat random collection of remarks and impressions.

In general, it seems to me that the NSF has done a fine job of providing excellent support for basic science. With the stupendous press agentry of NASA and, to a lesser extent, of the AEC and the NIH, it is remarkable that Congress and the NSF have been able to build up an impressive level of well-administered support. One may quibble over some things—I, for one, would like to see all NSF graduate fellowship winners really free to choose their schools, as opposed to the current situation with the politically expedient "cooperative" fellowships—and there have been one or two bloopers such as the Mohole business and the AIB fuss, but on the whole the record has been impressive.

The "institutional grants for excellence" proposed last year are evidence that that Foundation is seriously concerned about places such as Oberlin and with the up-and-coming State universities. As you know, we have been able to get summer (and some term-time) research participation grants, and matching grants for equipment. At the moment we have hopes of substantial grants for science departments from the Sloan Foundation and from the Research Corp., but, in the long run, support for thriving research and teaching at a place like this will have to come, in large measure, from the NSF. In the last few years, places such as Oberlin have been going through a quiet but far-reaching revolution in the science departments. Even so, we cannot now, nor are we likely to be able to, compete for NSF money on the same terms as Harvard, Case, MIT, or even Ohio State. Therefore I hope the various programs within the NSF aimed at promoting good science at smaller places will be continued and strengthened. I hope that Trustee Mosher will urge Congressman Mosher to press for more outright grants as opposed to matching grants.

I am enclosing some Xerox copies of some "News and comments" sections from Science, the weekly journal of the American Association for the Advancement of Science. Greenberg, Walsh, and the others who write that column seem to me to be both politically astute and scientifically aware. They do a fine job of interpreting the political pressures to us scientists in the hinterlands, and I suspect that you and your colleagues might find occasionally illuminating pieces there as well. No doubt the last thing in the world you want at this point is a suggestion that you subscribe to one more periodical, but perhaps one of your minions in your efficient office could scan each week's copy for interesting articles as well as for significant items in the "news and comment" section. If you wish, I could attempt something of the sort here—sending copies of likely material—but it might be somewhat faster if done in your own office.

I'm not at all sure that any of this has been of any help to you, but I appreciate your taking the time to get opinions from chairmen of the science departments here.

With best wishes,

DAVID L. ANDERSON, *Chairman.*

UNIVERSITY OF ILLINOIS,
Urbana, Ill., July 29, 1965.

Mr. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development, Rayburn House Office Building, Washington, D.C.

DEAR MR. DADDARIO: From a number of sources I have learned of your subcommittee's consideration of the activities of the National Science Foundation over the past 15 years, and of the informed and sympathetic attention you have given to the role of the social sciences in the Foundation's work. As an anthropologist dedicated to the study of the mystery that is man, I find this especially heartening. As you know, anthropology has enjoyed the support of the Foundation almost since its establishment, and I believe my colleagues around the country would agree that this has been a crucial factor in the rapid growth and maturation of the discipline during the past 15 years. The future of my own field as well as that of our sister disciplines in the other social sciences depends in large measure on the continued and increased support of the Foundation. Thus, I cannot but applaud congressional concern to understand both the nature and the needs of the social sciences.

I might add that during 7 years of residence in Washington, from 1950 to 1957, and after that period as well, I have followed closely the fate of the Foundation, and particularly the growth of the social sciences in its work. I have also served on the Advisory Panel in Anthropology and on numerous ad hoc committees. This total experience has convinced me that the Foundation and the able men who serve it is the most vital and catalytic scientific institution in the Nation. It can and should serve increasingly well all the sciences, including those whose concern is man himself.

Sincerely,

JOSEPH B. CASAGRANDE,
Head, Department of Anthropology.

SWARTHMORE COLLEGE,
DEPARTMENT OF POLITICAL SCIENCE,
Swarthmore, Pa., July 29, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development, Rayburn House Office Building, Washington, D.C.

DEAR CONGRESSMAN DADDARIO: I note with interest that your subcommittee of the Committee on Science and Astronautics, in reviewing the work of the National Science Foundation, has been giving some attention to the needs of the social sciences. Feeling as I do that these areas of research and study have tremendously important contributions to make to the national welfare, I am delighted that you are giving sympathetic attention to their problems.

Sincerely yours,

J. ROLAND PENNOCK, *Chairman.*

CONGRESS OF THE UNITED STATES,
HOUSE OF REPRESENTATIVES,
Washington, D.C., July 29, 1965.

Hon. EMILIO DADDARIO,
Chairman, Science, Research, and Development Subcommittee, Science and Astronautics Committee, House of Representatives, Washington, D.C.

DEAR MR. CHAIRMAN: I believe that it is necessary that the National Science Foundation should change its policy and provide more grants to the social sciences.

I am fully aware that the National Science Foundation has done fine and constructive work; however, I strongly believe and urge that more grants should be issued by the National Science Foundation in the field of social sciences, such as economics, sociology, political science, and others. (This is not meant to refer to the arts and humanities, including art, music and literature, which are provided for in the National Arts and Humanities Foundation bill.)

I was surprised and dismayed to discover that in the list of NSF fellowship programs, there are 103 fields of specialization in engineering, physical, psychological, life, and medical and mathematical sciences, but only 10 in the social sciences. I believe that the social science fellowship grants should be at least doubled by the National Science Foundation—from 10 to 20 percent. Certainly

the 103 subjects are very valuable to our Nation, but other fields are also important—one of them being the social sciences. In addition, I believe that research grants should be substantially increased by NSF in social science subjects. This increase should not be made at the price of other fields, but provided by higher Federal appropriations.

Certainly, a great deal of good would result from such a revision, in economics, sociology, and political science—some of the social sciences.

So many Americans lack even a basic understanding of economics, a field that affects all of us very much. Just think of the broad and tremendous affect these programs have on our daily lives: Taxes, Federal spending, foreign aid and balance of payments. The Kennedy round on tariffs will take place in September and will have a heavy impact on our economy in the vital areas of imports and exports. But how many people understand this program?

Another area in the field of economics that more people should understand is the surplus farm products problem. Still another is the effect of more people leaving the farms for urban and suburban areas.

Another vital area that requires increased attention is sociology—the study of human groups. As our society becomes more complex, greater study is necessary of man and his problems. Above all, practical solutions must be found.

There is also a very definite need for more knowledge and understanding in the field of political science. Our citizens should be aware of how our Government functions and what its problems and goals are. With increased knowledge, they could improve Government.

I must say that the National Science Foundation does help many. Since January 1963, when I assumed office, Rutgers—the State university has received $5,910,726 in NSF grants. These grants have provided great help to scientific and technical projects, as well as aiding our teachers by special training.

I appreciate any considerations you may give these views. Thank you very much for your cooperation in this matter.

Best personal regards.

Cordially yours,

EDWARD J. PATTEN.

UNIVERSITY OF WISCONSIN,

Madison, Wis., August 2, 1965.

Hon. EMILIO Q. DADDARIO,
Subcommittee on Science, Research, and Development, House Committee on Science and Astronautics, Rayburn House Office Building, Washington, D.C.

DEAR CONGRESSMAN DADDARIO: I am on the Board of Directors of the Social Science Research Council, and I am therefore very interested in your committee's review of the National Science Foundation. It happens that I just received a 3-year grant from that agency for a study of American urban history.

I would like you to know that I regard the NSF program as the most significant source of support for the advancement of social science research. It has initiated the best work in the field, and the work done under its auspices is of very high quality. I urge you to take account of these important facts in your deliberations.

With best wishes for a successful inquiry, I remain,

Sincerely,

LEO F. SCHNORE,
Professor of Sociology.

UNIVERSITY OF ROCHESTER,

SCHOOL OF MEDICINE AND DENTISTRY,
Rochester, N.Y., August 2, 1965.

Hon. E. Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development, House of Representatives, Washington, D.C.

DEAR MR. DADDARIO: I have read with considerable interest the statement of Dr. Alvin M. Weinberg before your committee on July 8 on "the future role of the National Science Foundation." I am a member of the community of biological sciences in this country, and also a member of the Divisional Com-

mittee for Biological and Medical Sciences of the National Science Foundation. I was particularly concerned with one aspect of Dr. Weinberg's statement, and that is his recommendation that all of the Government support for the biological sciences be placed under the National Institutes of Health. This would mean that the National Science Foundation would become an agency solely concerned with the physical sciences. I would like to vigorously counter this viewpoint by saying that I think it would be most unfortunate to remove any support for the biological and medical sciences from the National Science Foundation as it is now constituted. I think it is a healthy thing to have diversity of support for scientific research within the Government. Secondly, the uniqueness of the support for biology in the National Science Foundation derives from the fact that it covers all branches of the biological sciences, not just those related to health as in the case of the National Institutes of Health. The National Institutes of Health is already a rather monolithic structure, and I feel that it would be a mistake to increase this by giving it responsibility for all biological sciences' support. I sincerely hope that Dr. Weinberg's ideas will not be adopted and that the division of medicine in the biological sciences will not only remain in the National Science Foundation but will be strengthened.

Sincerely yours,

WILLIAM D. LOTSPEICH, M.D., *Chairman.*

UNIVERSITY OF ROCHESTER,

DEPARTMENT OF ECONOMICS,
Berkeley, Calif., August 5, 1965.

Congressman JEFFERY COHELAN,
House of Representatives,
Washington, D.C.

DEAR JEFF: It has come to my attention that the Subcommittee on Science, Research, and Development of the House Committee on Science and Astronautics is now undertaking a review of the National Science Foundation. I am very much interested in the development of NSF, and especially in the role which the

social sciences (in my case, particularly economics) have played in the work of the Foundation.

I think there is growing recognition in government, among physical scientists, and certainly within NSF, that research and training in the social sciences thoroughly deserve governmental support, and that the moderate investment that NSF has thus far made in the social sciences has been well spent.

To the extent that it is convenient for you to bring these sentiments to the attention of members of the subcommittee (I believe Representative Daddario is chairman), I should be very grateful. I am enclosing an additional copy of this letter if you would care to transmit it to him * * *.

Cordially,

R. A. GORDON,
Chairman, Graduate Committee, Professor of Economics.

UNIVERSITY OF MINNESOTA,
OFFICE OF THE DEAN,
Minneapolis, Minn., August 5, 1965.

Hon. JOSEPH KARTH,
House of Representatives,
Washington, D.C.

DEAR CONGRESSMAN KARTH: It has just come to my attention that, during the hearings of the Subcommittee on Science, Research, and Development of the House Committee on Science and Astronautics, there has been direct consideration and considerable friendly concern about the social sciences.

Under the circumstances, I cannot resist writing you with a couple of observations. First, I have been very much pleased by the increasing entry of the National Science Foundation into the support of the social sciences. I think it is fair to say that my colleagues on every side of the university would agree to the importance of support of scientific study of the economic, social, geographical, and historical dimensions of man's activities. Second, I have been most impressed and gratified by the manner in which the National Science Foundation has supported scientific study of locational patterns of resources and human settlements, as well as institutes for the upgrading of researchers and of college and school teachers, in my own field of geography.

Although the word may not reach you very often, you should know that these efforts are appreciated and are being used to the utmost of their ability by the scientists and the disciplines concerned.

Best personal regards.

Sincerely,

JOHN R. BORCHERT,
Associate Dean and Professor of Geography.

UNIVERSITY OF PENNSYLVANIA,
WHARTON SCHOOL OF FINANCE AND COMMERCE,
Philadelphia, Pa., August 13, 1965.

Congressman EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development, Committee on Science and Astronautics, Rayburn House Office Building, Washington, D.C.

DEAR CONGRESSSMAN DADDARIO: I was pleased and encouraged to learn of the interest your subcommittee has recently shown in the social sciences. During the past 2 years, I have had the opportunity to serve as consultant to the National Science Foundation, on the Advisory Panel for Economics. I was greatly impressed by the high quality, integrity, and dedication of the staff members with whom I came in contact.

All around us are urgent social problems—international political conflict, racial strife, poverty, unemployment—requiring, in the interest of our own self-preservation, objective and scientific analysis. Yet the resources so far devoted to such work seem to me discouragingly small in relation to the need. Anything your committee may do to further social science study and research would, I believe, be of the utmost value.

Sincerely,

RICHARD A. EASTERLIN, *Professor of Economics.*

YALE UNIVERSITY,
New Haven, Conn., August 18, 1965.

Hon. EMILIO Q. DADDARIO,
House of Representatives,
Washington, D.C.

DEAR MR. DADDARIO: On July 8, 1965, Dr. Alvin M. Weinberg presented to your Subcommittee on Science, Research, and Development a statement entitled "The Future Role of NSF." This statement has been circulated and I would like to comment upon certain of the points made by Dr. Weinberg.

As a biologist who has conducted research with the aid of both NSF and NIH grants and as a member of one of the NSF advisory panels, I have had opportunities to observe and to participate in various aspects of the support of university-based biology by the Federal granting agencies.

With most of Dr. Weinberg's comments I am in complete and hearty agreement. The future will be the age of biology in large part because the physical scientists have been so impressively successful in the solution of their problems, many of which are vitally pertinent to biology. All biologists will agree with Dr. Weinberg that support for the physical sciences must continue and that the support of medical research should be greatly increased.

There is really only one point at which I depart from agreement with Dr. Weinberg's highly competent analysis. That concerns the linking of biology and medicine and the suggestion that all, or most, biological research should be supported through NIH. The difficulty is simply that, as Dr. Weinberg points out, NIH is a "mission oriented" agency and not all, or even most, of biology is so oriented. Biology and medicine are, of course, intimately related but they are not complete synonyms and "biomedical" is not the same thing as "biological." If all support for biology were to be through NIH the result could easily be the exclusion from support of much of the basic biology now receiving at least modest support through NSF. I do not believe that Dr. Weinberg intends that this should occur and he does note that NSF should retain some responsibility for sciences other than the physical sciences, "especially in the universities." Perhaps this answers my question but I am still wary of the linking of a major part of basic biology to a mission-oriented agency.

The danger I see in the adoption of Dr. Weinberg's suggestion is not in the idea itself but in the easily predictable way in which it would be carried out by a mission-oriented agency. Because of the pressures which are brought to bear on such agencies (and not only by congressional committees) there is an understandable tendency to support only those projects which have direct "practical" value easily understood by everyone. As some Congressman recently said, "Don't tell me about hybrid corn again"—so I'm not going to offer any hackneyed arguments about "basic" versus "applied" research. I do hope however that it will be kept in mind that there is a great deal of biology that is not necessarily or directly related to medicine, agriculture, or other obviously applied areas but which is still deserving of support.

The National Science Foundation could undoubtedly be improved but it is highly doubtful that taking away most of its responsibility for the support of the biological sciences will improve either the NSF or biology.

Respectfully yours,

CHARLES G. SIBLEY,
Professor of Biology and Curator of Vertebrate Zoology.

NATIONAL ACADEMY OF ENGINEERING,
OFFICE OF THE PRESIDENT,
Washington, D.C., August 18, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development,
Committee on Science and Astronautics,
Rayburn House Office Building, Washington, D.C.

DEAR REPRESENTATIVE DADDARIO: Since testifying before your committee on July 15, I have received certain data regarding engineering fellowships from Dr. Leland J. Haworth, in a letter which he wrote me on August 6, a copy of which was sent to your committee. In my testimony I stated that the engineering profession felt that there was a "woeful lack of national science fellowships in engineering." Dr. Haworth's letter shows that this may not be justified, and is not consistent with the facts pertaining to the relative number of awards

in engineering and various branches of science over the years. His letter further shows that performace has been particularly favorable to engineering in fiscal 1965.

In my testimony I mentioned the subject of education in passing, as it were, and specifically suggested that facts pertaining thereto should come from those in the educational world. This letter is being written to put that part of my testimony in the proper context.

May I again express my appreciation of the constructive spirit with which you are handling these hearings.

Respectfully,

AUGUSTUS B. KINZEL.

UNIVERSITY OF CHICAGO,
DEPARTMENT OF GEOGRAPHY,
Chicago, Ill., August 18, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development, Committee on Science and Astronautics, Rayburn House Office Building, Washington, D.C.

DEAR MR. DADDARIO: In connection with your review of the National Science Foundation you may have some interest in foreign governmental provision for support of sciences. My own information is limited to geography and some of the other social sciences, but I have noticed the following general features:

(1) All the foreign equivalents of our National Science Foundation make provision for including the whole range of the sciences—physical, biological, and social—though in varying propositions.

(2) The method of support varies between two general patterns:

(*a*) in Eastern European countries, in general, the academies of science or research supporting organization tend to establish independent research units separate from universities but part of the academies of science themselves. This is true, for example, of the Akademiia Nauk in the U.S.S.R., the Ceskoslovenská Akademie Věd and the Slovenská Akadémia Vied in Czechoslovakia, of the Magyr Tudományos Akadémia in Hungary, of the Academia Republicii Populare Romíne in Rumania, and of the Bŭlgarska Akademija na Naukite in Bulgaria, but only partly the case with the Polska Akademia Nauk in Poland. What is characteristic of each of these mechanisms for national governmental support of science of all types is the rapid rise in level of support as a basic feature of national policy, which considers such expenditures as productive investments which will pay high dividends in the advancement of the economy and society of these countries.

(*b*) in Western and southern European countries the typical pattern is a science foundation or academy which makes grants to existing institutions (mostly universities or institutes in universities). This tends to be true for example of the Deutsche Forschung gemeinschaft in the German Federal Republic, or of the Centre National de la Recherce Scientifique in France, or the Consiglio Nazionale delle Ricerche in Italy, or the Consejo Superior de Investigaciones Cientificas in Spain.

I have been struck by the high quality and importance of work supported by our own National Science Foundation in recent years.

Yours sincerely,

CHAUNCY D. HARRIS, *Professor of Geography.*

HARVARD UNIVERSITY,
CENTER FOR INTERNATIONAL AFFAIRS,
Cambridge, Mass., August 20, 1965.

Congressman EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development,
House of Representatives, Washington, D.C.

DEAR MR. DADDARIO: I have heard from Dr. Pendleton Herring, the president of the Social Science Research Council, of the sympathetic interest in the social sciences manifested by you and the members of the Subcommittee on Science, Research, and Development during recent hearings in Washington on the legislation concerning the National Science Foundation. The reception given to the social sciences in Washington is not always friendly, indeed it is often hostile, and, more serious, based on profound misunderstanding of their organization, values, and purposes. This makes it particularly refreshing and promising to

learn that in your subcommittee a more enlightened attitude apparently prevails.

As one who for many years served as a social science analyst in Washington, and since then worked intimately with defense agencies, the Department of State, and the welfare agencies of the Government in various social science projects, I can testify that social science has a vital role to play in the affairs of our Government. More basic, I believe that it has a crucial place in the pattern of American life. The great sociologist Durkheim said long ago that only a truly free society could tolerate and would support the social sciences. The way in which those disciplines flourish in the United States, and either languish or even are forbidden in Soviet Russia and Communist China, lends support to this dictum. Without in any sense wishing to put myself in the position of a special pleader for the interests of my own field, I do hope that in the legislation on the NSF you will find a way to give the social sciences their proper and just place among the sciences which man honors because they honor him.

Sincerely yours,

ALEX INKELES,
Professor of Sociology.

PENNSYLVANIA STATE UNIVERSITY,
OFFICE OF THE PRESIDENT,
University Park, Pa., August 24, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development,
House of Representatives, Washington, D.C.

DEAR CONGRESSMAN DADDARIO: I am writing to you at the suggestion of Mr. George A. Whittington, editor of Research and Development magazine. Mr. Whittington heard a presentation of our report on "Continuing Professional Educational Needs of Engineers" at an R.&D. seminar at our university and urged that I communicate this information for consideration by your Subcommittee on Science, Research, and Development.

The Methods Research Division, Continuing Education, the Pennsylvania State University, has just completed a study on the updating needs of 2,090 engineers who have been working in industry for at least 5 years.

The study provides comprehensive, quantitative data on the updating needs of engineers in the basic sciences, engineering sciences, the applied aspects of engineering, management areas, and the social science and humanities educational needs.

To reduce the problem of obsolescence, it is urgent that engineers and scientists be kept abreast of newly developed information. Our study provides evidence of the importance of the problem and the critical need to intensify the development of policies to meet these technological needs.

Enclosed is a copy of "Highlights," a brief summary of the study, and a copy of the research report. Should your committee require additional data from the other reports stemming from our project, we will be glad to furnish them to you.

If I can be of further assistance to you, please do not hesitate to write me.

Sincerely yours,

ERIC A. WALKER, *President.*

[From "Highlights," Pennsylvania State University, Continuing Education]

A SURVEY OF CONTINUING PROFESSIONAL EDUCATION FOR ENGINEERS IN PENNSYLVANIA

(By Samuel S. Dubin, Ph. D., LeRoy Marlow, D. Ed.)

PREFACE

Few issues of current technical publications appear without some reference to the exponential growth of knowledge and the obsolescence of engineers. Much talk, many words, and some individual case studies are on record, but there has been a dearth of factual information.

The Pennsylvania State University desired to assess the extent and magnitude of the problem before formulating plans to meet these needs. The "Survey of Continuing Professional Education for Engineers in Pennsylvania" was limited to the self-determined needs of engineers employed in various positions in Pennsylvania.

A sample of 2,090 practicing engineers was carefully selected so as to be representative of the number of engineers in Pennsylvania in each industrial category, covering companies of all sizes and including engineers at various levels of responsibility and of all age groups, but excluding those who had received their B.S. degrees within the preceding 5 years. For the first time, to my knowledge, statisticaly signficant data are available from which to draw conclusions.

Action to meet these now-determined professional needs in the Commonwealth is of paramount importance. Areas of great need have been indicated as a result of actual survey rather than a conclusion masterminded by either the local demands of industry or the surmise of the academics.

It seems clear that practicing engineers themselves recognize the need for further study. Respondents indicate that they would take further work, if available, not only in technical but also in managerial and social-humanistic studies for improvement of both their professional skills and general education.

Imparting knowledge is by no means an exclusive prerogative of universities. Practicing engineers can learn from many sources and many experiences, but educational institutions have traditionally been looked to as sources of additional knowledge. Presumably, we in the universities and colleges not only know how to teach but also recognize and can enforce the rigorous and high standards needed to insure that time spent in study will be worthwhile. Financial means must be found to prepare and to offer up-to-date instruction in the selected fields where the demand is widespread if we are to make the best use of our professional personnel in the technological and managerial areas.

HIGHLIGHTS OF SURVEY RESULTS

This report is a condensation of the survey "Continuing Professional Education for Engineers in Pennsylvania" and includes the objectives, scope, and methods used; a justification of the project; highlights of the results; and the recommendations.

Objectives of the survey

1. To determine the self-perceived educational needs for engineers who have been out of college 5 or more year.
2. To determine attitudes of engineers toward continuing education needs as related to their job, supervision, and company.
3. To recommend methods for providing continuing education programs to update engineers.

Scope of the survey

Two methods were used:

1. A written questionnaire was completed by 2,090 engineers in 171 industrial and 4 governmental organizations. It was composed of four parts: General information, professional education, management education, and social science and humanities.
2. Group interviews were conducted in 51 companies; 408 engineers participated in 123 interviews. The interviews involved engineers who supervise technical operations, direct management activities, and perform technical duties.

Justification for the survey

The conditions which stimulated the undertaking of this survey are—

1. Engineering knowledge and techniques have a rapid technological obsolescence.
2. The growth rate of knowledge is accelerating rapidly.
3. The demand for professionally trained engineers will persist for many years.
4. Strong personal motivation is required for an engineer to remain up to date.
5. The growth rate in research and development programs and expenditures requires constant altertness to current developments in engineering.
6. Industrial processes and products continue to become increasingly complex.

ADDITIONAL REPORTS

The findings from this research project are available in three forms:

1. The "Survey Report" which presents the total findings of the questionnaire and interviews in a condensed form. This report is designed for the lay reader and does not include the research design, procedures, or methodology.

2. A complete "Research Report" which includes all of the information in the "Survey Report" but in greater depth plus an expanded discussion of the background, significance, and methodology of the study.

3. Fifty-three "Engineering Education Research Reports" which present data pertinent to industrial groups, major fields of engineering, State geographical locations, registered professional engineers, time in profession, course needs, and related information. Titles listed below:

NONCREDIT COURSES

E 52	A Tabulation of Noncredit Courses

Engineers reported an interest in the following:

	Percent[1] expressing a need for
1. Technical skills:	
Basic Sciences:	
Probability and statistics	62
Review of college mathematics	53
Review of college physics	48
Calculus	47
Modern algebra	46
Differential equations	43
Modern analysis	43
Modern algebra	43
Statistical inference	42
Engineering sciences:	
Engineering economy	68
Engineering analysis	61
Computer programing, digital	57
Engineering materials metals	55
Computer programing, analog	53
Information data processing	51
Electronics	47
1. Technical skills—Con.	
Engineering sciences—Con.	
Heat transfer	47
Construction materials	45
Engineering materials, plastics	43
Fluid mechanics	42
Stress analysis	41
Corrosion-electrometallurgy	40
Metallurgy	40
Engineering analysis, design and systems:	
Automation	54
Program evaluation and review techniques (PERT)	48
Instrumentation, measurement, and process control	47
Work simplification and measurement	47

See footnote 1, p. 1461.

	Percent[1] expressing a need for
1. Technical skills—Con.	
Engineering analysis, etc.—Con.	
Production management	46
Quality control	43
Systems engineering	41
2. Communication skills:	
Rapid reading	80
Effective communication in organizations	78
Conference leadership	77
Public speaking	76
Oral presentation of statistical and technical reports	74
Technical report writing	74
Business letter writing	70
Listening skills	67
Composition and rhetoric	57
Interviewing skills	53
Engineering graphics	42
3. Managerial skills:	
Job evaluation	68
Human relations skills	61
Business law	57
Man-machine interface (human engineering)	55
Product planning	54
Analyzing organizational effectiveness	53
Budgeting and auditing	51
Understanding individual and group behavior in work situations	47
Supervisory training, employee development	47
Decisionmaking training by use of simulation methods	45
Performance appraisal, coaching techniques	43

	Percent[1] expressing a need for
3. Managerial skills—Con.	
Selection and assessment of personnel	42
Value analysis	41
Information data processing systems for decisionmaking	40
Financial planning and forecasting	40
4. Social sciences and humanities:	
Work related needs:	
Economics	63
Logic	61
English composition	58
Ethics	57
Psychology	53
Community and public relations	50
Leisure time needs:	
Community and public relations	68
Fine arts—music	65
Logic	63
Psychology	62
Literature	61
Religion	61
International understanding	58
Philosophy	58
Economics	55
Ethics	53
Fine arts—theater	52
Political institutions	52
Sociology	48
History	47
Fine arts—art	46
International economics	46
English composition	44
Foreign languages	44
Fine arts—painting	40

[1] Percentages include compined responses of the first two choices from a three-point scale: "Should Have," "Could Use," and "Don't Really Need." Items scoring below 40 percent are not listed. Percentages express degree of need for those answering each item.

5. Postcollegiate degree work:
   6 engineers (0.3 percent of 2,090 engineers) were working on an additional B.S. degree.
   93 engineers (4.4 percent of 2,090 engineers) were working towards a masters degree.
   12 engineers (0.6 percent of 2,090 engineers) were working toward a doctorate.
   Only 4 percent reported that postcollegiate work was required for promotion or salary increase.
   Most frequent reasons for not seeking degree:
   1. Do not have time.
   2. Too far from educational center.
   3. Job does not demand more education.
6. Nondegree work:
   1,183 (58 percent) wanted to enroll in noncredit courses if offered locally.
   1,106 (55 percent) wanted to enroll in advanced credit courses if given locally.

7. Updating methods:

The following sources were used frequently for updating:	Percent using
Scientific-technical journals	50
Manufacturer's literature	35
Technical books and reports	28
Company-industry policies and procedures	29
Business reports	15
Professional society meetings	13

726 (35 percent) of the engineers surveyed participated in no educational activity during the past 4 years.

University day courses were "used frequently" by less than 1 percent (N=15) and university night courses by 6 percent (N=107).

8. Methods preferred for updating (other than formal classroom):	Percent expressing a preference
Correspondence courses	35
Educational television	34
Programed instruction	31

9. Functions and activities:

The most frequently ranked functions and activities were:

Function	Rank [1]	Mean percent of time spent [2]
Administration	1	25
Design	2	24
Development	3	20
Activity		
Conferences	1	7
Correspondence	2	8
Planning and organization	3	13
Supervision	4	22

[1] By frequency of participation.
[2] Rank and mean percent of time spent are independent calculations.

10. Professional development:

1,433 (72 percent) indicated that their company permits in-service training courses to be held on company time.

1,384 (67 percent) believed their company encourages them to enroll for advanced work but 1,683 (81 percent) believed post-collegiate work is not required for promotion or salary increase. An additional 315 (15 percent) did not know whether or not such work is required.

11. Supervisors' attitude toward further education and training: 1,313 (64 percent) reported that their supervisors take a noncommittal attitude to their further education or training.

12. Educational assistance plans:

1,624 (79 percent) of the engineers reported that their companies have an educational assistance program.

1,493 (74 percent) indicated that the availability of a company-paid educational assistance program had no effect on motivating them to undertake educational work.

13. Professional engineering registration:

551 (27 percent) were registered professional engineers.

761 (43 percent) wanted to take a course to prepare them for the professional engineer examination.

585 (33 percent) desired to take the professional engineer examination.

14. Associate degrees: The programs most needed by companies in the opinion of engineers were:

	Combined percent of "would like to have" and "anticipate need" [1]
Computer technology	80
Instrumentation and control technology	78
General engineering technology	74
Electrical and electronic technology	72
Production technology	62
Drafting and design technology	60
Maintenance technology	56

[1] First 2 choices of a 3-point scale.

15. Year of B.S. degree: 1,573 (75 percent) received their B.S. degree between 1949 and 1959.
16. The shift from undergraduate fields of engineering to present work:
Comparison of ranks between undergraduate degree in specific field of engineering with present engineering work shows considerable shifting.
This mobility indicates need for continuing education.
17. Education need and size of company: No relationship was found between size of company and educational need. The updating needs of engineers were similar for all sizes of companies except on selected items. These exceptional differences existed only in the very large companies.

RECOMMENDATIONS

For the university

1. The university should assume a leadership role and greater responsibility in meeting the continuing profesional educational needs of engineers as determined by this study. This recommendation can be implemented by—

(*c*) A greatly expanded educational program in all phases of computer sci- mathematics (probability and statistics, calculus, modern algebra, review of college mathematics); physics (review of college physics and solid state physics); and chemistry (review of college chemistry).

(*b*) Additional courses of instruction in the engineering sciences, especially in subject matter where high demand has been demonstrated in this study; e.g., electronics, engineering analysis, engineering economy, engineering materials, and heat transfer.

(*c*) A greatly expanded educational program in all phases of computer sciences and their scientific and engineering applications to business and industry.

(*d*) Additional courses of instruction in the subject matter of engineering analysis, design, and systems, where a high degree of need has been shown, such as automation; instrumentation, measurement, and process control; systems engineering; and program evaluation and review techniques.

(*e*) A larger program in communications specifically for practicing professional poeple with emphasis on such topics as improved reading techniques, conference leadership, technical writing, and oral presentation of statistical and technical information.

(*f*) More extensive offerings in general management, personnel management, and financial management to meet the needs of the engineer whose main responsibilities have become administrative and managerial.

(*g*) Added offerings in those social sciences and humanities which relate to the work of the practicing engineer, such as economics, logic, English composition, ethics, psychology, community relations, technology and economics, technology and human values, and humanities in a technological society.

2. Seminars, workshops, and other informal types of noncredit instruction should be increased to meet the demand for advanced education not directed to the goal of a higher degree.

3. Continuing professional education programs should be expanded and offered at convenient times and in as many locations as possible. These offerings should utilize schools, colleges, and other facilities suitable for instructional purposes and be located within commuting distances of as many engineers as possible.

4. Associate degree programs should be expanded to meet the requirements of industry for technicians in such fields as computer, instrumentation and control, and general engineering technologies.

5. New techniques of learning should be explored to facilitate the updating of practicing engineers. Suggested methods are correspondence study and in-plant courses plus periodic campus study, radio and telephone lectures, tape recordings, and educational television. A special inquiry should be made into the use of self-study and tutorial methods.

6. Engineering faculty must imbue the undergraduate with the importance of keeping abreast of new developments after graduation, and with the need for continuing self-instruction and lifetime learning.

7. Evaluation programs must be devised and conducted to demonstrate the extent to which participation in continuing education programs improves the engineer's effectiveness on his job.

For the company

1. Management, to be creative, should initiate and foster the updating of its employees. This process requires a three-pronged attack: (1) Personal motivation of the individual employee; (2) the strong support and encouragement of supervisory personnel; and (3) company policy which insists on updating its personnel as a part of the daily work.
2. More released time should be granted engineers to take advanced degrees and noncredit work. For this purpose, sabbatical leave should be provided as a regular practice.
3. Long-range educational programs should be initiated and financed to parallel long-range company programs and policies.
4. Top management should review periodically the updating needs of its practicing engineers and initiate corrective action where necessary.

For the professional society

1. Professional societies, in conjunction with universities, should seek to motivate engineers to pursue continuing professional education.
2. Engineers should be encouraged to become active in their professional societies in order to keep abreast of current technical developments as reported in the literature and professional meetings.
3. Professional societies should expand their offerings of short-term courses, utilizing, where feasible, varied media of instruction to fulfill the needs of practicing engineers.

For the State government

1. Policies of the State government should foster updating by—
   (*a*) Periodic reviews of updating needs of its practicing engineers and initiating corrective action where necessary.
   (*b*) Providing educational assistance for employees who undertake continuing professional education to keep abreast of current developments in their fields.
   (*c*) Initiating and financing long-range educational programs to parallel long-range programs and policies.
   (*d*) Granting released time to engineers to take advanced degrees and noncredit work. Sabbatical leave should be provided on a systematic basis.

For the engineer

1. The engineer has a responsibility to himself and to his company to undertake continuing professional education to keep abreast of current developments in his field.

MUSEUM OF COMPARATIVE ZOOLOGY,
HARVARD UNIVERSITY,
Cambridge, Mass., August 27, 1965.

HON. EMILIO DADDARIO,
House of Representatives,
Washington, D.C.

DEAR CONGRESSMAN DADDARIO: I recently had an opportunity to read a statement by Dr. Alvin M. Weinberg on the future role of NSF, which was to have been presented before your subcommittee on July 8, 1965. There is a great deal of sound commonsense in this statement and I wholeheartedly agree with Dr. Weinberg's imperative: "Make the coming age the 'age of biology.'"

Dr. Weinberg speaks as a physicist and looks at certain matters from his parochial viewpoint. He seems to think that all of biology is health related and that the National Institutes of Health should and could take care of biology. He implies that most of biology ought to be transferred to NIH and that NSF become primarily, though not exclusively, an agency dealing with the support of the physical sciences.

I shall not discuss, in detail, support for the physical sciences but want to point out that most of the $1½ billion estimated to go for basic research in DOD, AEC, NASA, for 1965 will go to research in the physical sciences. To denote the National Science Foundation to the limited role of serving as an agency for the physical sciences would greatly weaken biology and achieve precisely the opposite of what Dr. Weinberg said should be achieved in future years; namely, a strengthening of biological research.

There are vast areas of biology, particularly those dealing with whole organisms and with populations that are not "health related." When Dr. Weinberg says: "I visualize NIH greatly expanding its role as a National Science Foundation for the basic biological sciences," he overlooks the fact that ultimately NIH is basically devoted to applied science. Only in this case it is applied to health problems, while in DOD physical science is applied to defense problems and in the AEC it is physical science applied to problems of atomic energy.

The precise argument which Dr. Weinberg uses, that the physical sciences "being the handmaidens of [applied] agencies * * * can hardly expand," is true for biology if entirely attached to an applied, health-related institute."

Biology is far bigger than its health-related aspects and would suffer cruelly if turned into a "handmaiden" of an agency specifically constituted to be essentially applied (health directed). I am not, in the least, questioning some of the superb basic research going on in NIH, but its scope is clearly limited. Vast areas of biology have not received any attention by NIH, and should not if NIH wants to live up to its constitution. This includes most of environmental biology, population biology, evolutionary biology, invertebrate paleontology, much of phychobiology, much of genetics, and marine biology, to mention a few areas that have just come to my mind (without any attempt at completing this list).

It is of the utmost importance that basic biological science not only remain in NSF, but that it be greatly strengthened. Biological research is far more apt to produce results which run counter to our cherished beliefs and prejudices than is physical science. To maintain the independence and dignity of biological science it is important that it continues to receive support from an independent agency, which is specifically charged to promote basic research, rather than an applied agency.

Dr. Weinberg points out correctly that many of the most "crucial public problems that are now emerging, need entirely new approaches." Although they "do not obviously fall directly in the physical sciences," he hopefully expresses the wish that physical scientists might be of use "as people well grounded in the discipline of the exact physical sciences transfer into more complex, more difficult, social sciences." This is surely true. Yet, operational research in the last war had shown surprising, that naturalists, who are used to operating with numerous unknown variables, were often superior to physical scientists in the study of complex systems. Naturalists are among the kinds of biologists who would find it difficult to get support from a purely health related agency.

To sum up, it would seem to me that nothing would weaken biology as much as a transfer of the non-health-related areas of biology from NSF to NIH.

Indeed, the very arguments which Dr. Weinberg uses in favor of strengthening the physical sciences in NSF militate even more strongly in favor of a drastic expansion of the biological sciences in the National Science Foundation.

I say with Weinberg: "Make the coming age the age of biology" by strengthening not only applied, but also basic biology. That objective, however, can be achieved properly only within the National Science Foundation, with its uncommitted interest in basic research in all branches of biology.

Sincerely yours,

ERNST MAYR,
Member, National Academy of Sciences.

UNIVERSITY OF PITTSBURGH,
DEPARTMENT OF HISTORY,
Pittsburgh, Pa., August 31, 1965.

Hon. WILLIAM MOORHEAD,
House Office Building,
Washington, D.C.

DEAR BILL: I understand that the Subcommittee on Science, Research, and Development of the House Committee on Science and Astronautics is currently undertaking the first legislative review of the National Science Foundation since it was established. I have spoken to you in the past in appreciation of your efforts in behalf of a National Humanities Foundation, and am extremely pleased with the progress this effort has made. But I wanted to write you as well about the relationship of the social sciences to the National Science Foundation.

As you know, historians have many diverse interests and while some have very close ties to the humanities, others have equally strong interests in the social sciences. This is especially true of such fields as economic, political and

social history. We have, therefore, been especially interested in the development of the National Science Foundation's interest in the social sciences and have hoped that this interest would grow so that the Foundation could play as significant a role in the progress of the social sciences as it has in the natural sciences.

I understand that the current review of the National Science Foundation's activities includes its potential in this field. I know that you are not a member of the subcommittee, but I thought that because of your strong interest in the academic community you might wish to know of our interest in the social science activities of the National Science Foundation.

With best wishes,

SAMUEL P. HAYS,
Chairman, Department of History.

REED COLLEGE,
OFFICE OF THE PRESIDENT,
Portland, Oreg., September 2, 1965.

Representative EMILIO Q. DADDARIO,
Longworth Office Building,
Washington, D.C.

DEAR REPRESENTATIVE DADDARIO: During the last week of your subcommittee hearings, I corresponded with Mr. Philip Yeager regarding the suggestions of Dr. Arthur Scott for improvement in undergraduate education in the sciences, particularly chemistry. We sent a memorandum by Dr. Scott for inclusion in the record of your hearings.

Reprints of the relevant articles authored by Dr. Scott are now available. I thought you might appreciate a copy, which I have enclosed.[1]

May I also express the appreciation of all people associated with Reed College for your invitation to President Sullivan to testify before your committee. We are complimented that you provided him the opportunity to discuss his views.

Sincerely,

JOHN B. TALMADGE,
Administrative Assistant.

HOUSE OF REPRESENTATIVES,
Washington, D.C., September 3, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development, Committee on Science and Astronautics, House of Representatives, Washington, D.C.

DEAR MR. CHAIRMAN: I am enclosing a copy of the letter I have received from Samuel P. Hays, chairman, Department of History, University of Pittsburgh, Pittsburgh, Pa., regarding the National Science Foundation, which I thought would be of interest to you.

With best regards,

Sincerely,

WM. S. MOORHEAD,
Member of Congress.

UNIVERSITY OF PITTSBURGH,
DIVISION OF THE SOCIAL SCIENCES,
OFFICE OF THE DEAN,
Pittsburgh, Pa., September 3, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development,
House Committee on Science and Astronautics,
Rayburn House Office Building, Washington, D.C.

DEAR CONGRESSMAN DADDARIO: I have been reminded of the testimony that your subcommittee has been receiving on the National Science Foundation, more particularly on the social sciences.

You will be aware that the social sciences tend to be left out, at least in large part, from the terms of reference of the NSF; the situation may be the same for the proposed "National Humanities Foundation." This is most unfortu-

---

[1] Articles referred to are contained in committee files.

nate. Many of the gravest and most knotty academic problems deserving Federal Government support currently must make do with low or no budgets, despite generous support for some social science themes that have come from private organizations.

It is true, of course, that many of the most important research areas in the social sciences are sensitive, and may even be considered "political." All the more reason, in an inquiring society such as ours, to encourage the rigorous application of scientific methods to their analysis and (hopefully) to their solution.

I urge you to widen the scope of NSF to include the social sciences.

My very best wishes.

Sincerely,

RICHARD L. PARK, *Dean.*

UNIVERSITY OF CHICAGO,
DEPARTMENT OF ANTHROPOLOGY,
Chicago, Ill., September 7, 1965.

Hon. EMILIO DADDARIO,
Subcommittee on Science, Research, and Development,
House of Representatives,
Washington, D.C.

DEAR MR. DADDARIO: I have just been apprised of the fine work of your committee in the general field of science and in your interest in the development of the social sciences. As you might expect, my colleagues and I are immensely interested in the work of your committee, and would be eager to receive any information from you concerning your plans, and would be happy to assist you with any advice we might be able to offer.

Wishing you every success in your important venture, I am,

Sincerely yours,

MELFORD E. SPIRO,
Professor of Anthropology.

ECONOMETRICA,[1]
September 9, 1965.

Hon. EMILIO Q. DADDARIO,
House Office Building,
Washington, D.C.

DEAR CONGRESSMAN DADDARIO: I understand that your Subcommittee on Science, Research, and Development has been conducting hearings on the work of the National Science Foundation.

As an editor of one of the economics journals dealing with some of the more technical aspects of the field, I see a large number of research reports from scholars all over the country. A number of these indicate that the work has been supported by grants from the National Science Foundation. My impression is that in this way the Foundation has been responsible for important financial assistance given to this branch of the social sciences. This is support that is very much needed, not only in economics but in the other social sciences as well, and I am writing to urge the continuation and expansion of the social science programs of the National Science Foundation, in view of the accomplishments to date.

I have also served during the past 3 years as a consultant to the National Science Foundation on its equipment grants program in the social sciences. In that capacity I have seen some very noteworthy proposals. The Foundation has been able to give some important help in these cases, though only on a limited basis because of its own limitation of funds. I believe that this program has also been demonstrably worthwhile and that the availability of more funds for it would, in terms of accomplishments, prove to be very worth while from a national point of view.

I do not wish in any way to understate the achievements of the National Science Foundation in developing the study of our social institutions. These achievements have been great, and I hope that the program will be continued and expanded because there is much paydirt that remains to be tapped.

Sincerely yours,

ROBERT H. STROTZ, *Managing Editor.*

UNIVERSITY OF MICHIGAN,
DEPARTMENT OF SOCIOLOGY,
Ann Arbor, Mich., September 10, 1965.

Dr. WESTON VIVIAN,
House Office Building,
Washington, D.C.

DEAR WESTON: I have been reading with great interest reports of the hearings by the Subcommittee on Science, Research, and Development. Scientists, and especially the social scientists, form only a minute part of your constituency, but I thought you might like to know that at least one social scientist is impressed by the care and foresight shown in reports of your subcommittee's work. I wanted also to reinforce what I have seen of testimony before the subcommittee, namely the thesis that wise planning does not now require the allocation of vast new funds to support social science. We need, as the testimony indicates, some additional funds to support students and facilities and selected, larger scale research undertakings. We also need to have a position within the National Academy of Science commensurate with our position in the National Institutes of Health and within HEW: a position in which we are recognized as full-fledged members and through which we can gain such financial and other support as we may come to need and merit.

Congratulations on a difficult job well done.

Sincerely,

GUY E. SWANSON.

DARTMOUTH COLLEGE,
DEPARTMENT OF ECONOMICS,
Hanover, N.H., September 29, 1965.

Hon. EMILIO Q. DADDARIO,
Chairman, Subcommittee on Science, Research, and Development,
House Office Building
Washington, D.C.

DEAR MR. DADDARIO: We have learned recently that your subcommittee is reviewing the scope of the National Science Foundation's activities and that lately the subcommittee has shown some positive interest in the relationship of the National Science Foundation to the several social sciences. We urge that your subcommittee recommend an intensification and broadening of Federal financial support of the social sciences and, especially, of the various fields of economics with either the National Science Foundation or a new and correspondingly specialized foundation for the social sciences as the instrument for administering the support. We feel strongly that the advancement of our Nation on many critical fronts is closely dependent on continuing advancements in social science research and that substantial Federal support of this research is not only justifiable but also urgently necessary.

Respectfully yours,

M. O. Clement, J. A. Menge, Robert M. Dent, Jan A. Stewart, Frederick J. Glover, Gary McDervell, Tom Elle, Gerald L. Childs, Martin L. Lindahl, Laurence Hines, Daniel Compton, Richard L. Pfister, William H. Wrean, David A. Belsky, William L. Baldwin, Harvey Galper, Colin D. Campbell, Clyde E. Dankert, Members of Department.

NATIONAL SCIENCE FOUNDATION,
NATIONAL SCIENCE BOARD,
Washington, D.C., October 4, 1965.

Hon. EMILIO Q. DADDARIO,
Rayburn House Office Building,
Washington, D.C.

DEAR MR. DADDARIO: It has been some time since several of us who are members of the National Science Board took opportunity to write to you with respect to the various questions which you raised during the summer hearings concerning the National Science Foundation.

I have given much thought to these matters in the interim, particularly with respect to the role of the Board.

My crystal ball is not clear enough to project the longtime position which should be established. I do know that the current position, de jure, is simply not practicable. The Board is responsible, in the law, not only for the generation of policy but for the operations of the Foundation. The question which has been raised is whether or not that relationship should be changed to one which is purely advisory. Much can be said on behalf of such a suggestion in which I have previously concurred. It would seem to be realistic, it would recognize that the Congress is the true board of trustees of this Foundation. and it would free the Board to serve as critic of the Foundation staff were such a position ever desirable. Let me say at once that at this moment in time, quite the contrary is the case. To my knowledge all of my colleagues share my admiration and respect to those in charge of the affairs of the Foundation, i.e., Dr. Haworth and his senior colleagues.

But I do not believe that the Nation will be well served at this moment by swinging the pendulum this violently. Certainly such an action would be taken amiss by the totality of the academic and scientific communities. And it would directly stand in contrast to the structure of the recently created National Foundation for the Arts and Humanities, which was clearly modeled after the NSF.

What is required, I do believe, is a transition to a new situation in which the Board retains its present position with respect to the determination and generation of policy for the Foundation but surrenders its authority with respect to operation. It is the latter aspect of its current responsibility which is impracticable and troublesome. Such a transition would be understood by all concerned and be entirely sensible at this time.

I am not at all certain whether such a transition requires legislation or whether we can continue, as presently we do, with the Board actually serving in the role of policymakers while delegating its authority increasingly to the Director with respect to operations. It seems to me this is the matter for your determination. It would result by either route, legislation or voluntary action on the part of the Board, in a clearly defined arrangement whereby the Board retains its present responsibility and authority with respect to the generation of policy, surrenders all authority with respect to operations and is available to the Director, as an advisory body, for consultation with respect to those operations.

I know that it is late to place such a letter in your hands, but if matters have not yet gone beyond some irreversible point, I hope that you will find it of interest and perhaps of some use to you.

Sincerely yours,

PHILIP HANDLER.

James B. Duke, Professor, Chairman, Department of Biochemistry, Duke University, Vice Chairman, National Science Board.

THE ASSISTANT SECRETARY OF COMMERCE,
Washington, D.C., October 4, 1965.

Hon. WESTON E. VIVIAN,
House of Representatives,
Washington, D.C.

DEAR MR. VIVIAN: I regret the delay in providing response to the question you raised during the National Science Foundation hearings concerning the use of Government research facilities by industry; however, we have been searching for any reports that might exist which are specifically directed to this question. To our knowledge, no such extensive report exists, nor have we been able to identify any systematic study of the use that is being made by industry of Government research facilities.

From my own background knowledge and experience on this matter, we have attempted to identify some specific examples of the relationships which exist between industry and Government. I should note, however, that where such relationships do exist, they are conducted with diversity and inconsistency. I would like to relate a few examples:

The Atomic Energy Commission has internship programs at a number of its national laboratories where it brings qualified people from industry, at AEC expense, to participate in research and carry back science and technology to the industrial laboratories. NASA has the beginnings of a similar program.

The National Institutes of Health do make their laboratories completely accessible to industrial visitors from the pharmaceutical and medical instruments industry, although there are apparently no NIH-sponsored industrial investigators. There is some question as to whether there are or are not industrial investigators participating in setting up some of the Environmental Health Centers of the Public Health Service.

The Department of the Interior has concluded at least two types of arrangements. In the Bureau of Mines there was a recent instance where a pilot plant scale blast furnace was made available to a consortium of steel companies, who were interested in exploring new methods for steelmaking and for utilization of scrap. Also, in the Bureau of Mines the Oil-Shale Experiment Station in Rifle, Colo., was made available for experimentation by commercial groups, including Union Oil Corp., to conduct tests on oil-shale recovery and refining. The Office of Saline Water operates some of the demonstration plants (Government-sponsored) with joint crews of OSW and industry personnel.

The Department of Defense has many laboratories, such as the Lincoln Laboratory, the Naval Research Laboratory, etc., where some degree of cooperation and use, jointly with industry, has been established. However, data are not on hand about the extent or conditions for industrial participation.

Within the National Bureau of Standards, industry is making use of facilities at least to the following extent: there are now 40 industrial research associates at NBS (there were 34 here at the beginning of 1965). These industry-sponsored research associates are in addition to our professional staff of 1,700.

You will find attached hereto a list of the laboratories of the Federal Government where there appears to be at least potential for joint cooperation with industry. I am also including a table showing the number of scientists and engineers employed in the Federal establishments, by agency, which provides further background on the potential use of research facilities by industrial groups.

I trust that this information will prove helpful to you, and please feel free to contact me if we can be of any further assistance.

Sincerely yours,

J. HERBERT HOLLOMON.

ASSOCIATION OF STATE COLLEGES AND UNIVERSITIES,
October 8, 1965.

Hon. GEORGE P. MILLER,
Chairman, Committee on Science and Astronautics,
House of Representatives,
Washington, D.C.

DEAR CONGRESSMAN MILLER: President Fred Harcleroad of the California State College at Hayward has informed me of your interest in "ASCU Studies No. 4-1965" which contains the report of the ASCU Committee on Federal Grants. We hope this information can be brought to the attention of the committee.

You are most welcome to use or reproduce any of the material contained in this report in any way you see fit.

We would appreciate having a copy of the committee report when it is available. Please let me know how we might be of further service to you.

Sincerely,

ALLAN W. OSTAR,
Executive Director.

REPORT OF COMMITTEE ON FEDERAL GRANTS [1]

(From ASCU STUDIES NO. 4, 1965)

(By John R. Emens, president, Ball State University, Muncie, Ind.)

There has been much discussion and some collection of facts concerning the participation in Federal programs by colleges and universities which are members of the Association of State Colleges & Universities. Some grants have been available to institutions of higher education for many years, but during the past few years programs and expenditures have expanded. It is increasingly difficult to keep well informed and to develop the knowledge necessary to obtain the grants desired. Your committee composed of President John King (Emporia, Kans.) and myself is endeavoring to highlight these programs by presenting here a résumé of the study conducted by Dr. David Rice, director of institutional research at Ball State University, in 1964. The more significant data are presented in a chart and table as an appendix to this report.

This study covered selected programs in the National Science Foundation and in the Office of Education. It was restricted to proposals submitted for approval during the fiscal year 1963. It was similar to an earlier study of proposals submitted in fiscal year 1962. The 1962 study brought responses from 142 members; 24 did not report. In 1963 there were 175 members. Of these, 129 responded; 46 did not.

In 1962, 58 of the institutions responding did not request participation in any of the programs surveyed. Among the 84 institutions which submitted proposals, 62 (73.8 percent) had 1 or more approved.

In 1963, 41 of the 175 respondents did not submit requests. Among the 134 which did 71 institutions (80 percent) had 1 or more proposals approved.

We selected the National Science Foundation and the Office of Education for study, believeing that their types of grants were more related to our kinds of programs. In the National Science Foundation we listed sponsored research, course content improvement, institutes of science and mathematics, undergraduate instructional equipment, and undergraduate science education. We have maintained in all of our contacts with NSF, whenever we have visited them, that we believe it is essential to improve instruction in the elementary and secondary schools through these programs, as well as in some instances to conduct research. We believe also that even in research in most instances the Congress wanted many projects related to elementary and secondary schools as well as to collegiate education. In our type of institution, in which such a large percentage of people are involved in learning how to be teachers, at the inservice or graduate level, we should expect some real consideration.

Our study of grants requested in 1963 shows that we have been recognized in some areas. In others we owe it to our selves to get our institutions busy if they really want to do a teacher education job with some help from the Federal Government.

In the entire United States in 1963 there were 5,356 requests for sharing in sponsored research. Of these, 2,709 were approved—an approval rate of approximately 50 percent. There were 87 proposals from our ASCU institutions, and 40 were granted. This means we had a 46 percent approval rate. The number of ASCU proposals was 1.6 percent of the total submitted. Our percentage approval of the total volume was 1.5 percent. The amount we received was 0.8 percent—eight-tenths of 1 percent—of the total funds appropriated. The reason for the 0.8 percent is that although ASCU members received 1.5 percent

[1] This report summarizes and analyzes the more significant findings of a study conducted in 1964 by Dr. David Rice, director of institutional research, Ball State University, Muncie, Ind. President Emens has pointed out important implications for ASCU members and has suggested next steps. The data collected by Dr. Rice were reported in detail in "ASCU Studies No. 3, 1964."

of all grants made, many of the grants we obtained were smaller than the average.

In the field of course content improvement, there were 233 requests in the whole United States, and 99 of them were approved—42 percent of the total. I do not know whether it is shocking, but it is surprising that of 177 institutions of our kind only 5 of us were sufficiently interested in course content improvement to ask the Federal Government to assist us. We obtained one grant, or 20 percent; the ASCU percentage of proposals was 2 percent of the total; approvals, 1 percent.

For science and mathematics institutes there were altogether 1,404 proposals with 929 approvals—an approval rate of 66 percent. Our institutions asked for 127 of the total 1,404. We had 82 approvals or 664 percent; 9 percent of the total number of proposals and 6.8 percent of the total number of dollars appropriated for that purpose.

For help in obtaining undergraduate instructional equipment, there were 829 requests and 523 approvals. We had only 47 institutions that "needed" (enough to request) this equipment; 66 percent of those who asked were granted some money; 4.5 percent of the dollars were allocated to ASCU institutions.

For undergraduate science education,there were 1,095 requests and 596 approved, or 54 percent approval. We submitted 23 different requests and 13 were granted, or a 56 percent approval rate; and, again, 1 percent of the money.

Of the total of those 8,917 requests submitted to NSF there were 4,856 approvals, which is a 54-percent rate. There were 289 requests from all of our institutions put together, with 167 approvals, which is an approval rate of 58 percent of those who asked. But this is only 3.5 percent of the total number of approvals because approximately 50 percent of our people did not ask.

We turn now to the Office of Education programs, and again I say the ones studied were selected; they were not the total group. In the cooperative research programs there were 600 requests altogether and 148 grants—a 24.7-percent rate. We had 31 who asked and 11 were approved or a 35 percent approval rate. You notice this is better than the national rate for this group. The grants to our members totaled 3.8 percent of the dollars.

The study showed 124 requests for National Defense Education Act guidance institutes and 76 granted. Eight of our institutions asked for these institutes and only three were approved. Our proposals were 6.9 percent of the total; of these, the ones approved represented 4 percent of the grants and 1.9 percent of the dollars.

In the program of National Defense Education Act language institutes for elementary and secondary schoolteachers there were 156 requests submitted and 83 approvals, or a 53 percent rate. We had 12 institutions that asked and 8 grants, which means we were way up in terms of the total number granted and requests made. We received 10 percent of the dollars.

The totals for these Office of Education programs were 880 requests and 307 approved, or a 35-percent approval rate; for ASCU there were 22 approvals for a 43-percent approval rate.

I do not know how significant this is, but remember there were 9,902 requests made and 5,163 grants approved; 53 percent of them were approved. We sent 340 requests and there were 189 approvals, or a 56-percent rate.

These are the programs we need to talk about. Among the new areas are the National Defense Education Act institutes, expanding into at least seven additional fields. These include the Division of Handicapped Children and Youth. Also, there is the Elementary and Secondary Act of 1965, which is supposed to appropriate again large sums of money for the improvement of elementary and secondary education. This should be of major interest to us.

These are the kinds of things we need to follow up. The concern of the committee was how we should proceed for the future. We have some facts; we have some information. We know that half of our institutions either have had a bad experience or do not have the know-how or are not interested. What should we do about these institutions? Is there some way our association can help institutions which want to have more know-how, more skill, more competence; institutions that want to find ways to participate in more of these programs and enhance their opportunities for service?

We suggest first that we might have conferences or institutes. There are two or three ways. One would be to hold regional conferences in various places on a volunteer basis.

Second, it has been suggested that we send individuals from our institutions to Washington and that Walter Hager and the group there might arrange for us to meet with different people. But I think that before we take this step it is necessary for each institution to have somebody on the campus who is going to coordinate these activities. If they just float around here and there, they get lost in the shuffle. There are various ways to accomplish this task. We at Ball State University started out in the very beginning, as I have told you, by asking a member of our faculty, which happened to be Dr. Rice, if he would devote the same amount of time to this as if he were teaching an extension class. It soon worked up to full time, and now we have employed another individual for next year. He is one of the faculty who has been in Washington working on these grants, and he is coming back to be assistant director of institutional research.

We suggest that you need such a person in your institution, and we suggest that he be from the faculty group. This individual needs to work with every faculty member. On our campus Dr. Rice works with each faculty member in any department which wants to prepare a request. He is expected to keep available for these people all types of information that comes out of Washington on the different kinds of programs, the laws and the restrictions within them, definitions, and suggestions about how you get the know-how.

You need to get a certain amount of know-how centered in one person. This person should be able to assist any faculty member in developing a program or a request. You need someone to coordinate the total program so that you will have within your institution a complete list of all requests that are somewhere between your campus and Washington or on the way back.

This brief report of your committee culminates by suggesting that:

1. Each institution in our association, if it wishes to participate in Federal grant programs, needs to have someone on the campus to coordinate the "request program."
2. ASCU might and perhaps should arrange study conferences on this subject; either regionally or in Washington.
3. We all work cooperatively with governmental agencies, foundations, and our colleagues to the end that we perform better and finer educational services.

APPENDIX 8

Representation Abroad by Atomic Energy Commission

U.S. Atomic Energy Commission,
Washington, D.C., November 16, 1965.

Dr. Edward Wenk, Jr.,
Chief, Science Policy Research Division, The Library of Congress, Washington, D.C.

Dear Dr. Wenk: In response to your letter of October 8, 1965, to Mr. John J. Burke, Office of Congressional Relations, there is attached a report providing information concerning the staffing of our foreign offices. We hope the information provided will be of benefit to you. Please let us know should additional or more detailed information be required.

As evidenced in this report, we have been able to fill our principal representative positions, as they become vacant, with well-qualified personnel from within the AEC or AEC contractor organizations. Because of the specialized nature of these overseas assignments, in their relation to the administration of U.S. Government offices and programs, incumbents must possess a well-rounded background of experience in the operating and/or coordinating phases of the U.S. atomic energy programs. Such a background is difficult to obtain to an acceptable degree through involvement in the atomic energy work of nonassociated private industry or the academic community. With few exceptions, technical personnel who have completed tours of duty abroad have been absorbed into AEC or AEC contractor organizations to the considerable benefit of the Government.

We would welcome an opportunity to discuss this matter further and should you wish to do so please feel free to contact Mr. Thomas O. Jones, Assistant Director for Administration, Division of International Affairs (phone: code 119, extension 4357).

Sincerely yours,

John A. Hall,
Assistant General Manager for International Activities.

A. Report, "AEC Foreign Office Operations."

B. "Arrangement Between the Department of State and the AEC for Stationing AEC Representatives Abroad."

Enclosure A

AEC Foreign Office Operations

1. Function of the offices

The Atomic Energy Commission established small overseas offices, attached or associated with U.S. Embassies, in order to facilitate close and continuing liaison with foreign atomic energy programs and to assist in carrying out the Commission's program of international cooperation, including the distribution of source, special, and byproduct nuclear materials, and the exchange of classified and unclassified information. All of the offices have the above general functions to some degree. Some may have a more specialized program than others depending on the sophistication of the foreign atomic energy programs with which associated.

2. Location of present offices, dates of establishment

Currently, the Atomic Energy Commission has six foreign offices located and established as follows:

Location:	Date of establishment
Chalk River, Ontario, Canada	November 1955.[1]
Paris, France	November 1956.
London, England	December 1956.
Buenos Aires, Argentina	November 1957.
Tokyo, Japan	Do.
Brussels, Belgium	November 1958.

[1] During World War II the Army's Corps of Engineers established a group at Chalk River, Ontario, to provide liaison with the Canadian atomic energy establishment. That office continued functioning after the war and at the time of the establishment of the Division of International Affairs in 1955 the Chalk River group was transferred to the new division.

At present, one employee of the Chalk River office is located at Pinawa, Manitoba, where he provides technical liaison and coordination principally with the Whiteshell Nuclear Research Establishment of Atomic Energy of Canada, Ltd.

3. Relation to State Department officials abroad

The Atomic Energy Commission's foreign offices were established pursuant to the "Arrangement Between the Department of State and the Atomic Energy Commission for Stationing Atomic Energy Commission Representatives Abroad" (enclosure B). In discharging the functions of their respective offices, the principal AEC representatives maintain close liaison with U.S. Ambassadors, other officials of the Department of State, and other Government agencies abroad to assure mutual coordination of activities. The AEC recognizes that the authority and responsibility of the Diplomatic Mission Chief is applicable to the relationships between the AEC representatives and the pertinent Ambassadors and their staffs.

4. Standards for selection of principal AEC representatives

Due to the varying degrees of complexity surrounding the responsibilities of the various principal AEC representative positions and in consideration of the degree of advancement of the atomic energy programs with which the representative will be associated, the standards for selecting personnel to fill the vacant principal representative positions may vary. Candidates for vacancies are considered with due regard to the demands of the job in each case. Selections are made by the Director, Division of International Affairs, with the approval of the General Manager and the Commission, based on the academic and professional experience of the candidates; their knowledge of U.S. and foreign atomic energy programs; and their linguistic ability. Knowledge of U.S. Government administrative and legislative operations and demonstrated diplomacy in handling contacts rank high as desirable qualifications.

Demonstrated ability and experience within the U.S. atomic energy program, of course, are considered prime requisites for these principal representative positions. The individual selected for a principal representative position must possess sufficient scientific and technical experience, as might be gained through employment with the USAEC or AEC contractor organizations, to permit his adequately fulfilling the technical requisites of the position. He may play an important role in the development of the atomic energy programs in the countries to which assigned. Accordingly, he must have a sound background to render meaningful advice and assistance to foreign programs. The head of each foreign office must also possess sufficient administrative experience and known ability to supervise the sometimes complex operations of a U.S. Government office in a foreign country.

Diplomacy is important since the individual will represent the United States in the atomic energy field and will deal directly with various levels of representatives of the governments and atomic energy programs of the countries to which accredited. Through these contacts they can do much to enhance U.S. prestige and to maintain a U.S. influence in the atomic energy programs.

5. Personnel policies relating to these overseas assignments

Recruiting for all vacant positions overseas is accomplished in accordance with the general personnel policy of the Atomic Energy Commission and in conformance with the specific policies, practices, and procedures as contained in AEC Manual chapters 4108, "Employment" and 4141, "Foreign and Territorial Employment."

It should be noted that all sources which are likely to yield candidates with required skills are utilized in filling vacancies. Examples of possible sources are: (*a*) employees of the AEC; (*b*) AEC contractors; (*c*) AEC consultants; (*d*) other Government agencies; (*e*) professional, technical, and scientific societies and organizations; (*f*) industrial organizations, and (*g*) colleges and universities. Since inception of the AEC's foreign office program a total of 22 principal representative vacancies have been filled. Of these, 18 were recruited from within the AEC; 2 from AEC contractor organizations; and 2 from other Government agencies. None were recruited from private industry or academic institutions not associated with the Government's atomic energy program.

6. Advantages to the AEC from assignment of its own staff rather than hire scientists from the academic community for a tour of duty

Due to the nature of the programmatic and administrative responsibilities of the principal AEC representatives abroad, it is important that each incumbent have a sufficient background of experience in the programs of the USAEC. This background can only be achieved through direct participation, particularly in the technical phases of such programs over a period of years. To this time we have filled vacancies from within the AEC and AEC contractor family. The advantages of recruitment from within the program are as follows: Candidates—

(*a*) Are technically trained both formally and on the job;

(*b*) Have extensive experience in the atomic energy field;

(*c*) Have familiarity with the typical Government operation; i.e., regulations, procedures, methods of operation, etc.;

(*d*) Have proven their leadership qualifications;

(*e*) Have demonstrated an acceptable level of diplomacy and tact in their personal relations;

(*f*) Have broad knowledge through experience of personnel in the Atomic Energy Commission and in its contractor organizations, as well as in the scientific community at home and abroad, who possess special administrative and technical abilities and who may be called upon as a need arises to provide expert advice and assistance;

(*g*) Currently possess or have possessed AEC "Q" clearance; and

(*h*) Can normally be made available for assignment on a convenient schedule.

7. Disadvantages, if any

There are few, if any, disadvantages to filling principal representative position vacancies from within the program. The reservoir of qualified technical personnel within the atomic energy program appears sufficient in relation to the relatively few principal representative position vacancies occurring. Prior to March 1965, tours of duty abroad were for 2-year periods, but now are generally for a period of 3 years. In most instances, principal representatives agree to an extension or a full second tour. Thus, vacancies in the top level positions have occurred at each post on an average of every 28 months.

8. Subsequent AEC employment of scientists and engineers returning from assignments to AEC overseas offices

It is AEC policy to provide continued employment within the agency, following a tour of duty abroad, to the extent that circumstances permit such continued employment. Employees are given intensive and appropriate consideration for placement in positions and at locations which are agreeable to the employee and, of course, most beneficial to the AEC.

Since inception of the AEC's foreign office program 16 persons who occupied principal representative positions have returned from duty abroad. Of these, only four left AEC service upon returning from their foreign assignments. All of the others have returned to responsible positions within the AEC headquarters.

ENCLOSURE B

ARRANGEMENT BETWEEN THE DEPARTMENT OF STATE AND THE ATOMIC ENERGY COMMISSION FOR STATIONING AEC REPRESENTATIVES ABROAD

1. *General.*—Under the provisions of the Atomic Energy Act of 1954 (Public Law 703, 83d Cong.) provision is made for various types of cooperation with foreign countries and for agreements with foreign counties concerning such cooperation. The Atomic Energy Commission (AEC) is engaged in an increasing

volume of activity in the field of cooperation with other governments. Approximately 36 countries have now signed agreements for cooperation with the United States, and agreements with additional countries are being negotiated.

The level of this activity now makes it appear that the Commission may need to station AEC representatives abroad in a few countries to assist it in connection with these cooperative activities. The purpose of this paper is to set forth the arrangements between the Department of State and the Commission in connection with such assignments.

2. *Duties of AEC representatives.*—The duties of the AEC representatives will be determined by AEC within the field of its functions and responsibilities. They will relate primarily to operations under the agreements for peaceful uses and would be predominantly technical in the atomic energy field. The AEC representatives will maintain contact with the atomic energy establishments of the countries to which accredited and will report on the technical aspects of atomic energy developments.

3. *Relationship of AEC representatives to the Ambassador.*—The AEC representative will work in full cooperation with the diplomatic mission chief and his staff and with the International Cooperation Administration missions or personnel where present. AEC recognizes that the authority and responsibility of the diplomatic mission chief as set forth in part II of Executive Order 10575 will be applicable to these relationships. The AEC representative will be available to assist the diplomatic mission in carrying out its diplomatic and reporting functions related to atomic energy, although State recognizes that AEC normally has first claim on his time and will undertake not to make unreasonable demands upon the time of the AEC representative.

4. *Negotiations with foreign governments.*—The Atomic Energy Commission recognizes the responsibility of the Department of State and the U.S. chief of diplomatic mission for conducting all negotiations with foreign governments and will instruct its representative to work in full cooperation with the mission chief and the diplomatic staff and to follow instructions of the mission chief with respect to any negotiations. At the same time, the State Department recognizes the responsibilities of AEC for cooperation with other governments in the atomic field and will instruct the chiefs of diplomatic mission to assist the AEC representatives in the development of those contacts with foreign officials which are necessary and reasonable in the execution of their duties for AEC.

5. *Further development of atomic energy functions overseas.*—It is recognized that atomic matters will be of growing importance in the conduct of foreign relations in the future and that the activities carried out overseas by the Atomic Energy Commission may also increase. The Department of State may find it necessary to assign to some posts full-time Department officers for political and economic problems related to atomic energy. AEC may find it necessary to increase its staff of representatives as the foreign activities for which it is responsible increase. The International Cooperation Administration also has certain responsibilities in the atomic energy field which will require attention by ICA field staff in the U.S. operations missions. In this developing situation, it is agreed that there should be continuing consultation between ICA, State, and AEC to assure that there is full understanding and cooperation in the fields of mutual interest, such as the reporting of foreign development, and to assure full and effective use of staff available abroad for functions related to atomic energy.

6. *Selection of AEC representatives.*—AEC representatives will be selected, paid, and assigned abroad by the Atomic Energy Commission. However, prior to making a commitment to assign an officer to a particular post, AEC will obtain the concurrence of the Department of State.

7. *Communications.*—State Department communications facilities will be used by the Atomic Energy Commission and its representatives. Chiefs of U.S. diplomatic missions and AEC representatives shall be expected to comply fully with the provisions of sections 201(b)(5) and 203(b) of Executive Order 10575 concerning communications.

8. *Administrative services.*—The State Department will provide to the AEC representatives office space, equipment, facilities, and administrative services in accordance with the approved policies and procedures of the State Department concerning administrative services for other departments and agencies and reimbursement for such services.
